From a comparison of those *Euchlorophyceæ* which have been most closely investigated, it appears probable that sexual reproductive cells have in the course of evolution arisen as the result of specialization among asexual reproductive cells, and that in turn oogamous reproduction has arisen as the result of differentiation of the two conjugating cells into the smaller male gamete and the larger female gamete. It would further appear that oogamous reproduction has arisen independently in each of the three main groups of *Euchlorophyceæ*, viz., *Protococcales*, *Siphonales*, and *Confervales*. Thus among *Volvocaceæ*, a family of *Protococcales*, while in some of the genera (*Chloraster*, *Sphondyliomorium*), no sexual union has as yet been observed, in others (*Pandorina*, *Chlorogonium*, *Stephanosphaera*, *Sphaerella*) conjugation of similar gametes takes place, in others still (*Phacotus*, *Eudorina*, *Volvox*) the union is of the nature of fertilization. No other family of *Protococcales* has advanced beyond the stage of isogamous reproduction. Again, among *Siphonales* only one family (*Vaucheriaceæ*) has reached the stage of oogamy, although an incipient heterogamy is said to occur in two other families (*Codiaceæ*, *Bryopsidaceæ*). Elsewhere among *Siphonales*, in those cases where reproductive cells are known, the reproduction is either isogamous or asexual. Among *Confervales* there is no family in which sexual reproduction—isogamy or oogamy—is not known to occur among some of the component species, and as many as four families (*Cylindrocapsaceæ*, *Sphaeropleaceæ*, *Edogoniaceæ*, *Coleochæteaceæ*) are oogamous. On these, as well as other grounds, *Confervales* are regarded as having attained to the highest rank among *Euchlorophyceæ*. Although the phenomena attending isogamous and oogamous reproduction respectively are essentially the same in all cases, slight variations in both instances appear in different families, attributable doubtless to the independent origin of the process in different groups. Thus, although isogamy consists in typical cases of a union of naked motile gametes by a fusion which begins at the beaked ends, and results in the formation of an immotile spherical zygote surrounded by a cell-wall, in *Leptostira* it is noticeable that the fusion begins at the blunt end; in a species of *Chlamydomonas* the two gametes are each included in a cell-wall before fusion; and in many cases the zygote retains for some time its motility with the double number of cilia. Again, in oogamous reproduction, while in general only one oosphere is differentiated in the oogonium, in *Sphaeroplea* several oospheres arise in each oogonium; and while the oospheres usually contract away from the oogonial wall, acquiring for themselves a new cell-wall after fertilization, in *Coleochæte* the oosphere remains throughout in contact with the oogonial wall. The oosphere is in all cases fertilized while still within the oogonium, the antherozoids being admitted by means of a pore. There is usually distinguishable upon the surface of the oosphere an area free from chlorophyll, known as the receptive spot, at which the fusion with the antherozoid takes place; and in many cases, before fertilization, a small mucilaginous mass has been observed to separate itself off from the oosphere at this point and to escape through the pore. In *Coleochæte* the oogonial wall is drawn out into a considerable tube, which is provided with an apical pore, and this tube has a somewhat similar appearance to the imperforate trichogyne of *Floridææ* to be hereafter described. In certain species of *Edogonium* minute male plantlets, known as dwarf males, become attached to the female plant in the neighbourhood of the oogonia, thus facilitating fertilization. Indeed the genus *Edogonium* exhibits a high degree of specialization in its reproductive system, considering that its thallus has not advanced beyond the stage of an unbranched filament.

Many *Euchlorophyceæ* are endowed with both asexual and sexual reproduction. Such are *Coleochæte*, *Edogonium*, *Cylindrocapsa*, *Ulothrix*, *Vaucheria*, *Volvox*, &c. In others only the asexual method is yet known. When a species resorts to both methods, it is generally found that the asexual method prevails in the early part of the vegetative period, and the sexual towards the close of that period. This is in consonance with the facts already mentioned that zoospores germinate forthwith, and that the sexually-produced cell or zygote enters upon a period of rest. It is known that zoogametes, which usually conjugate, may, when conjugation fails, germinate directly (*Sphaerella*). In rare cases the oosphere has been known to germinate without fertilization (*Edogonium*, *Cylindrocapsa*). The germination of a zygospore or oospore is effected by the rupture of an outer cuticularized exosporium; then

the cell may protrude an inner wall, the endosporium, and grow out into the new plant (*Vaucheria*), or the contents may break up into a first brood of zoospores. It is held that in *Coleochaete* a parenchyma results from the division of the oospore, from each cell of which a zoospore arises.

Reproduction is also effected among *Euchlorophyceæ* by means of aplanospores and akinetes. Aplanospores would seem to represent zoospores arrested in their development; without reaching the stage of motility, they germinate within the sporangium. Akinetes are ordinary thallus cells, which on account of their acquisition of a thick wall are capable of surviving unfavourable conditions. Both aplanospores and akinetes may germinate with or without the formation of zoospores at the initial stage.

Among *Conjugatæ* reproduction is effected solely by means of conjugation of what are literally aplanospores. Among those *Desmidiaceæ*, which live a free life, two plants become surrounded by a common mucilage, in which they lie either parallel (*Closterium*) or crosswise (*Cosmarium*). Gaps then appear in the apposed surfaces, usually at the isthmus; the entire protoplasts either pass out to melt into one another clear of the old walls, or partly pass out and fuse without complete detachment from the old walls. Among colonial *Desmidiaceæ*, the break-up of the filament is a preliminary to this conjugation; otherwise the process is the same. The zygosporium becomes surrounded with its own wall, consisting finally of three layers, the outer of which is furnished with spicular prominences of various forms. In *Zygnemaceæ* there is no dissolution of the filaments, but the whole contents of one cell pass over by means of a conjugation-tube into the cavity of a cell of a neighbouring filament, where the zygosporium is formed by the fusion of the two protoplasts. In these cases the activity of one of the gametes, and the passivity of the other, is regarded as evidence of incipient sex. In *Strogonium* there is cell-division in the parent-cell prior to conjugation; and as two segments are cut off in the case of the active gamete, and only one in the case of the passive gamete, there is a corresponding difference of size, marking another step in the sexual differentiation. In *Zyogonium*, although no cell-division takes place, the gametes consist of a portion only of the contents of a cell, and this is regularly the case in *Mesocarpaceæ*, which occupy the highest grade among *Conjugatæ*. Some *Zygnemaceæ* and *Mesocarpaceæ* form either a short conjugating tube, or none at all, but the filaments approach each other by a knee-like bend, and the zygosporium is formed at the point of contact, often being partially contained within the walls of the parent-cell. It would seem that in some cases the nuclei of the gametes remain distinct in the zygosporium for a considerable time after conjugation. It is probable that in all cases nuclear fusion takes place sooner or later. In *Zygnemaceæ* and *Mesocarpaceæ* the zygosporium, after a period of rest, germinates, to form a new filamentous colony; in *Desmidiaceæ* its contents divide on germination, and thus give rise to two or more Desmids. Gametes which fail to conjugate sometimes assume the appearance of zygosporia and germinate in due course. They are known as azygosporia.

The reproduction of *Characeæ* is characterized by a pronounced oogamy, the reproductive organs being the most highly differentiated among *Chlorophyceæ*. The antheridia and oogonia are formed at the nodes of the appendages. The oogonium, seated on a stalk cell, is surrounded by an investment consisting of five spirally-wound cells, from the projecting ends of which segments are cut off, constituting the so-called stigma. The oosphere is not differentiated within the wall of the oogonium, but certain cells known as *wendungszellen*, the significance of which has given rise to much speculation, are cut off from the basal portion of the parent-cell during its development. The antheridia are spherical, orange-coloured bodies of very complex structure. The antherozoid is a spirally-coiled thread of protoplasm, furnished at one end with a pair of cilia. It much more resembles the antherozoids of *Bryophyta* and certain *Pteridophyta* than any known among other Algae. The fertilized egg charged with food reserves rests for a considerable period, surrounded by its cortex, the whole having assumed a reddish-brown colour. On germination it gives rise to a row of cells in which short (nodal) and long (internodal) cells alternate. From the first node arise rhizoids; from the second a lateral bud, which becomes the new plant. This peculiar product of germination, which intervenes between the oospore and the adult form, is the proembryo. It will be remembered that in *Musci* the asexual spore somewhat similarly gives rise to a protonema, from which the adult plant is produced as a lateral bud. The proembryonic branches of *Characeæ*, one of the means of vegetative reproduction already referred to, are so called because they repeat the characters of the proembryo.

Before leaving the *Chlorophyceæ*, it should be mentioned that the genus *Volvox* has been included by some zoologists (Bütschli, for example) among *Flagellata*; on the other hand, certain green *Flagellata*, such as *Euglena*, are included by some botanists (for example, van Tieghem) among unicellular plants. A similar

uncertainty exists with reference to certain groups of *Phæophyceæ*, and the matter will thus arise again.

3. **PHÆOPHYCÆÆ.**—The *Phæophyceæ* are distinguished by the possession of a brown colouring matter, phycophæin, in addition to chlorophyll. They consist of the following groups:—*Fucaceæ*, *Phæosporeæ*, *Dictyotaceæ*, *Cryptomonadaceæ*, *Peridiniaceæ*, and *Diatomaceæ*. Of these the first three include multicellular plants, some of them of great size; the last three are unicellular organisms, with little in common with the rest excepting the possession of a brown colouring matter. *Fucaceæ* and *Phæosporeæ* are doubtless closely allied, and to these *Dictyotaceæ* may be joined, though the relationship is less close. They constitute the *Euphæophyceæ*, and will be dealt with in the first place.

Euphæophyceæ are almost exclusively marine, growing on rocks and stones on the coast, or epiphytic upon other Algae. In tidal seas they range from the limits of high water to some distance beyond the low-water line. On the British coasts zones are observable in passing from high- to low-water mark, characterized by the prevalence of different species, thus:—*Pelvetia canaliculata*, *Fucus platycarpus*, *Fucus vesiculosus*, *Ascophyllum nodosum*, *Fucus serratus*, *Laminaria digitata*. Some species are minute filamentous plants, requiring the microscope for their detection; others, like *Lessonia*, are of considerable bulk; or, like *Macrocystis*, of enormous length. In *Fucaceæ*, *Dictyotaceæ*, and *Laminariaceæ* and *Sphacelariaceæ*, among *Phæosporeæ*, the thallus consists of a true parenchyma; elsewhere it consists of free filaments, or filaments so compacted together, as in *Cutleriaceæ* and *Desmarestiaceæ*, as to form a false parenchyma. In *Fucaceæ* and *Laminariaceæ* the inner tissue is differentiated into a conducting system. In *Laminariaceæ* the inflation of the ends of conducting cells gives rise to the so-called trumpet-hyphæ. In *Nereocystis* and *Macrocystis* a zone of tubes occurs which present the appearance of sieve-tubes even to the eventual obliteration of the perforations by a callus. While there is a general tendency in the group to mucilaginous degeneration of the cell-wall, in *Laminaria digitata* there are also glands secreting a plentiful mucilage. Secondary growth in thickness is effected by the tangential division of superficial cells. The most fundamental external differentiation is into holdfast and shoot. In *Laminariaceæ* secondary cylindrical props arise obliquely from the base of the thallus. In epiphytic forms the rhizoids of the epiphyte often penetrate into the tissue of the host, and certain epiphytes are not known to occur excepting in connexion with a certain host; but to what extent, if any, there is a partial parasitism in these cases has not been ascertained. In filamentous forms there is a differentiation into branches of limited and branches of unlimited growth (*Sphacelaria*). In *Laminariaceæ* there is a distinction of stipe and blade. The blade is centrally-ribbed in *Alaria* and laterally-ribbed in *Macrocystis*. It is among the *Sargassaceæ* that the greatest amount of external differentiation, rivaling that of the higher leafy plants, is reached. A characteristic feature of the more massive species is the occurrence of air-vesicles in their tissues. In *Fucus vesiculosus* they arise in lateral pairs; in *Ascophyllum* they are single and median; in *Macrocystis* one vesicle arises at the base of each thallus segment; in *Sargassum* and *Hatidryis* the vesicles arise on special branches. They serve to buoy up the plant when attached to the sea-bottom, and thus light is admitted into the forest-like growths of the gregarious species. When such plants are detached they are enabled to float for great distances, and the great Sargasso Sea of the North Atlantic Ocean is probably only renewed by the constant addition of plants detached from the shores of the Caribbean Sea and Gulf of Mexico.

Growth in length is effected in a variety of ways. In *Dictyota*, *Sphacelariaceæ*, and *Fucaceæ* there is a definite apical cell. In the first it is a biconvex lens, from which segments are continually cut off parallel to the posterior surface; and in the second an elongated dome, from which segments are cut off by a transverse wall. While, however, in *Dictyota* the product of the subsequent division in the segment enlarges with each subdivision, the divisions in the cylindrical segment of *Sphacelariaceæ* are such that the whole product after subdivision, however many cells it may consist of, does not exceed in bulk the segment as cut off from the apical cell. In *Dictyotaceæ* the apical cell occasionally divides

1 **Phæophyceæ** include:—

1. *Cyclosporinæ* (*Fucaceæ*)—4 families, 32 genera, 347 species.
2. *Tetrasporinæ* (*Dictyotaceæ*)—1 family, 17 genera, 130 species.
3. *Phæozoosporinæ* (*Phæosporeæ*)—24 families, 143 genera, 571 species.

(De Toni's *Sylogæ Algarum*.)

4. *Peridinales*—3 families, 32 genera, 167 species.
5. *Cryptomonadaceæ* (including *Chryomonadaceæ*)—2 families, 28 genera, 50-60 species.
6. *Bacillariales* (*Diatomaceæ*)—about 150 genera, and 5000 species, fossil and recent.

(Engler and Prantl's *Pflanzenfamilien*.)

longitudinally, and thus the dichotomous branching is provided for. In some *Sphacelariaceæ* branches may appear at their inception as lateral protuberances of the apical cell itself. In *Fucaceæ* an apical cell is situate at the surface of the thallus in a slit-like depression at the apex. From this cell segments are cut off in three or four lateral oblique planes.

A peculiar manner of growth in length is that to which the term trichothallic has been applied. It may readily be observed that in the hair-like branches of *Ectocarpaceæ*, the point at which most rapid division occurs is situate near the base of the hair. In *Desmarestia* and *Arthrocladia*, for example, it is found that the thallus ends in a tuft of such hairs, each of them growing by means of an intercalated growing point. In these cases, however, the portions of the hairs behind the growing region become agglutinated together into a solid cylindrical pseudo-parenchymatous axis. In *Cutleria* the laminated thallus is formed in the same way. The intercalated growing region of *Laminaria* affords an example of another variety of growth in *Phaeophyceæ*. While the laminated portion of the thallus is being gradually worn off in our latitudes during the autumnal storms, a vigorous new growth appears at the junction of the stipe and the blade, as the result of which a new piece is added to the stipe and the lamina entirely renovated.

Both asexual and sexual reproduction occur among *Euphæophyceæ*. *Fucaceæ* are marked by an entire absence of the asexual method. The sexual organs—oogonia and antheridia—are borne on special portions of the thallus in cavities known as conceptacles. Both organs may occur in one conceptacle, as in *Pelvetia*, or each may be confined to one conceptacle or even one plant, as in *Fucus vesiculosus*. The oogonia arise on a stalk cell from the lining layer of the cavity, the contents dividing to form eight oospores as in *Fucus*, four as in *Ascophyllum*, two as in *Pelvetia*, or one only as in *Halidryis*. It would seem that eight nuclei primarily arise in all *Fucaceæ*, and that a number corresponding to the number of oospores subsequently formed is reserved, the rest being discharged to the periphery, where they may be detected at a late stage. On the maturation of the oospores the outer layer of the oogonial wall ruptures, and the oospores, still surrounded by a middle and inner layer, pass out through the mouth of the conceptacle. Then usually these layers successively give way, and the spherical naked oospores float free in the water. The antheridia, which arise in the conceptacular cavity as special cells of branched filaments, are similarly discharged whole, the antherozoids only escaping when the antheridia are clear of the conceptacle. The antherozoids are attracted to the oospores, round each of which they swarm in great numbers. Suddenly the attraction ceases, and the oospore is fertilized, probably at that moment, by the entry of a single antherozoid into the substance of the oospere; a cell-wall is formed thereupon, in some cases in so short an interval as five minutes. Remarkable changes of size and outline of the oospere have recently been described as accompanying fertilization in *Halidryis*. Probably the act of fertilization in plants has nowhere been observed in such detail as in *Fucaceæ*. *Dictyotaceæ* resemble *Fucaceæ* in their pronounced oogamy. They differ, however, in being also asexually reproduced. The asexual cells are immotile spores arising in fours in sporangia from superficial cells of the thallus. In *Dictyota* the oospores arise singly in oogonia, crowded together in sori on the surface of the female plant. The antheridia have a similar origin and grouping on the male plant. Until the recent discovery by Williams of motility, by means of a single cilium, of the antherozoids of *Dictyota* and *Taonia*, they were believed to be immotile bodies, like the male cells of red seaweeds. In *Dictyota* the unfertilized oospere is found to be capable of undergoing a limited number of divisions, but the body thus formed appears to atrophy sooner or later.

Of the small family of the *Tilopteridaceæ* our knowledge is as yet inadequate, but they probably present the only case of pronounced oogamy among *Phaeosporeæ*. They are filamentous forms, exhibiting, however, a tendency to division in more than one plane, even in the vegetative parts. The discovery by Brehner of the specific identity of *Haplospora globosa* and *Scaphospora speciosa* marks an important step in the advance of our knowledge of the group. Three kinds of reproductive organs are known: first, sporangia, which each give rise to a single tetra-, or multinucleate non-motile, probably asexual spore; second, plurilocular sporangia, which are probably antheridia, generating antherozoids; and third, sporangia, which are probably oogonia, giving rise to single uninucleate non-motile oospores. No process of fertilization has as yet been observed.

The *Cutleriaceæ* exhibit a heterogamy in which the female sexual cell is not highly specialized, as it is in the groups already described. From each locule of a plurilocular sporangium there is set free an oospere, which, being furnished with a pair of cilia, swarms for a time. In similar organs on separate plants the much smaller antherozoids arise. Fertilization has been observed at Naples; but it apparently depends on climatic con-

ditions, as at Plymouth the oospores have been observed to germinate parthenogenetically. The asexual organs in the case of *Cutleria multifida* arise on a crustaceous form, *Aglaozonia reptans*, formerly considered to be a distinct species. They are unilocular, each producing a small number of zoospores.

The possession of two kinds of reproductive organs, unilocular and plurilocular sporangia, is general among the rest of the *Phaeosporeæ*. Bornet, however, called attention in 1871 to the fact that two kinds of plurilocular sporangia occurred in certain species of the genus *Ectocarpus*—somewhat transparent organs of an orange tint producing small zoospores, and also more opaque organs of a darker colour producing relatively larger zoospores. On the discovery of another such species by Buffham, Batters in 1892 separated the three species, *Ectocarpus secundus*, *E. fenestratus*, *E. Lebelli*, together with the new species, into a genus, *Giffordia*, characterized by the possession of two kinds of plurilocular sporangia. The suspicion that a distinction of sex accompanied this difference of structure has been justified by the discovery by Sauvageau of undoubted fertilization in *Giffordia secunda* and *G. fenestrata*. The conjugation of similar gametes, arising from distinct plurilocular sporangia, was observed by Berthold in *Ectocarpus siliculosus* and *Scytosiphon lomentarius* in 1880; and these observations have been recently confirmed in the case of the former species by Sauvageau, and in the case of the latter by Kuckuck. In these cases, however, the potential gametes may, failing conjugation, germinate directly, like the zoospores derived from unilocular sporangia. The assertion of Areschoug that conjugation occurs among zoospores derived from unilocular sporangia, in the case of *Dictyosiphon hippuroides*, is no doubt to be ascribed to error of observation. It would thus seem that the explanation of the existence of two kinds of sporangia, unilocular and plurilocular, among *Phaeosporeæ*, lies in the fact that unilocular sporangia are for asexual reproduction, and that plurilocular sporangia are gametangia—potential or real. It must, however, be remembered that so important a generalization is as yet supported upon a somewhat narrow base of observation. Moreover, for the important family of the *Laminariaceæ* only unilocular sporangia are known to occur; and for many species of other families, only one or other kind, and in some cases neither kind, has hitherto been observed. The four species—*Ectocarpus siliculosus*, *Giffordia secunda*, *Cutleria multifida*, and *Haplospora globosa*—may be taken to represent, within the *Phaeosporeæ*, successive steps in the advance from isogamy to oogamy.

The *Peridiniaceæ* have been included among *Flagellata* under the title of *Dinoflagellata*. The majority of the species belong to the sea, but many are found in fresh water. The thallus is somewhat spherical and unicellular, exhibiting a distinction between anterior and posterior extremities, and dorsal and ventral surfaces. The wall consists of a basis of cellulose, and in some cases readily breaks up into a definite number of plates, fitting into another like the plates of the carapace of a tortoise; it is, moreover, often finely sculptured or coarsely ridged and flanged. Two grooves are a constant feature of the family, one running transversely and another longitudinally. In these grooves lie two cilia, attached at the point of meeting on the dorsal surface. The protoplast is uninucleate and vacuolate, and contains chromatophores of a brownish colour. It is not clear that the brown colouring matter which is added to chlorophyll is identical with phycophæin; two varieties of it have been termed phycopyrin and peridinine. Certain species such as *Gymnodinium spirale*, are colourless and therefore saprophytic in their method of nutrition. Multiplication takes place in some cases by the endogenous formation of zoospores, the organism having come to rest; in others by longitudinal division, when the organism is still motile. No method of sexual reproduction is known with certainty.

The *Cryptomonadaceæ* also are unicellular, and live free or in colonies. Each cell contains a flattened chromatophore of a brown or yellow colour. *Hydrurus* forms a branched gelatinous colony attached to stones in mountain streams. *Chromophyton* form an eight-celled colony. Both plants multiply solely by means of zoospores. The *Cryptomonadaceæ* and *Chromulinæ* are motile through the greater part of their life. *Cryptomonas*, when dividing in a mucilage after encystment, recalls the condition in *Glaucocystis*. In *Synura* and *Chromulina* the cells form a spherical motor colony, recalling *Volvocaceæ*. *Chromulina* is uniciliate and is contained in the hyaline capsule. Like the *Peridiniaceæ*, the *Cryptomonadaceæ* have been included among *Flagellata*. They have no close affinity with *Euphæophyceæ*. Such colonial forms as *Hydrurus* and *Phaeocystis* are supposed, however, to indicate a stage in the passage to the multicellular condition.

Diatomaceæ have long been recognized as plants. Together with *Peridiniaceæ* they constitute the bulk of marine plankton, and thus play an important part in the support of marine animal life. They exhibit striking adaptations in these circumstances to the floating habit. (See DIATOMACEÆ, ninth ed.)

4.—RHODOPHYCÆ, or FLORIDEÆ.¹—The members of this group are characterized by the possession of a red colouring-matter, phycoerythrin, in addition to chlorophyll. There is, however, a considerable amount of difference in the shades of red which mark different species. The brightest belongs to those species which grow near low-water mark, or under the shade of larger Algæ at higher levels; species which grow near high-water mark are usually of so dark a hue that they are easily mistaken for brown seaweeds. *Rhodophycæ* are mostly marine, but not exclusively so. *Thorea*, *Lemanea*, *Tuomeya*, *Stenocladia*, *Batrachospermum*, *Balbiana*, are genera belonging entirely to fresh water; and *Bangia*, *Chantransia*, *Caloglossa*, *Bostrychia*, and *Delesseria* contain each one or more fresh-water species. Most of the larger species of marine *Rhodophycæ* are attached by means of a disc to rocks, stones, or shells. Many are epiphytic on other Algæ, more especially the larger *Phæophycæ* and *Rhodophycæ*. As in the case of epiphytic brown seaweeds, the rhizoids of the epiphyte often penetrate the substance of the supporting Alga. Some Red Algæ find a home in the gelatinous substance of *Flustra*, *Alcyonidium*, and other polyzoa, only emerging for the formation of the reproductive organs. Some are perforating Algæ and burrow into the substance of molluscan shells, in company with certain Green and Blue-green Algæ. Some species belonging to the families *Squamariaceæ* and *Corallinaceæ* grow attached through their whole length and breadth, and are often encrusted with lime. The forms which grow away from the substratum vary greatly in external configuration. In point of size the largest cannot rival the larger Brown Algæ, while the majority require the aid of the microscope for their investigation.

No unicellular *Rhodophycæ* are known, although a flagellate organism, *Rhodomonas*, has recently been described as possessed of the same red colouring-matter. If the sub-group, *Bangiaceæ*, be excluded, they may be said to consist exclusively of branched filaments. Growth in these cases takes place by means of an apical cell, from which successive segments are cut off by means of a transverse wall. The segment so cut off does not usually divide again by means of a transverse wall, nor indeed by a longitudinal wall which passes through the organic axis of the cell. New cells may be cut off laterally, which become the apical cells of branches. When the new cells grow no further, but constitute a palisading round the central cell covering its whole length, the condition is reached which characterizes the species of *Polysiphonia*, the "siphons" of which may be regarded as one-celled branches. To the law that no subsequent transverse division takes place in segments cut off from the apical cell, there seem to be two exceptions: first, the calcareous genus *Corallina*, in the pliable joints of which intercalated division occurs; and, second, the *Nitophylleæ*, in which, moreover, median longitudinal division of axial cells is said to occur. Like the Fungi, therefore, the Red Algæ consist for the most part of branched filaments, even where the thallus appears massive to the eye, and, as in the case of Fungi, this fact is not inconsistent with a great variety of external morphology. In the great majority the thallus is obviously filamentous, as in some species of *Callithamnion*. In other species of that genus an apparent cortication arises by the downward growth of rhizoids, which are retained within the gelatinous wall of the axial cells. In *Batrachospermum* the whole system of branches are retained within a diffused gelatinous substance derived from the outer layers of the cell-walls. In other cases the mucilage is denser and the branches more closely compacted (*Helminthora*). In such cases as *Lemanea*, the terminal cells of the lateral branches form a superficial layer which has all the appearance of a parenchyma when viewed from the surface. In *Champia* and allied genera, the cylindrical axis is due not to the derivatives of one axial filament, but of several, the growth of which is co-ordinated to form a septated tube. The branching of the thallus, which meets the eye in all these cases, is due to the unlimited growth of a few branches. When such a lateral branch overtops the main axis whose growth has become limited, as in *Plocamium* and *Dasya*, a sympodium is formed. For the most part the branching is monopodial. Besides the differentiation into holdfast and shoot, and into branches of limited and branches of unlimited growth, there appear superficial structures of the nature of hairs. These are for the most part long, thin-walled, unicellular, and colourless, and arise from the outer cells of the pseudo-cortex, or from the terminal cells of branches when the filaments are free. Among *Rhodomelaceæ*, hair-like structures of a higher order are known. These arise from the axial cell, and are multicellular and branched. They soon fall off, and it is from the

persistent basal cell that the branches of unlimited growth arise. Upon them also the reproductive organs arise in this family. It is not surprising, therefore, that they have been regarded as the rudiments of leaves. In *Iridæa* the thallus is an entire lamina; in *Callophyllis* a lobed lamina; in *Delesseria* it is provided with midrib and veins, simulating the appearance of a leaf of the higher plants; in *Constantinea* the axis remains cylindrical, and the lateral branches assume the form of leaves. In the compact thallus a secondary development often takes place by the growth of rhizoid-like internal filaments. They present a hypha-like appearance, running longitudinally for considerable distances. It is not difficult in such compact species to distinguish between superficial cells, whose chief function is assimilation, subjacent cells charged with reserve material, and a core of tissue engaged in the convection of elaborated material from part to part.

An interesting feature of the minute anatomy of *Erythroidea*, as the Red Algæ, exclusive of the *Bangiaceæ*, have been termed, is the existence of the so-called *Floridean pit*. When a cell divides it is found that there remains in the middle of the new wall a single large circular pit, which persists throughout the life of the cells, becoming more and more conspicuous with the progress of the thickening of the wall. These pits serve to indicate the genetic relationship of adjacent cells, when they form a compact pseudo-parenchyma, notwithstanding the fact that somewhat smaller secondary pits appear later between any contiguous cells. Protoplasmic continuity has been observed in the delicate membrane closing the pit.

Vegetative multiplication occurs only sparingly in *Rhodophycæ*. *Melobesia callithamnoides* gives rise to multicellular propagula; *Griffithsia corallina* is said to give rise to new individuals, by detaching portions of the thallus from the base of which new attachment organs have already arisen. The spores of *Monospora* are by some regarded as unicellular propagula. Reproduction is both asexual and sexual. It is noteworthy that although all the members of the group are aquatic no zoospores are produced, a negative character common to them and the Blue-green Algæ. As a rule the asexual cells and the male and female sexual cells arise upon different plants, so that the species may be said to be triceious. Numerous exceptions, however, occur. Thus in *Lemaneaceæ* asexual spores are unknown; in *Batrachospermum*, *Bonnemaisonia*, and *Polysiphonia byssoides* both kinds of sexual cells appear on the same plant; and in some cases the asexual cells may occur in conjunction with either the male or female sexual cells. The asexual cells are termed tetraspores on account of the usual occurrence of four in each sporangium. What may be termed monospores, bispores, and octospores, however, are not unknown. The sporangia may be terminal or intercalated. When they are confined to special branches, such branches are spoken of as stichidia. The tetraspores may arise by the simultaneous division of the contents of a sporangium, when they are arranged tetrahedrally, or they may arise by two successive divisions, in which case the arrangement may be zonate when the spores are in a row, or cruciate when the second divisions are at right angles to the first, or tetrahedral when the second divisions are at right angles to the first and also to one another. Tetraspores are at first naked, but soon acquire a cell-wall and germinate without a period of rest. The male sexual cells are produced singly in the terminal cells of branches. They are spoken of as spermatia. Great numbers of antheridia are usually crowded together, when the part is distinguishable by the absence of the usual red colour. In *Polysiphonia* they cover the joints of the so-called leaves; in *Chondria* they arise on flattened discs; in the more massive forms they arise in patches on the ordinary surface; in a few cases (*Gracilaria*, *Corallina*, *Galaxaura*) they line the walls of conceptacle-like depressions. The female sexual cell is represented by the contents of a cell which is terminal on ordinary or specialized branches. This is the carpogonium; it consists of a ventral portion which contains a nucleus, but in which no oosphere is differentiated, and an elongated tubular portion known as the trichogyne, into which the cytoplasm extends. Fertilization is effected by the passive convection of a spermatium from the antheridium to the trichogyne, to which it adheres, and to which it passes over its nucleus through an open communication set up at the point of contact. The nucleus then passes down the trichogyne and fuses with that of the egg. This fusion has been observed by Wille in *Nemalion multifidum*, and by Schmidle in *Batrachospermum*. It is singular that in the last-named species two nuclei occur regularly in the spermatium. The ventral portion of the carpogonium may be imbedded deep in the thallus in the massive species; the trichogyne, however, always reaches the surface. The first effect of fertilization is the occlusion of the trichogyne from the fertilized carpogonium. The subsequent course of development is characteristic of the *Florideæ*. The carpogonium germinates forthwith, drawing its nourishment almost wholly from the parent plant. The ultimate product in all cases is a number of carpospores, but before this stage

¹ These include:—

1. *Bangiaceæ*—4 families, 9 genera, 58 species.
2. *Nemalioninæ*—4 families, 33 genera, 343 species.
3. *Gigartininæ*—3 families, 54 genera, 409 species.
4. *Rhodymeninæ*—4 families, 92 genera, 602 species.

(De Toni's *Sylloge Algarum*.)

is reached the development is different in different sub-groups. In *Batrachospermum* filaments arise from the carpogonium on all sides; in *Chantransia* and *Sesnaia* on one side only; in *Helminthora* the filaments are enclosed in a dense mucilage; in *Nemalion*, prior to the formation of the filaments, a sterile segment is cut off below. In all these cases, however, the end-cells of the filaments each give rise to a carpospore, and the aggregate of such sporiferous filaments is a cystocarp. Again, in the family of the *Gelidiaceæ*, the single filament arising from the carpogonium grows back into the tissue and preys upon the cells of the axis and larger branches, after which the end-cells give rise to carpospores and a diffused cystocarp is formed. In the whole group of the *Cryptonemiales* the parasitism becomes more marked still. The filaments arising from the carpogonia grow into long thin tubes, which fuse with special cells rich in protoplasm contents; and from these points issue isolated tufts of sporogenous filaments, several of which may form the product of one fertilized female cell. In *Naccaria*, one of the *Gelidiaceæ*, it is observable that the ooblastema filament, as the tube arising from the fertilized carpogonium has been called, fuses completely with a cell contiguous to the carpogonium before giving rise to the foraging filaments already referred to. This is also the case among *Cryptonemiales*. In a whole series of Red Algæ, the existence of a highly-specialized auxiliary cell in the neighbourhood of the carpogonium is a characteristic feature. In the *Gigartinales* it is already differentiated previous to fertilization; in *Rhodymeniales* it arises subsequent to fertilization. In the *Gigartinales*, the filaments which arise from the auxiliary cell may spread and give rise to isolated tufts of sporogenous filaments, as in the *Cryptonemiales*. In the *Rhodymeniales* a single tuft arises directly from the auxiliary cell. The carpospores are in all cases bright red naked masses of protoplasm when first discharged. They soon acquire a cell-wall, and germinate without a period of rest. When the cystocarps or segments of cystocarps are formed in the substance of a thallus, the site is marked merely by a swelling of the substance. When the cystocarp is produced externally, it may form a berry-like mass without an envelope, in which case it is known as a favella. In *Rhodomelaceæ* there is a special urn-shaped envelope surrounding the sporogenous filaments. This is a ceramidium.

The attachment of the cell of an ooblastema filament to a cell of the thallus may be effected by means of a minute pore, or the two cells may fuse their contents into one protoplasmic mass. In the latter case, and especially where the union is with a special auxiliary cell, it is of importance to know what happens to the nuclei of the fusing cells. Schmitz was of opinion that in the cases of open union there occurred a fusion of nuclei similar to that which occurs in the sexual union of two cells. He founded his generalization to a large extent upon the observation that in *Glaosiphonia capillaris* two cells completely fuse, and that only one nucleus can be detected in the fused mass. Oltmanns has recently reinvestigated the phenomena in this plant, among others, and has shown that the nucleus of the cell which is being preyed upon recedes to the wall and gradually atrophies. The nucleus of the ooblastema filament dominates the mass, and from it all the nuclei of the carpospores are thus derived. There thus seems to be no justification for believing, as Schmitz taught, that a second sexual act occurs in the life-cycle of these *Florideæ*.

The *Bangiæ* are a relatively small group of Red Algæ, to which much of the description now given does not apply. Structurally they are either a plate of cells, as in *Porphyra*, or filaments, as in *Bangia*. There is no exclusive apical growth, and the cells divide in all directions. The characteristic pit is also absent. Sexual and asexual reproduction prevail. The male cell is a spermatium, but the female cell bears no such receptive trichogyne as occurs in other *Rhodophyceæ*. After fertilization the equivalent of the oospore divides directly to form a group of carpospores. There is thus a certain resemblance to *Euflorideæ*, but sufficient difference to necessitate their being grouped apart. Fertilization by means of non-motile spermatia and a trichogyne are known among the *Fungi* in the families *Collema* and *Laboulbentia*.

After this survey of the four groups comprised under Algæ, it is easier to indicate the variations in the limits of the class as defined by different authorities. To consider the *Cyanophyceæ* first, either the marked contrast in the method of nutrition of the generally colourless *Bacteriaceæ* to that of the blue-green *Cyanophyceæ* is regarded as sufficient ground for

excluding *Bacteriaceæ* from Algæ altogether, notwithstanding their acknowledged morphological affinity with *Cyanophyceæ*, or, in recognition of the incongruity of effecting such a separation, the whole group of the *Schizophyta*—that is to say, the *Cyanophyceæ* in the narrow sense, together with *Bacteriaceæ*, is included or excluded together. Again, while *Conjugatæ* may be shut out from *Chlorophyceæ* as an independent group co-ordinate with them in rank, the *Characeæ* constitute so aberrant a group that it has even been proposed to raise them as *Charophyta* to the dignity of a main division co-ordinate with *Thallophyta*. Similarly, while *Diatomaceæ* may be excluded from among *Phæophyceæ*, though retained among Algæ, the *Cryptomonadaceæ* and *Peridiniaceæ*, like *Euglena* and other *Chlorophyceæ*, may be excluded from *Thallophyta* and ranged among the Flagellate *Protozoa*. (See *PROTOZOA*.) It is doubtful, however, whether the conventional distinction between plants and animals will continue to be urged; and the suggestion of Hæckel that a class *Protista* should be established to receive the forms exhibiting both animal and plant affinities has much to recommend it on phylogenetic grounds. To adopt a figure, it is probable that the sources from which the two streams of life—animal and vegetable—spring may not be separable by a well-defined watershed at all, but consist of a great level upland, in which the waterways anastomose. Finally, while *Chlorophyceæ* and *Phæophyceæ* exhibit important affinities, the *Rhodophyceæ* are so distinct that the term Algæ cannot be made to include them, except when used in its widest sense.

It has been well said that the attempt to classify plants according to their natural affinities is an attempt to construct for them the genealogical tree by which their relationships can be traced. Algæ are, *Phylogeny*, however, so heterogeneous a class, of which the constituent groups are so inadequately known, that it is at present futile to endeavour thus to exhibit their pedigree. A synoptical representation of the present state of knowledge would be expressed by a network rather than by a tree. The following table is an adaptation of a scheme devised by Klebs, and indicates the inter-relationships of the various constituent groups. The area

included in the thick boundary line represents Algæ in the widest sense in which the term is used, and the four included areas the four main subdivisions. A continuous line indicates a close affinity, and a dotted line a doubtful relationship.

In comparing Algæ with the great Archegoniate series which has doubtless sprung from them, it is natural to inquire to what extent, if any, they present evidence of the existence of the marked alternation of generations which dominates the life-history of the higher plants. Turning first to the *Rhodophyceæ*, both on account of the high place which

Alternation of generations.

they occupy among Algæ and also the remarkable uniformity in their reproductive processes, it is clear that, as is the case among *Archegoniata*, the product of the sexual act never germinates directly into a plant which gives rise to the sexual organs. Even among *Bangiaceæ* the carpospores arise from the fertilized cell by division, while in all other *Rhodophyceæ* the oospore, as it may be called, gives rise to a filamentous structure, varying greatly in its dimensions, epiphytic, and to a large extent parasitic upon the egg-bearing parent plant, and in the end giving rise to carpospores in the terminal cells of certain branches. There is here obviously a certain parallelism with the case of *Bryophyta*, where the sporogonium arising from the oospore is epiphytic and partially parasitic upon the female plant, and always culminates in the production of spores. Not even *Riccia*, with its rudimentary sporogonium, has so simple a corresponding stage as *Bangia*, for, while there is some amount of sterile tissue in *Riccia*, in *Bangia* the oospore completely divides to form carpospores. Excluding *Bangiaceæ*, however, from consideration, the *Eyflorideæ* present in the product of the development of the oospore like *Bryophyta* a structure partly sterile and partly fertile. There is, nevertheless, this important difference between the two cases. While the spore of *Bryophyta* on germination gives rise to the sexual plant, the carpospore of the Alga may give rise on germination to a plant bearing a second sort of asexual cells, viz., the tetraspores, and the sexual plant may only be reached after a series of such plants have been successively generated. It is possible, however, that the tetraspore formation should be regarded as comparable with the prolific vegetative reproduction of *Bryophyta*, and in favour of this view there is the fact that the tetraspores originate on the thallus in a different way from carpospores with which the spores of *Bryophyta* are in the first place to be compared; moreover, in certain *Nemalionales* the production of tetraspores does not occur, and the difficulty referred to does not arise in such cases. Altogether, it is difficult to resist the conclusion that *Florideæ* present in a modified form the same fundamental phenomenon of alternation of generations as prevails in the higher plants. Among *Phæophyceæ* it is well known that the oospore of *Fucaceæ* germinates directly into the sexual plant, and there is thus only one generation. Moreover, it is known that the reduction in the number of chromosomes which occurs at the initiation of the gametophyte generation in *Pteridophyta* occurs in the culminating stage of *Fucus*, where the oogonium is separated from the stalk-cell, so that, unless it be contended that the *Fucus* is really a sporophyte which does not produce spores, and that the gametophyte is represented merely by the oogonium and antheridium, there is no semblance of alternation of generation in this case. The only case among *Phæophyceæ* which has been considered to point to the existence of such a phenomenon is *Cutleria*. Here the asexual cells are borne upon the so-called *Aglaozonia reptans* and the sexual cells upon the plants known as *Cutleria*. The spores of the *Aglaozonia* form are known to give rise to sexual plants, and the oospore of *Cutleria* has been observed to grow into rudimentary *Aglaozonia*. It is probable, however, that there is nothing more here than strongly-contrasted growth-forms. Among *Chlorophyceæ*, it is often the case that the oospore on germination divides up directly to form a brood of zoospores. In *Coleochæte*, this seems to be preceded by the formation of a minute parenchymatous mass, in each cell of which a zoospore is produced. In *Sphæroplea*, it is only at this stage that zoospores are formed at all; but in most cases, such as *Ædogonium*, *Ulothrix*, *Coleochæte*, similar zoospores are produced again and again upon the thallus, and the product of the oospore may be regarded as merely a first brood of

a series. It has been held by some, however, that the first brood corresponds to the sporophyte generation of the higher plants, and that the rest of the cycle is the gametophyte generation. Were the case of *Sphæroplea* to stand alone, the phenomenon might perhaps be regarded as an alternation of generations, but still only comparable with the case of *Bangia*, and not the case of the *Florideæ*. But it is difficult to apply such a term at all to those cases in which there intervene between the oospore and the next sexual stage a series of generations, the zoospores of which are all precisely similar.

The difficulty of tracing the relationships of Algæ is largely due to the inadequacy of our knowledge of the conditions under which they pass through the critical stages of their life-cycle. Of the thousands of species which have been distinguished, ^{Poly-} morphisms. relatively few have been traced from spore to spore, as the flowering plants have been observed from seed to seed. The aquatic habit of most of the species and the minute size of many of them are difficulties which do not exist in the case of most seed-plants. From the analogy of the higher plants observers have justly argued that when they have seen and marked the characters of the reproductive organs they have found the plant at the stage when it exhibits its most noteworthy features, and they have named and classified the species in accordance with these observations. While even in such cases it is obvious that interesting stages in the life of the plant may escape notice altogether, in the cases of those plants the reproduction of which is unknown, and which have been named and placed on the analogy of the vegetative parts alone, there is considerable danger that a plant may be named as a distinct species which is only a stage in the life of another distinct and perhaps already known species. To take an example, *Lemanea* and *Batrachospermum* are *Florideæ* which bear densely-whorled branches, but which, on the germination of the carpospore, give rise to a laxly-filamentous, somewhat irregularly branched plant, from which the ordinary sexual plants arise at a later stage. This filamentous structure has been attributed to the genus *Chantransia*, which it greatly resembles, especially when, as is said to be the case in *Batrachospermum*, it bears similar monospores. The true *Chantransia*, however, bears its own sexual organs as well as monospores. To the specific identity of *Haplospora globosa* and *Scaphospora speciosa*, and of *Cutleria multifida* and *Aglaozonia reptans*, reference has already been made. Again, many Green Algæ—some unicellular, like *Sphærella* and *Chlamydomonas*; some colonial forms, like *Volvox* and *Hormotila*; some even filamentous forms, like *Ulothrix* and *Stigeoclonium*—are known to pass into a condition resembling that of a *Palmella*, and might escape identification on this account.

It is, on the other hand, a danger in the opposite sense to conclude that all *Chantransia* species are stages in the life-cycle of other plants, and, similarly, that all irregular colonial forms, like *Palmella*, represent phases in the life of other Green Algæ. Long ago, Kützing went so far as to express the belief that the lower Algæ were all capable of transformations into higher forms, even into moss-protonemata. Later writers have also thought that in all four groups of Algæ transformations of a most far-reaching character occur. Thus Borzi finds that *Protoderma viride* passes through a series of changes so varied that at different times it presents the characters of twelve different genera. Chodat does not find so general a polymorphism, but nevertheless holds that *Raphidium* passes through stages represented by *Protococcus*, *Characium*, *Dactylococcus*, and *Sciadium*. Klebs has, however, recently canvassed the conclusions of both these investi-

gators; and as the result of his own observations declares that Algæ, so far from being as polymorphic as they have been described, vary only within relatively narrow limits, and present on the whole as great fixity as the higher plants. It certainly supports his view to discover, on subjecting to a careful investigation *Botrydium granulatum*, a Siphonaceous Alga whose varied forms had been described by Rostafinski and Woronin, that these authors had included in the life-cycle, stages of a second Alga described previously by Kützing, and now described afresh by Klebs as *Protosiphon botryoides*. In *Botrydium* the chromatophores are small, without pyrenoids, and oil-drops are present; in *Protosiphon* the chromatophores form a network with pyrenoids, and the contents include starch. Klebs insists that the only solution of such problems is the subjection of the Algæ in question to a rigorous method of pure culture. It is interesting to learn that Senn, pursuing the methods described by Klebs, has confirmed Chodat's observation of the passage of *Raphidium* into a *Dactyloococcus*-stage, although he was unable to observe further metamorphosis. He has also seen *Pleurococcus viridis* dividing so as to form a filament, but has not succeeded in seeing the formation of zoospores as described by Chodat. While, therefore, there is much evidence of a negative character against the existence of an extensive polymorphism among Algæ, some amount of metamorphosis is known to occur. But until the conditions under which a particular transformation takes place have been ascertained and described, so that the observation may be repeated by other investigators, scant credence is likely to be given to the more extreme polymorphic views.

In comparison with the higher plants, Algæ exhibit so much simplicity of structure, while the conditions under which they grow are so much more readily controlled, that they have frequently been the subject of physiological investigation with a view chiefly to the application of the results to the study of the higher plants. (See PHYSIOLOGY OF PLANTS). In the literature of vegetable physiology there has thus accumulated a great body of facts relating not only to the phenomena of reproduction, but also to the nutrition of Algæ. With reference to their chemical physiology, the gelatinization of the cell-wall, which is so marked a feature, is doubtless attributable to the occurrence along with cellulose of pectic compounds. There is, however, considerable variation in the nature of the membrane in different species; thus the cell-wall of *Ædogonium*, treated with sulphuric acid and iodine, turns a bright blue, while the colour is very faint in the case of *Spirogyra*, the wall of which is said to consist for the most part of pectose. While starch occurs commonly as a cell-content in the majority of the Green Algæ no trace of it occurs in *Vaucheria* and some of its allies, nor is it known in the whole of the *Phæophyceæ* and *Rhodophyceæ*. In certain *Euphæophyceæ* bodies built up of concentric layers, and attached to the chromatophores, were described by Schmitz as phæophycean-starch; they do not, however, give the ordinary starch reaction. Other granules, easily mistaken for the "starch" granules, are also found in the cells of *Phæophyceæ*; these possess a power of movement apart from the protoplasm, and are considered to be vesicles and to contain phloro-glucin. The colourless granules of *Florideæ*, which are supposed to constitute the carbohydrate reserve material, have been called floridean-starch. A white efflorescence which appears on certain Brown Algæ (*Saccorhiza bulbosa*, *Laminaria saccharina*), when they are dried in the air, is found to consist of mannite. Mucin is known in the cell-sap of *Acetabularia*. Some *Siphonales* (*Codium*) give rise to proteid crystalloids,

and they are of constant occurrence among *Florideæ*. The presence of tannin has been established in the case of a great number of freshwater Algæ.

By virtue of the possession of chlorophyll all Algæ are capable of utilizing carbonic acid gas as a source of carbon in the presence of sunlight. The presence of phycoyanin, phycophæin, and phycoerythrin considerably modifies the absorption spectra for the plants in which they occur. Thus in the case of phycoerythrin the maximum absorption, apart from the great absorption at the blue end of the spectrum, is not, as in the case where chlorophyll occurs alone, near the Fraunhofer line B, but farther to the right beyond the line D. By an ingenious method devised by Engelmann, it may be shown that the greatest liberation of oxygen, and consequently the greatest assimilation of carbon, occurs in that region of the spectrum represented by the absorption bands. In this connexion Pfeffer points out that the penetrating power of light into a clear sea varies for light of different colours. Thus red light is reduced to such an extent as to be insufficient for growth at a depth of 34 metres, yellow light at a depth of 177 metres, and green light at 322 metres. It is thus an obvious advantage to Red Algæ, which flourish at considerable depths, to be able to utilize yellow light rather than the red, which is extinguished so much sooner. The experiment of Engelmann referred to deserves to be mentioned here, if only in illustration of the use to which Algæ have been put in the study of physiological problems. Engelmann observed that certain Bacteria were motile only in the presence of oxygen, and that they retained their motility in a microscopic preparation in the neighbourhood of an Algal filament when they had come to rest elsewhere on account of the exhaustion of oxygen. After the Bacteria had all been brought to rest by being placed in the dark, he threw a spectrum upon the filament, and observed in what region the Bacteria first regained their motility, owing to the liberation of oxygen in the process of carbon-assimilation. He found that these places corresponded closely with the region of the absorption band for the Algæ under experiment.

Although Algæ generally are able to use carbonic acid gas as a source of carbon, some Algæ, like certain of the higher plants, are capable of utilizing organic compounds for this purpose. Thus *Spirogyra* filaments, which have been denuded of starch by being placed in the dark, form starch in one day if they are placed in a 10 to 20 per cent. solution of dextrose. According to Bokorny, moreover, it appears that such filaments will yield starch from formaldehyde when they are supplied with sodium oxymethyl sulphate, a salt which readily decomposes into formaldehyde and hydrogen sodium sulphite, an observation which has been taken to mean that formaldehyde is always a stage in the synthesis of starch. With reference to the assimilation of nitrogen, it would seem that Algæ, like other green plants, can best use it when it is presented to them in the form of a nitrate. Some Algæ, however, seem to flourish better in the presence of organic compounds. In the case of *Scenedesmus acutus*, it is said that the Alga is unable to take up nitrogen in the form of a nitrate or ammoniacal salt, and requires some such substance as an amide or a peptone. On the other hand it has been held by Frank and other observers that atmospheric nitrogen is fixed by the agency of Green Algæ in the soil. (For the remarkable symbiotism between Algæ and Fungi, see FUNGI.)

Excepting where the thallus is impregnated with silica, as in *Diatomaceæ*, or carbonate of lime, as in *Corallinaceæ*, *Characeæ*, and some *Siphonales*, it is perhaps not surprising that Algæ should not have been extensively preserved in the fossil form. Considering, however, that it is gener-

Colouring-matters.

Physiology.

ally believed that *Bryophyta* and vascular plants are descended from an Algal ancestry, it is natural to suppose that, prior to the luxuriant vegetable growths of the Carboniferous period, there must have existed an age of Algæ. It was doubtless this expectation that has led to the description of a number of Silurian and Devonian remains as Algæ upon what is now regarded as inadequate evidence. The geologic record is, as perhaps is to be expected, exceedingly poor, except as regards the Calcareous Siphonales, which are well represented at various horizons, from the Silurian to the Tertiary; even the *Diatomaceæ*, which are found in great quantities in the Tertiary deposits, do not occur at all earlier than the chalk. It is believed, however, that the Devonian fossil, *Nematophycus*, is a Laminarian Alga, but it is not until the late Secondary and the Tertiary formations that fossil remains of Algæ become frequent. (See PALÆO-BOTANY.)

The subjoined list includes the larger standard works on Algæ, together with a number of papers to which reference is made in this article. For a detailed catalogue of Algological literature, see the "Bibliotheca Phycologica" in De Toni's *Sylloge Algarum*, vol. i. (1889), with the addendum thereto in vol. iv. (1897) of the same work.

Algarve, the southernmost province of Portugal, coinciding with the modern district of Faro, with an area of 1872 square miles and population 228,635—a density of 122 inhabitants to the square mile. The coast is fringed for a distance of 30 miles, from Quarteira to Tavira, with long sandy islands, through which there are six passages, the most important being the New Bar, between Faro and Olhão. In 1896 the fisheries yielded 61,132 tons of herring, valued at £79,100; in 1897, 76,845 tons, valued at £68,200; and in 1898, 65,637 tons, valued at £56,900. The sardines caught in the same years averaged £73,250 in value. The capital is Faro.

Algebra, Universal.—1. This term (employed by Sylvester in a rather more restricted sense) has come to be used to denote the comparative study of algebra in general, as distinguished from its applications, and from

the detailed exposition of any special variety of it. It is not easy to give a thoroughly satisfactory definition of algebra; for the purpose of this article "an algebra" will be taken to mean a mathematical calculus in which symbolical expressions of certain conventional types are constructed, and their relations investigated according to a fixed consistent system of formal rules of equivalence. This definition, imperfect as it is, will at least serve to indicate the essentially formal and abstract nature of algebraic reasoning. Whether a particular symbolism is to be regarded as an algebra or not depends partly upon its formal development, partly upon the sense attributed to the term "mathematical." Thus, for instance, the methods of symbolic logic have produced a calculus which is generally recognized to be an algebra, because it admits of a formal treatment which is independent of the particular meaning originally given to its symbols; while,

on the other hand, the "equations" of chemistry, although symbolical in form, are not deductions from a limited number of fundamental equivalences, and for this reason are not regarded as algebraical. It is conceivable that, in course of time, a new algebra may be invented, suggested by chemistry and admitting of a chemical interpretation, and in fact a certain analogy has been observed between the graphic symbols of organic chemistry and the umbral notation introduced by Aronhold into the theory of algebraic forms.

2. What will here be called "ordinary" algebra developed very gradually as a kind of shorthand, devised to abbreviate the discussion of arithmetical problems and the statement of arithmetical facts. Although the distinction is one which cannot be ultimately maintained, it is convenient to classify the signs of algebra into symbols of quantity (usually figures or letters), symbols of operation, such as $+$, $\sqrt{\quad}$, and symbols of distinction, such as brackets. Even when the formal evolution of the science was fairly complete, it was taken for granted that its symbols of quantity invariably stood for numbers, and that its symbols of operation were restricted to their ordinary arithmetical meanings. It could not escape notice that one and the same symbol, such as $\sqrt{(a-b)}$, or even $(a-b)$, sometimes did and sometimes did not admit of arithmetical interpretation, according to the values attributed to the letters involved. This led to a prolonged controversy on the nature of negative and imaginary quantities, which was ultimately settled in a very curious way. The progress of analytical geometry led to a geometrical interpretation both of negative and also of imaginary quantities; and when a "meaning," or, more properly, an interpretation, had thus been found for the symbols in question, a reconsideration of the old algebraic problem became inevitable, and the true solution, now so obvious, was eventually obtained. It was at last realized that the laws of algebra do not depend for their validity upon any particular interpretation, whether arithmetical, geometrical, or other; the only question is whether these laws do or do not involve any logical contradiction. When this fundamental truth had been fully grasped, mathematicians began to inquire whether algebras might not be discovered which obeyed laws different from those obtained by the generalization of arithmetic. The answer to this question has been so manifold as to be almost embarrassing. All that can be done here is to give a sketch of the more important and independent "special algebras" at present known to exist.

3. Although the results of ordinary algebra will be taken for granted, it is convenient to give the principal rules upon which it is based. They are

$$\begin{array}{l} (a+b)+c=a+(b+c) \quad (A) \quad (a \times b) \times c = a \times (b \times c) \quad (A') \\ a+b=b+a \quad (B) \quad a \times b = b \times a \quad (B') \\ a(b+c) = ab+ac \quad (D) \\ (a-b)+b=a \quad (I) \quad (a \div b) \times b = a \quad (I') \end{array}$$

These formulæ express the *associative* and *commutative* laws of the operations $+$ and \times , the *distributive* law of \times , and the definitions of the *inverse* symbols $-$ and \div , which are assumed to be unambiguous. The special symbols 0 and 1 are used to denote $a-a$ and $a \div a$. They behave exactly like the corresponding symbols in arithmetic; and it follows from this that whatever "meaning" is attached to the symbols of quantity, ordinary algebra includes arithmetic, or at least an image of it. Every ordinary algebraic quantity may be regarded as of the form $a + \beta \sqrt{-1}$, where a, β are "real"; that is to say, every algebraic equivalence remains valid when its symbols of quantity are interpreted as complex numbers of the type $a + \beta \sqrt{-1}$ (cf. NUMBER). But the symbols of ordinary algebra do not necessarily

denote numbers; they may, for instance, be interpreted as coplanar points or vectors. Evolution and involution are usually regarded as operations of ordinary algebra; this leads to a notation for powers and roots, and a theory of irrational algebraic quantities analogous to that of irrational numbers.

4. The only known type of algebra which does not contain arithmetical elements is substantially due to Boole. Although originally suggested by formal logic, it is most simply interpreted as an algebra of *Non-numerical algebra* regions in space. Let i denote a definite region of space; and let a, b , etc., stand for definite parts of i . Let $a+b$ denote the region made up of a and b together (the common part, if any, being reckoned only once), and let $a \times b$ or ab mean the region common to a and b . Then $a+a=aa=a$; hence numerical coefficients and indices are not required. The inverse symbols $-$, \div are ambiguous, and in fact are rarely used. Each symbol a is associated with its *supplement* \bar{a} which satisfies the equivalences $a+\bar{a}=i$, $a\bar{a}=0$, the latter of which means that a and \bar{a} have no region in common. Finally, there is a *law of absorption* expressed by $a+ab=a$. From every proposition in this algebra a reciprocal one may be deduced by interchanging $+$ and \times , and also the symbols 0 and i . For instance, $x+y=x+\bar{x}y$ and $xy=x(\bar{x}+y)$ are reciprocal. The operations $+$ and \times obey all the ordinary laws A, C, D (§ 3).

5. A point A in space may be associated with a (real, positive, or negative) numerical quantity a , called its *weight*, and denoted by the symbol aA . The sum of two weighted points $aA, \beta B$ is, by *Möbius's barycentric calculus*, definition, the point $(a+\beta)G$, where G divides AB so that $AG:GB=\beta:a$. It can be proved by geometry that

$$(aA + \beta B) + \gamma C = aA + (\beta B + \gamma C) = (a + \beta + \gamma)P,$$

where P is in fact the centroid of masses a, β, γ placed at A, B, C respectively. So, in general, if we put

$$aA + \beta B + \gamma C + \dots + \lambda L = (a + \beta + \gamma + \dots + \lambda)X.$$

X is, in general, a determinate point, the *barycentre* of $aA, \beta B$, etc. (or of A, B, etc. for the weights a, β , etc.). If $(a + \beta + \dots + \lambda)$ happens to be zero, X lies at infinity in a determinate direction; unless $-aA$ is the barycentre of $\beta B, \gamma C, \dots, \lambda L$, in which case $aA + \beta B + \dots + \lambda L$ vanishes identically, and X is indeterminate. If ABCD is a tetrahedron of reference, any point P in space is determined by an equation of the form

$$(a + \beta + \gamma + \delta)P = aA + \beta B + \gamma C + \delta D:$$

a, β, γ, δ are, in fact, equivalent to a set of homogeneous co-ordinates of P. For constructions in a fixed plane three points of reference are sufficient. It is remarkable that Möbius employs the symbols AB, ABC, ABCD in their ordinary geometrical sense as lengths, areas, and volumes, except that he distinguishes their sign; thus $AB = -BA$, $ABC = -ACB$, and so on. If he had happened to think of them as "products," he might have anticipated Grassmann's discovery of the extensive calculus. From a merely formal point of view, we have in the barycentric calculus a set of "special symbols of quantity" or "extraordinaries" A, B, C, etc., which combine with each other by means of operations $+$ and $-$ which obey the ordinary rules, and with ordinary algebraic quantities by operations \times and \div , also according to the ordinary rules, except that division by an extraordinary is not used.

6. A quaternion is best defined as a symbol of the type $q = \sum a_s e_s = a_0 e_0 + a_1 e_1 + a_2 e_2 + a_3 e_3$, where $e_0 \dots e_3$ are independent extraordinaries *quaternions* and $a_0 \dots a_3$ ordinary algebraic quantities, which may be called the co-ordinates of q . The sum and pro-

duct of two quaternions are defined by the formulæ

$$\begin{aligned} \sum a_s e_s + \sum \beta_s e_s &= \sum (a_s + \beta_s) e_s \\ \sum a_r e_r \times \sum \beta_s e_s &= \sum a_r \beta_s e_r e_s, \end{aligned}$$

where the products $e_r e_s$ are further reduced according to the following multiplication table, in which, for example,

	e_0	e_1	e_2	e_3
e_0	e_0	e_1	e_2	e_3
e_1	e_1	$-e_0$	e_3	$-e_2$
e_2	e_2	$-e_3$	$-e_0$	e_1
e_3	e_3	e_2	$-e_1$	$-e_0$

the second line is to be read $e_1 e_0 = e_1, e_1^2 = -e_0, e_1 e_2 = e_3, e_1 e_3 = -e_2$. The effect of these definitions is that the sum and the product of two quaternions are also quaternions; that addition is associative and commutative; and that multiplication is associative and distributive, but not commutative. Thus $e_1 e_2 = -e_2 e_1$, and if q, q' are any two quaternions, qq' is generally different from $q'q$. The symbol e_0 behaves exactly like 1 in ordinary algebra; Hamilton writes 1, i, j, k instead of e_0, e_1, e_2, e_3 , and in this notation all the special rules of operation may be summed up by the equalities

$$i^2 = j^2 = k^2 = ij = ji = -1.$$

Putting $q = a + \beta i + \gamma j + \delta k$, Hamilton calls a the *scalar part* of q , and denotes it by Sq ; he also writes Vq for $\beta i + \gamma j + \delta k$, which is called the *vector part* of q . Thus every quaternion may be written in the form $q = Sq + Vq$, where either Sq or Vq may separately vanish; so that ordinary algebraic quantities (or *scalars*, as we shall call them) and pure vectors may each be regarded as special cases of quaternions.

The equations $q' + x = q$ and $y + q' = q$ are satisfied by the same quaternion, which is denoted by $q - q'$. On the other hand, the equations $q'x = q$ and $yy' = q$ have, in general, different solutions. It is the value of y which is generally denoted by $q \div q'$; a special symbol for x is desirable, but has not been established. If we put $q'_0 = Sq' - Vq'$, then q'_0 is called the *conjugate* of q' , and the scalar $q'q'_0 = q'_0 q'$ is called the *norm* of q' and written Nq' . With this notation the values of x and y may be expressed in the forms—

$$x = q'_0 q / Nq', \quad y = qq'_0 / Nq',$$

which are free from ambiguity, since scalars are commutative with quaternions. The values of x and y are different, unless $V(qq'_0) = 0$.

In the applications of the calculus the co-ordinates of a quaternion are usually assumed to be numerical; when they are complex, the quaternion is further distinguished by Hamilton as a *biquaternion*. Clifford's biquaternions are quantities $\xi q + \eta r$, where q, r are quaternions, and ξ, η are symbols (commutative with quaternions) obeying the laws $\xi^2 = \xi, \eta^2 = \eta, \xi\eta = \eta\xi = 0$.

7. In the extensive calculus of the n th category, we have, first of all, n independent "units,"

Grassmann's extensive calculus.

e_1, e_2, \dots, e_n . From these are derived symbols of the type

$$A_1 = a_1 e_1 + a_2 e_2 + \dots + a_n e_n = \sum a e,$$

which we shall call *extensive quantities of the first species* (and, when necessary, of the n th category). The *co-ordinates* a_1, \dots, a_n are scalars, and in particular applications may be restricted to real or complex numerical values.

If $B_1 = \sum \beta e$, there is a law of addition expressed by

$$A_1 + B_1 = \sum (a_i + \beta_i) e_i = B_1 + A_1;$$

this law of addition is associative as well as commutative.

The inverse operation is free from ambiguity, and, in fact,

$$A_1 - B_1 = \sum (a_i - \beta_i) e_i.$$

To multiply A_1 by a scalar, we apply the rule

$$\xi A_1 = A_1 \xi = \sum (\xi a_i) e_i,$$

and similarly for division by a scalar.

All this is analogous to the corresponding formulæ in the barycentric calculus and in quaternions; it remains to consider the multiplication of two or more extensive quantities. The binary products of the units e_i are taken to satisfy the equalities

$$e_i^2 = 0, \quad e_i e_j = -e_j e_i;$$

this reduces them to $\frac{1}{2}n(n-1)$ distinct values, exclusive of zero. These values are assumed to be independent, so we have $\frac{1}{2}n(n-1)$ *derived units of the second species or order*. Associated with these new units there is a system of extensive quantities of the second species, represented by symbols of the type

$$A_2 = \sum a_i E_i^{(2)} \quad [i = 1, 2, \dots, \frac{1}{2}n(n-1)],$$

where $E_1^{(2)}, E_2^{(2)}$, etc., are the derived units of the second species. If $A_1 = \sum a_i e_i, B_1 = \sum \beta_i e_i$, the distributive law of multiplication is preserved by assuming

$$A_1 B_1 = \sum (a_i \beta_i) e_i e_i;$$

it follows that $A_1 B_1 = -B_1 A_1$, and that $A_1^2 = 0$.

By assuming the truth of the associative law of multiplication, and taking account of the reducing formulæ for binary products, we may construct derived units of the third, fourth... n th species. Every unit of the r th species which does not vanish is the product of r different units of the first species; two such units are independent unless they are permutations of the same set of primary units e_i , in which case they are equal or opposite according to the usual rule employed in determinants. Thus, for instance—

$$e_1 e_2 e_3 = e_1 e_2 e_3 = e_1 e_2 e_3 = -e_2 e_1 e_3 = e_2 e_3 e_1;$$

and, in general, the number of distinct units of the r th species in the n th category ($r \leq n$) is $C_{n,r}$. Finally, it is assumed that (in the n th category) $e_1 e_2 e_3 \dots e_n = 1$, the suffixes being in their natural order.

Let $A_r = \sum a E^{(r)}$ and $B_s = \sum \beta E^{(s)}$ be two extensive quantities of species r and s ; then if $r+s \leq n$, they may be multiplied by the rule

$$A_r B_s = \sum (a \beta) E^{(r)} E^{(s)}$$

where the products $E^{(r)} E^{(s)}$ may be expressed as derived units of species $(r+s)$. The product $B_s A_r$ is equal or opposite to $A_r B_s$, according as rs is even or odd. This process may be extended to the product of three or more factors such as $A_r B_s C_t \dots$ provided that $r+s+t+\dots$ does not exceed n . The law is associative; thus, for instance, $(AB)C = A(BC)$. But the commutative law does not always hold; thus, indicating species, as before, by suffixes, $A_r B_s C_t = (-1)^{rs+st+tr} C_t B_s A_r$, with analogous rules for other cases.

If $r+s > n$, a product such as $E_r E_s$, worked out by the previous rules, comes out to be zero. A characteristic feature of the calculus is that a meaning can be attached to a symbol of this kind by adopting a new rule, called that of *regressive multiplication*, as distinguished from the foregoing, which is *progressive*. The new rule requires some preliminary explanation. If E is any extensive unit, there is one other unit E' , and only one, such that the (progressive) product $EE' = 1$. This unit is called the supplement of E , and denoted by $|E$. For example, when $n = 4$,

$$|e_1 = e_2 e_3 e_4, \quad |e_2 = e_3 e_4 e_1, \quad |e_3 e_4 = -e_1,$$

and so on. Now when $r+s > n$, the product $E_r E_s$ is

defined to be that unit of which the supplement is the progressive product $|E_r|E_s$. For instance, if $n=4$, $E_r = e_1e_3$, $E_s = e_2e_3e_4$, we have

$$|E_r|E_s = (-e_2e_4)(-e_1) = e_1e_2e_4 = |e_3|,$$

consequently, by the rule of regressive multiplication,

$$e_1e_3e_2e_3e_4 = e_3.$$

Applying the distributive law, we obtain, when $r+s > n$,

$$A_rE_s = \sum \alpha E_r \sum \beta E_s = \sum (\alpha\beta) E_r E_s,$$

where the regressive products E_rE_s are to be reduced to units of species $(r+s-n)$ by the foregoing rule.

If $A = \sum \alpha E$, then, by definition, $|A| = \sum \alpha |E|$, and hence

$$A|(B+C) = A|B + A|C.$$

Now this is formally analogous to the distributive law of multiplication; and in fact we may look upon $A|B$ as a particular way of multiplying A and B (not A and $|B|$). The symbol $A|B$, from this point of view, is called the *inner* product of A and B , as distinguished from the *outer* product AB . An inner product may be either progressive or regressive. In the course of reducing such expressions as $(AB)C$, $(AB)\{C(DE)\}$ and the like, where a chain of multiplications has to be performed in a certain order, the multiplications may be all progressive, or all regressive, or partly one, partly the other. In the first two cases the product is said to be *pure*, in the third case *mixed*. A pure product is associative; a mixed product, speaking generally, is not.

The outer and inner products of two extensive quantities A, B , are in many ways analogous to the quaternion symbols Vab and Sab respectively. As in quaternions, so in the extensive calculus, there are numerous formulæ of transformation which enable us to deal with extensive quantities without expressing them in terms of the primary units. Only a few illustrations can be given here. Let a, b, c, d, e, f be quantities of the first species in the fourth category; $A, B, C \dots$ quantities of the third species in the same category. Then

$$(de)(abc) = (abde)c + (cade)b + (bcde)a \\ = (abce)d - (abcd)e,$$

$$(ab)(AB) = (aA)(bB) - (aB)(bA)$$

$$ab|c = (a|c)b - (b|c)a, \quad ab|cd = (a|c)(b|d) - (a|d)(b|c).$$

These may be compared and contrasted with such quaternion formulæ as

$$S(VabVcd) = SadSbc - SacSbd \\ dSabc = aSbcd - bScda + cSadb$$

where a, b, c, d denote arbitrary vectors.

8. An n -tuple linear algebra (also called a complex number-system) deals with quantities of the type $A = \sum \alpha_i e_i$ derived from n special units e_1, e_2, \dots, e_n . The sum and product of two quantities are defined in the first instance by the formulæ

$$\sum \alpha e + \sum \beta e = \sum (\alpha + \beta) e, \quad \sum \alpha_i e_i \times \sum \beta_j e_j = \sum (\alpha_i \beta_j) e_i e_j,$$

so that the laws A, C, D of § 3 are satisfied. The binary products $e_i e_j$, however, are expressible as linear functions of the units e_i by means of a "multiplication table" which defines the special characteristics of the algebra in question. Multiplication may or may not be commutative, and in the same way it may or may not be associative. The types of linear associative algebras, not assumed to be commutative, have been enumerated (with some omissions) up to sextuple algebras inclusive by B. Peirce. Quaternions afford an example of a quadruple algebra of this kind. If, in the extensive calculus of the n th category, all the units (including 1 and the derived units E) are taken to be homologous instead of being distributed into species, we may regard it as a $(2^n - 1)$ -tuple linear algebra, which, however, is not wholly associative. It

should be observed that while the use of special units, or extraordinary, in a linear algebra is convenient, especially in applications, it is not indispensable. Any linear quantity may be denoted by a symbol (a_1, a_2, \dots, a_n) in which only its scalar coefficients occur; in fact, the special units only serve, in the algebra proper, as *umbræ* or regulators of certain operations on scalars (see NUMBER, § 33). This idea finds fuller expression in the algebra of matrices, as to which it must suffice to say that a matrix is a symbol consisting of a rectangular array of scalars, and that matrices may be combined by a rule of addition which obeys the usual laws, and a rule of multiplication which is distributive and associative, but not, in general, commutative. Various special algebras (for example, quaternions) may be expressed in the notation of the algebra of matrices.

9. The algebras discussed up to this point may be considered as independent in the sense that each of them deals with a class of symbols of quantity more or less homogeneous, and a set of operations applying to them all. But when an algebra is used with a particular interpretation, or even in the course of its formal development, it frequently happens that new symbols of operation are, so to speak, superposed upon the algebra, and are found to obey certain formal laws of combination of their own. For instance, there are the symbols Δ, D, E used in the calculus of finite differences; Aronhold's symbolical method in the calculus of invariants; and the like. In most cases these subsidiary algebras, as they may be called, are inseparable from the applications in which they are used; but in any attempt at a natural classification of algebra (at present a hopeless task), they would have to be taken into account. Even in ordinary algebra the notation for powers and roots disturbs the symmetry of the rational theory; and when a schoolboy illegitimately extends the distributive law by writing $\sqrt{a+b} = \sqrt{a} + \sqrt{b}$, he is unconsciously emphasizing this want of complete harmony.

10. The reader cannot fail to observe that this article is far from being an outline of universal algebra, in the sense ascribed to that term at the beginning; it is, rather, a brief presentation of some of the principal facts with which universal algebra has to deal. It may even be doubted whether any theory of universal algebra, except in a very restricted or provisional sense, is actually possible at present. It may, perhaps, be admitted that we have arrived at the conception that an "algebraic quantity" is a symbol defined *merely* by its formal relations; and that the symbols $+$ and \times are legitimately used when the first is commutative and associative, and the second distributive. But there is hardly any other general statement that may not be upset by future discoveries; and in fact even these are inconsistent with much current notation. The state of mathematical symbolism to-day may be fairly compared to that of botany, when the idea of a natural classification first began to suggest itself.

STOLZ, *Vorlesungen über allgemeine Arithmetik*, ibid. 1868; A. N. WHITEHEAD, *A Treatise on Universal Algebra, with Applications*, vol. i. Cambridge, 1898 (a very comprehensive work, to which the writer of this article is in many ways indebted); and the *Encyclopædie d. math. Wissenschaften*, vol. i. Leipzig, 1898, &c. §§ A 1 (H. Schubert), A 4 (E. Study), and B 1 c (G. Landsberg). For the history of the development of ordinary algebra M. Cantor's *Vorlesungen über Geschichte der Mathematik* is the standard authority. (G. B. M.)

ALGEBRAIC FORMS.

THE subject-matter of algebraic forms is to a large extent connected with the linear transformation of algebraical polynomials which involve two or more variables. The theories of determinants and of symmetric functions and of the algebra of differential operations have an important bearing upon this comparatively new branch of mathematics. They are the chief instruments of research, and have themselves much benefited by being so employed. When a homogeneous polynomial is transformed by general linear substitutions as hereafter explained, and is then expressed in the original form with new coefficients affecting the new variables, certain functions of the new coefficients and variables are numerical multiples of the same functions of the original coefficients and variables. The investigation of the properties of these functions, as well for a single form as for a simultaneous set of forms, and as well for one as for many series of variables, is included in the theory of invariants. As far back as 1773 Lagrange, and later Gauss, had met with simple cases of such functions; Boole, in 1841 (*Camb. Math. Journ.* iii. pp. 1-20), made important steps, but it was not till 1845 that Cayley (*Coll. Math. Papers*, i. pp. 80-94, 95-112) showed by his calculus of hyper-determinants that an infinite series of such functions might be obtained systematically. The subject was carried on over a long series of years by himself, Sylvester, Salmon, Hesse, Aronhold, Hermite, Brioschi, Clebsch, Gordan, &c. The year 1868 saw a considerable enlargement of the field of operations. This arose from the study by Klein and Lie of a new theory of groups of substitutions; it was shown that there exists an invariant theory connected with every group of linear substitutions. The invariant theory then existing was classified by them as appertaining to "finite continuous groups." Other "Galois" groups were defined whose substitution coefficients have fixed numerical values, and are particularly associated with the theory of equations. Arithmetical groups, connected with the theory of quadratic forms and other branches of the theory of numbers, which are termed "discontinuous," and infinite groups connected with differential forms and equations, came into existence, and also particular linear and higher transformations connected with analysis and geometry. The effect of this was to co-ordinate many branches of mathematics and greatly to increase the number of workers. The subject of transformation in general has been treated by Sophus Lie in the classical work *Theorie der Transformationsgruppen*. The present article is merely concerned with algebraical linear transformation. Two methods of treatment have been carried on in parallel lines, the unsymbolic and the symbolic; both of these originated with Cayley, but he with Sylvester and the English school have in the main confined themselves to the former, whilst Aronhold, Clebsch, Gordan, and the Continental schools have principally restricted themselves to the latter. The two methods have been conducted so as to be in constant touch, though the nature of the results obtained by the

one differs much from those which flow naturally from the other. Each has been singularly successful in discovering new lines of advance and in encouraging the other to renewed efforts. Gordan first proved that for any system of forms there exists a finite number of covariants, in terms of which all others are expressible as rational and integral functions. This enabled Hilbert to produce a very simple unsymbolic proof of the same theorem. So the theory of the forms appertaining to a binary form of unrestricted order was first worked out by Cayley and MacMahon by unsymbolic methods, and later Stroh, from a knowledge of the results, was able to verify and extend the results by the symbolic method. At the moment of writing no English work exists on the symbolic methods, so that it has been judged proper to present to English readers a short *résumé* of those processes, and to refer them for other information to the existing English treatises. The partition method of treating symmetrical algebra is one which has been singularly successful in indicating new paths of advance in the theory of invariants; the important theorem of expressibility is, directly we exclude unity from the partitions, a theorem concerning the expressibility of covariants, and involves the theory of the reducible forms and of the syzygies. The theory brought forward has not yet found a place in any systematic treatise in any language, so that it has been judged proper to give a fairly complete account of it.

I. THE THEORY OF DETERMINANTS.

Let there be given n^2 quantities

$$\begin{matrix} a_{11} & a_{12} & a_{13} & \dots & a_{1n} \\ a_{21} & a_{22} & a_{23} & \dots & a_{2n} \\ a_{31} & a_{32} & a_{33} & \dots & a_{3n} \\ \dots & \dots & \dots & \dots & \dots \\ a_{n1} & a_{n2} & a_{n3} & \dots & a_{nn} \end{matrix}$$

and form from them a product of n quantities

$$a_{1\alpha} a_{2\beta} a_{3\gamma} \dots a_{n\nu}$$

Where the first suffixes are the natural numbers 1, 2, 3, ... n taken in order, and $\alpha, \beta, \gamma, \dots, \nu$ is some permutation of these n numbers. This permutation by a transposition of two numbers, say α, β , becomes $\beta, \alpha, \gamma, \dots, \nu$, and by successively transposing pairs of letters the permutation can be reduced to the form 1, 2, 3, ... n . Let k such transpositions be necessary; then the expression

$$\Sigma (-)^k a_{1\alpha} a_{2\beta} a_{3\gamma} \dots a_{n\nu}$$

the summation being for all permutations of the n numbers, is called the determinant of the n^2 quantities. The quantities $a_{1\alpha}, a_{2\beta} \dots$ are called the elements of the determinant; the term $(-)^k a_{1\alpha} a_{2\beta} a_{3\gamma} \dots a_{n\nu}$ is called n member of the determinant, and there are evidently $n!$ members corresponding to the $n!$ permutations of the n numbers 1, 2, 3, ... n . The determinant is usually written

$$\Delta = \begin{vmatrix} a_{11} & a_{12} & a_{13} & \dots & a_{1n} \\ a_{21} & a_{22} & a_{23} & \dots & a_{2n} \\ a_{31} & a_{32} & a_{33} & \dots & a_{3n} \\ \dots & \dots & \dots & \dots & \dots \\ a_{n1} & a_{n2} & a_{n3} & \dots & a_{nn} \end{vmatrix}$$

the square array being termed the *matrix* of the determinant. A matrix has in many parts of mathematics a signification apart from its evaluation as a determinant. A theory of matrices has been constructed by Cayley in connexion particularly with the

theory of linear transformation. The matrix consists of n rows and n columns. Each row as well as each column supplies one and only one element to each member of the determinant. Consideration of the definition of the determinant shows that the value is unaltered when the suffixes in each element are transposed.

Theorem.—If the determinant is transformed so as to read by columns as it formerly did by rows its value is unchanged. The leading member of the determinant is $a_{11}a_{22}a_{33} \dots a_{nn}$, and corresponds to the principal diagonal of the matrix.

We write frequently

$$\Delta = \Sigma \pm a_{11}a_{22}a_{33} \dots a_{nn} = (a_{11}a_{22}a_{33} \dots a_{nn}).$$

If the first two columns of the determinant be transposed the expression for the determinant becomes $\Sigma(-)^j a_{1\beta} a_{2\alpha} a_{3\gamma} \dots a_{nv}$, viz., α and β are transposed, and it is clear that the number of transpositions necessary to convert the permutation $\beta\alpha\gamma \dots \nu$ of the second suffixes to the natural order is changed by unity. Hence the transposition of columns merely changes the sign of the determinant. Similarly it is shown that the transposition of any two columns or of any two rows merely changes the sign of the determinant.

Theorem.—Interchange of any two rows or of any two columns merely changes the sign of the determinant.

Corollary.—If any two rows or any two columns of a determinant be identical the value of the determinant is zero.

Minors of a Determinant.—From the value of Δ we may separate those members which contain a particular element a_{ik} as a factor, and write the portion $a_{ik} A_{ik}$; A_{ik} , the cofactor of a_{ik} , is called a minor of order $n-1$ of the determinant.

Now $a_{11}A_{11} = \Sigma \pm a_{11}a_{22}a_{33} \dots a_{nn}$, wherein a_{11} is not to be changed, but the second suffixes in the product $a_{22}a_{33} \dots a_{nn}$ assume all permutations, the number of transpositions necessary determining the sign to be affixed to the member.

Hence $a_{11}A_{11} = a_{11} \Sigma \pm a_{22}a_{33} \dots a_{nn}$, where the cofactor of a_{11} is clearly the determinant obtained by erasing the first row and the first column.

$$\text{Hence } A_{11} = \begin{vmatrix} a_{22} & a_{33} & \dots & a_{nn} \\ a_{32} & a_{33} & \dots & a_{3n} \\ \dots & \dots & \dots & \dots \\ a_{n2} & a_{n3} & \dots & a_{nn} \end{vmatrix}$$

Similarly A_{ik} , the cofactor of a_{ik} , is shown to be the product of $(-)^{i+k}$ and the determinant obtained by erasing from Δ the i^{th} row and k^{th} column. No member of a determinant can involve more than one element from the first row. Hence we have the development

$$\Delta = a_{11}A_{11} + a_{12}A_{12} + a_{13}A_{13} + \dots + a_{1n}A_{1n},$$

proceeding according to the elements of the first row and the corresponding minors.

Similarly we have a development proceeding according to the elements contained in any row or in any column, viz.,

$$\Delta = a_{11}A_{11} + a_{12}A_{12} + a_{13}A_{13} + \dots + a_{1n}A_{1n} \quad \left. \vphantom{\Delta} \right\} (A).$$

$$\Delta = a_{1k}A_{1k} + a_{2k}A_{2k} + a_{3k}A_{3k} + \dots + a_{nk}A_{nk}$$

This theory enables the evaluation of a determinant by successive reduction of the orders of the determinants involved.

Ex. gr. $\begin{vmatrix} 1 & 0 & 3 \\ 2 & 1 & 6 \\ 0 & -5 & 3 \end{vmatrix} = 1 \begin{vmatrix} 1 & 6 \\ -5 & 3 \end{vmatrix} - 0 \begin{vmatrix} 2 & 6 \\ 0 & -3 \end{vmatrix} + 3 \begin{vmatrix} 2 & 1 \\ 0 & -5 \end{vmatrix}$
 $= 1 | 3 | -6 | -5 | + 3.2 | -5 | -3.1 | 0 |$
 $= 3 + 30 - 30 - 0 = 3.$

Since the determinant

$$\begin{vmatrix} a_{21} & a_{22} & a_{23} & \dots & a_{2n} \\ a_{31} & a_{32} & a_{33} & \dots & a_{3n} \\ a_{41} & a_{42} & a_{43} & \dots & a_{4n} \\ \dots & \dots & \dots & \dots & \dots \\ a_{n1} & a_{n2} & a_{n3} & \dots & a_{nn} \end{vmatrix}, \text{ having two identical rows,}$$

vanishes identically; we have by development according to the elements of the first row

$$a_{21}A_{11} + a_{22}A_{12} + a_{23}A_{13} + \dots + a_{2n}A_{1n} = 0;$$

and, in general, since

$$a_{i1}A_{i1} + a_{i2}A_{i2} + a_{i3}A_{i3} + \dots + a_{in}A_{in} = \Delta,$$

if we suppose the i^{th} and k^{th} rows identical

$$a_{k1}A_{i1} + a_{k2}A_{i2} + a_{k3}A_{i3} + \dots + a_{kn}A_{in} = 0 \quad (k \geq i);$$

and proceeding by columns instead of rows,

$$a_{1k}A_{1k} + a_{2k}A_{2k} + a_{3k}A_{3k} + \dots + a_{nk}A_{nk} = 0 \quad (k \geq i)$$

identical relations always satisfied by these minors.

If in the first relation of (A) we write $a_{is} = b_{is} + c_{is} + d_{is} + \dots$ we find that $\Sigma a_{is}A_{is} = \Sigma b_{is}A_{is} + \Sigma c_{is}A_{is} + \Sigma d_{is}A_{is} + \dots$ so that Δ breaks up into a sum of determinants, and we also obtain a theorem for the addition of determinants which have $n-1$ rows in common. If we multiply the elements of the second row by an arbitrary magnitude λ , and add to the corresponding elements of the first row, Δ becomes $\Sigma a_{1s}A_{1s} + \lambda \Sigma a_{2s}A_{1s} = \Sigma a_{1s}A_{1s} = \Delta$, showing that the

value of the determinant is unchanged. In general we can prove in the same way the—

Theorem.—The value of a determinant is unchanged if we add to the elements of any row or column the corresponding elements of the other rows or other columns respectively each multiplied by an arbitrary magnitude, such magnitude remaining constant in respect of the elements in a particular row or a particular column.

Observation.—Every factor common to all the elements of a row or of a column is obviously a factor of the determinant, and may be taken outside the determinant brackets.

Ex. gr. $\begin{vmatrix} a^2 & \beta^2 & \gamma^2 \\ a & \beta & \gamma \\ 1 & 1 & 1 \end{vmatrix} = \begin{vmatrix} a^2 & \beta^2 - a^2 & \gamma^2 - a^2 \\ a & \beta - a & \gamma - a \\ 1 & 0 & 0 \end{vmatrix} = \begin{vmatrix} \beta^2 - a^2 & \gamma^2 - a^2 \\ \beta - a & \gamma - a \end{vmatrix}$
 $= (\beta - a)(\gamma - a) \begin{vmatrix} \beta + a & \gamma + a \\ 1 & 1 \end{vmatrix} = (\beta - \gamma)(\gamma - a) \begin{vmatrix} \beta - \gamma & \gamma + a \\ 0 & 1 \end{vmatrix}$
 $= (\beta - a)(\gamma - a)(\beta - \gamma).$

The minor A_{ik} is $\frac{\partial \Delta}{\partial a_{ik}}$, and is itself a determinant of order $n-1$.

We may therefore differentiate again in regard to any element a_{rs} where $r \geq i, s \geq k$; we will thus obtain a minor of A_{ik} , which is a minor also of Δ of order $n-2$. It will be $A_{ik} = \frac{\partial A_{ik}}{\partial a_{rs}} = \frac{\partial^2 \Delta}{\partial a_{ik} \partial a_{rs}}$

and will be obtained by erasing from the determinant A_{ik} the row and column containing the element a_{rs} ; this was originally the r^{th} row and s^{th} column of Δ ; the r^{th} row of Δ is the r^{th} or $(r-1)^{\text{th}}$ row of A_{ik} according as $r \leq i$ and the s^{th} column of Δ is the s^{th} or $s-1^{\text{th}}$ column of A_{ik} according as $s \geq k$. Hence, if T_{rs} denote the number of transpositions necessary to bring the succession rs into ascending order of magnitude, the sign to be attached to the determinant arrived at by erasing the i^{th} and k^{th} rows and the k^{th} and s^{th} columns from Δ in order produce A_{ik} will be -1 raised to the power of $T_{rs} + T_{ks} + i + k + r + s$.

Similarly proceeding to the minors of order $n-3$, we find that

$$A_{ik} = \frac{\partial}{\partial a_{tu}} A_{ik} = \frac{\partial^2}{\partial a_{rs} \partial a_{tu}} A_{ik} = \frac{\partial^3 \Delta}{\partial a_{ik} \partial a_{rs} \partial a_{tu}}$$

Δ is obtained from Δ by erasing the $i^{\text{th}}, r^{\text{th}}, t^{\text{th}}$ rows, the $k^{\text{th}}, s^{\text{th}}, u^{\text{th}}$ columns, and multiplying the resulting determinant by -1 raised to the power $T_{rs} + T_{ks} + i + k + r + s + t + u$ and the general law is clear.

Corresponding Minors.—In obtaining the minor A_{ik} in the form of a determinant we erased certain rows and columns, and we would have erased in an exactly similar manner had we been forming the determinant associated with A_{ik} , since the deleting

lines intersect in two pairs of points. In the latter case the sign is determined by -1 raised to the same power as before, with the exception that T_{uks} replaces T_{uks} ; but if one of these numbers be even the other must be uneven; hence

$$A_{ik} = -A_{rk}$$

Moreover

$$a_{ik}a_{rs}A_{ik} + a_{is}a_{rk}A_{is} = \begin{vmatrix} a_{ik} & a_{is} \\ a_{rk} & a_{rs} \end{vmatrix} A_{ik},$$

where the determinant factor is given by the four points in which the deleting lines intersect. This determinant and that associated with A_{ik} are termed corresponding determinants. Similarly p lines of deletion intersecting in p^2 points yield corresponding determinants of orders p and $n-p$ respectively. Recalling the formula

$$\Delta = a_{11}A_{11} + a_{12}A_{12} + a_{13}A_{13} + \dots + a_{1n}A_{1n}$$

it will be seen that a_{1k} and A_{1k} involve corresponding determinants. Since A_{1k} is a determinant we similarly obtain

$$A_{1k} = a_{21}A_{2k} + \dots + a_{2,k-1}A_{2,k-1} + a_{2,k+1}A_{2,k+1} + \dots + a_{2n}A_{2n}$$

and thence

$$\Delta = \Sigma a_{1i}a_{2k}A_{2k} \text{ where } i \geq k;$$

and as before

$$\Delta = \Sigma \begin{vmatrix} a_{1i} & a_{2i} \\ a_{1k} & a_{2k} \end{vmatrix} A_{2k} \quad i > k,$$

an important expansion of Δ .

Similarly

$$\Delta = \Sigma \begin{vmatrix} a_{1i} & a_{2i} & a_{3i} \\ a_{1k} & a_{2k} & a_{3k} \\ a_{1r} & a_{2r} & a_{3r} \end{vmatrix} A_{3k} \quad i > k > r,$$

and the general theorem is manifest, and yields a development in a sum of products of corresponding determinants. If the j^{th}

column be identical with the i^{th} the determinant Δ vanishes identically; hence if j be not equal to $i, k,$ or $r,$

$$0 = \Sigma \begin{vmatrix} a_{1j} & a_{2j} & a_{3j} \\ a_{1k} & a_{2k} & a_{3k} \\ a_{1r} & a_{2r} & a_{3r} \end{vmatrix} \begin{matrix} A_{1i} \\ A_{2i} \\ A_{3i} \end{matrix}$$

Similarly, by putting one or more of the deleted rows or columns equal to rows or columns which are not deleted, we obtain, with Laplace, a number of identities between products of determinants of complementary orders.

Multiplication.—From the theorem given above for the expansion of a determinant as a sum of products of pairs of corresponding determinants it will be plain that the product of $\Delta = (a_{11}, a_{22}, \dots, a_{nn})$ and $D = (b_{11}, b_{22}, \dots, b_{nn})$ may be written as a determinant of order $2n,$ viz.—

$$\begin{vmatrix} a_{11} & a_{21} & a_{31} & \dots & a_{n1} & -1 & 0 & 0 & \dots & 0 \\ a_{12} & a_{22} & a_{32} & \dots & a_{n2} & 0 & -1 & 0 & \dots & 0 \\ a_{13} & a_{23} & a_{33} & \dots & a_{n3} & 0 & 0 & -1 & \dots & 0 \\ \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots \\ a_{1n} & a_{2n} & a_{3n} & \dots & a_{nn} & 0 & 0 & 0 & \dots & -1 \\ 0 & 0 & 0 & \dots & 0 & b_{11} & b_{12} & b_{13} & \dots & b_{1n} \\ 0 & 0 & 0 & \dots & 0 & b_{21} & b_{22} & b_{23} & \dots & b_{2n} \\ 0 & 0 & 0 & \dots & 0 & b_{31} & b_{32} & b_{33} & \dots & b_{3n} \\ \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & 0 & \dots & 0 & b_{n1} & b_{n2} & b_{n3} & \dots & b_{nn} \end{vmatrix} = \begin{vmatrix} A & B \\ C & D \end{vmatrix} \text{ for brevity.}$$

Multiply the $1^{\text{st}}, 2^{\text{nd}}, \dots, n^{\text{th}}$ rows by $b_{11}, b_{12}, \dots, b_{1n}$ respectively, and add to the $n+1^{\text{th}}$ row; by $b_{21}, b_{22}, \dots, b_{2n},$ and add to the $n+2^{\text{th}}$ row; by $b_{31}, b_{32}, \dots, b_{3n}$ and add to the $n+3^{\text{rd}}$ row, &c. C then becomes

$$\begin{vmatrix} a_{11}b_{11} + a_{12}b_{12} + \dots + a_{1n}b_{1n} & a_{21}b_{11} + a_{22}b_{12} + \dots + a_{2n}b_{1n} & \dots & a_{n1}b_{11} + a_{n2}b_{12} + \dots + a_{nn}b_{1n} \\ a_{11}b_{21} + a_{12}b_{22} + \dots + a_{1n}b_{2n} & a_{21}b_{21} + a_{22}b_{22} + \dots + a_{2n}b_{2n} & \dots & a_{n1}b_{21} + a_{n2}b_{22} + \dots + a_{nn}b_{2n} \\ a_{11}b_{31} + a_{12}b_{32} + \dots + a_{1n}b_{3n} & a_{21}b_{31} + a_{22}b_{32} + \dots + a_{2n}b_{3n} & \dots & a_{n1}b_{31} + a_{n2}b_{32} + \dots + a_{nn}b_{3n} \\ \dots & \dots & \dots & \dots \\ a_{11}b_{n1} + a_{12}b_{n2} + \dots + a_{1n}b_{nn} & a_{21}b_{n1} + a_{22}b_{n2} + \dots + a_{2n}b_{nn} & \dots & a_{n1}b_{n1} + a_{n2}b_{n2} + \dots + a_{nn}b_{nn} \end{vmatrix}$$

and all the elements of D become zero. Now by the expansion theorem the determinant becomes

$$(-1)^{1+2+3+\dots+n} B \cdot C = (-1)^{n(n+1)/2} B \cdot C.$$

We thus obtain for the product a determinant of order $n.$ We may say that, in the resulting determinant, the element in the i^{th} row and k^{th} column is obtained by multiplying the elements in the k^{th} row of the first determinant severally by the elements in the i^{th} row of the second, and has the expression

$$a_{k1}b_{i1} + a_{k2}b_{i2} + a_{k3}b_{i3} \dots + a_{kn}b_{in},$$

and we obtain other expressions by transforming either or both determinants so as to read by columns as they formerly did by rows.

Remark.—In particular the square of a determinant is a determinant of the same order $(b_{11}b_{22}b_{33} \dots b_{nn})$ such that $b_{kk} = b_{kk};$ it is for this reason termed symmetric.

The **Adjoint or Reciprocal Determinant** arises from $\Delta = (a_{11}a_{22}a_{33} \dots a_{nn})$ by substituting for each element a_{ik} the corresponding minor A_{ik} so as to form $D = (A_{11}A_{22}A_{33} \dots A_{nn}).$ If we form the product $\Delta \cdot D$ by the theorem for the multiplication of determinants we find that the element in the i^{th} row and k^{th} column of the product is

$$a_{k1}A_{i1} + a_{k2}A_{i2} + \dots + a_{kn}A_{in},$$

the value of which is zero when k is different from $i,$ whilst it has the value Δ when $k=i.$ Hence the product determinant has the principal diagonal elements each equal to Δ and the remaining elements zero. Its value is therefore Δ^n and we have the identity

$$D \cdot \Delta = \Delta^n \text{ or } D = \Delta^{n-1}.$$

It can now be proved that the first minor of the adjoint determinant, say $B_{11},$ is equal to $\Delta^{n-2}a_{11}.$

From the equations

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + a_{13}x_3 + \dots &= \xi_1, \\ a_{21}x_1 + a_{22}x_2 + a_{23}x_3 + \dots &= \xi_2, \\ a_{31}x_1 + a_{32}x_2 + a_{33}x_3 + \dots &= \xi_3, \\ \dots & \dots \end{aligned}$$

we derive

$$\begin{aligned} \Delta x_1 &= A_{11}\xi_1 + A_{21}\xi_2 + A_{31}\xi_3 + \dots, \\ \Delta x_2 &= A_{12}\xi_1 + A_{22}\xi_2 + A_{32}\xi_3 + \dots, \\ \Delta x_3 &= A_{13}\xi_1 + A_{23}\xi_2 + A_{33}\xi_3 + \dots, \end{aligned}$$

and thence

$$\begin{aligned} \Delta^{n-1}\xi_1 &= B_{11}\Delta x_1 + B_{12}\Delta x_2 + B_{13}\Delta x_3 + \dots, \\ \Delta^{n-1}\xi_2 &= B_{21}\Delta x_1 + B_{22}\Delta x_2 + B_{23}\Delta x_3 + \dots, \\ \Delta^{n-1}\xi_3 &= B_{31}\Delta x_1 + B_{32}\Delta x_2 + B_{33}\Delta x_3 + \dots, \end{aligned}$$

and comparison of the first and third systems yields

$$B_{11} = \Delta^{n-2}a_{11}.$$

In general it can be proved that any minor of order p of the adjoint is equal to the complementary of the corresponding minor of the original multiplied by the $p-1^{\text{th}}$ power of the original determinant.

Theorem.—The adjoint determinant is the $n-1^{\text{th}}$ power of the original determinant. The adjoint determinant will be seen subsequently to present itself in the theory of linear equations and in the theory of linear transformation.

Determinants of Special Forms.—It was observed above that the square of a determinant when expressed as a determinant of the same order is such that its elements have the property expressed by $a_{ik} = a_{ki}.$ Such determinants are called *symmetrical.* It is easy to see that the adjoint determinant is also symmetrical, viz., such that $A_{ik} = A_{ki},$ for the determinant got by suppressing the i^{th} row and k^{th} column differs only by an interchange of rows and columns from that got by suppressing the k^{th} row and i^{th} column. If any symmetrical determinant vanish and be bordered as shown below

$$\begin{vmatrix} a_{11} & a_{12} & a_{13} & \lambda_1 \\ a_{12} & a_{22} & a_{23} & \lambda_2 \\ a_{13} & a_{23} & a_{33} & \lambda_3 \\ \lambda_1 & \lambda_2 & \lambda_3 & . \end{vmatrix}$$

it is a perfect square when considered as a function of $\lambda_1, \lambda_2, \lambda_3.$ For since $A_{11}A_{22} - A_{12}^2 = \Delta a_{33},$ with similar relations, we have a number of relations similar to $A_{11}A_{22} = A_{12}^2,$ and either $A_{rr} = +\sqrt{(A_{rr}A_{ss})}$ or $-\sqrt{(A_{rr}A_{ss})}$ for all different values of r and $s.$ Now the determinant has the value

$$\begin{aligned} & -\{\lambda_1^2 A_{11} + \lambda_2^2 A_{22} + \lambda_3^2 A_{33} + 2\lambda_2 \lambda_3 A_{23} + 2\lambda_3 \lambda_1 A_{31} + 2\lambda_1 \lambda_2 A_{12}\} \\ & = -\Sigma \lambda_r^2 A_{rr} - 2\Sigma \lambda_r \lambda_s A_{rs} \text{ in general, and hence by substitution} \\ & \quad \pm \{\lambda_1 \sqrt{A_{11}} + \lambda_2 \sqrt{A_{22}} + \dots + \lambda_n \sqrt{A_{nn}}\}^2. \end{aligned}$$

A *skew symmetric determinant* has $a_{rr} = 0$ and $a_{rs} = -a_{sr}$ for all values of r and $s.$ Such a determinant when of uneven degree vanishes, for if we multiply each row by -1 we multiply the determinant by $(-1)^n = -1,$ and the effect of this is otherwise merely to transpose the determinant, so that it reads by rows as it formerly did by columns, an operation which we know leaves the determinant unaltered. Hence $\Delta = -\Delta$ or $\Delta = 0.$ When a skew symmetric determinant is of even degree it is a perfect square. This theorem is due to Cayley, and reference may be made to Salmon's *Higher Algebra,* 4th ed. Art. 39. In the case of the determinant of order 4 the square root is

$$A_{12}A_{34} - A_{13}A_{24} + A_{14}A_{23}.$$

A *skew determinant* is one which is skew symmetric in all respects, except that the elements of the leading diagonal are not all zero. Such a determinant is of importance in the theory of orthogonal substitution. In the theory of surfaces we transform from one set of three rectangular axes to another by the substitutions

$$\begin{aligned} X &= ax + by + cz, \\ Y &= a'x + b'y + c'z, \\ Z &= a''x + b''y + c''z, \end{aligned}$$

where $X^2 + Y^2 + Z^2 = x^2 + y^2 + z^2.$ This relation implies six equations between the coefficients, so that only three of them are independent. Further we find

$$\begin{aligned} x &= aX + a'Y + a''Z, \\ y &= bX + b'Y + b''Z, \\ z &= cX + c'Y + c''Z, \end{aligned}$$

and the problem is to express the nine coefficients in terms of three independent quantities.

In general in space of n dimensions we have n substitutions similar to

$$X_1 = a_{11}x_1 + a_{12}x_2 + \dots + a_{1n}x_n,$$

and we have to express the n^2 coefficients in terms of $\frac{1}{2}n(n-1),$ independent quantities; which must be possible, because

$$X_1^2 + X_2^2 + \dots + X_n^2 = x_1^2 + x_2^2 + x_3^2 + \dots + x_n^2.$$

Let there be $2n$ equations

$$\begin{aligned} x_1 &= b_{11}\xi_1 + b_{12}\xi_2 + b_{13}\xi_3 + \dots, \\ x_2 &= b_{21}\xi_1 + b_{22}\xi_2 + b_{23}\xi_3 + \dots, \\ \dots & \dots \\ X_1 &= b_{11}\xi_1 + b_{21}\xi_2 + b_{31}\xi_3 + \dots, \\ X_2 &= b_{12}\xi_1 + b_{22}\xi_2 + b_{32}\xi_3 + \dots, \\ \dots & \dots \end{aligned}$$

where $b_{rr} = 1$ and $b_{rs} = -b_{sr}$ for all values of r and $s.$ There are then $\frac{1}{2}n(n-1)$ quantities $b_{rs}.$ Let the determinant of the b 's be Δ_b and B_{rs} the minor corresponding to $b_{rs}.$ We can eliminate the quantities $\xi_1, \xi_2, \dots, \xi_n$ and obtain n relations

$$\begin{aligned} \Delta_b X_1 &= (2B_{11} - \Delta_b)x_1 + 2B_{21}x_2 + 2B_{31}x_3 + \dots, \\ \Delta_b X_2 &= 2B_{12}x_1 + (2B_{22} - \Delta_b)x_2 + 2B_{32}x_3 + \dots, \end{aligned}$$

and from these another equivalent set

$$\begin{aligned} \Delta_b x_1 &= (2B_{11} - \Delta_b)X_1 + 2B_{12}X_2 + 2B_{13}X_3 + \dots \\ \Delta_b x_2 &= 2B_{21}X_1 + (2B_{22} - \Delta_b)X_2 + 2B_{23}X_3 + \dots \end{aligned}$$

and now writing

$$\frac{2B_{ii} - \Delta_b}{\Delta_b} = a_{ii}, \quad \frac{2B_{ik}}{\Delta_b} = a_{ik},$$

we have a transformation which is orthogonal, because $\Sigma X^2 = \Sigma x^2$ and the elements a_{ik} , a_{ik} are functions of the $\frac{1}{2}n(n-1)$ independent quantities b . We may therefore form an orthogonal transformation in association with every skew determinant which has its leading diagonal elements unity, for the $\frac{1}{2}n(n-1)$ quantities b are clearly arbitrary.

For the second order we may take

$$\Delta_b = \begin{vmatrix} 1, \lambda \\ -\lambda, 1 \end{vmatrix} = 1 + \lambda^2,$$

and the adjoint determinant is the same; hence

$$\begin{aligned} (1 + \lambda^2)x_1 &= (1 - \lambda^2)X_1 + 2\lambda X_2 \\ (1 + \lambda^2)x_2 &= -2\lambda X_1 + (1 - \lambda^2)X_2. \end{aligned}$$

Similarly, for the order 3, we take

$$\Delta_b = \begin{vmatrix} 1 & \nu - \mu & \\ -\nu & 1 & \lambda \\ \mu - \lambda & & 1 \end{vmatrix} = 1 + \lambda^2 + \mu^2 + \nu^2,$$

and the adjoint is

$$\begin{vmatrix} 1 + \lambda^2 & \nu + \lambda\mu & -\mu + \lambda\nu \\ -\nu + \lambda\mu & 1 + \mu^2 & \lambda + \mu\nu \\ \mu + \lambda\nu & -\lambda + \mu\nu & 1 + \nu^2 \end{vmatrix},$$

leading to the orthogonal substitution

$$\begin{aligned} \Delta_b x_1 &= (1 + \lambda^2 - \mu^2 - \nu^2)X_1 + 2(\nu + \lambda\mu)X_2 + 2(-\mu + \lambda\nu)X_3 \\ \Delta_b x_2 &= 2(\lambda\mu - \nu)X_1 + (1 + \mu^2 - \lambda^2 - \nu^2)X_2 + 2(\mu\nu + \lambda)X_3 \\ \Delta_b x_3 &= 2(\lambda\nu + \mu)X_1 + 2(\mu\nu - \lambda)X_2 + (1 + \nu^2 - \lambda^2 - \mu^2)X_3. \end{aligned}$$

Functional determinants were first investigated by Jacobi in a work *De Determinantibus Functionalibus*. Suppose n dependent variables y_1, y_2, \dots, y_n , each of which is a function of n independent variables x_1, x_2, \dots, x_n , so that $y_i = f_i(x_1, x_2, \dots, x_n)$. From the differential coefficients of the y 's with regard to the x 's we form the functional determinant

$$R = \begin{vmatrix} \frac{\partial y_1}{\partial x_1} & \frac{\partial y_1}{\partial x_2} & \dots & \frac{\partial y_1}{\partial x_n} \\ \frac{\partial y_2}{\partial x_1} & \frac{\partial y_2}{\partial x_2} & \dots & \frac{\partial y_2}{\partial x_n} \\ \dots & \dots & \dots & \dots \\ \frac{\partial y_n}{\partial x_1} & \frac{\partial y_n}{\partial x_2} & \dots & \frac{\partial y_n}{\partial x_n} \end{vmatrix} = \begin{pmatrix} y_1, y_2, \dots, y_n \\ x_1, x_2, \dots, x_n \end{pmatrix} \text{ for brevity.}$$

If we have new variables z such that $z_i = \phi_i(y_1, y_2, \dots, y_n)$, we have also $z_i = \psi_i(x_1, x_2, \dots, x_n)$, and we may consider the three determinants

$$\begin{pmatrix} y_1, y_2, \dots, y_n \\ x_1, x_2, \dots, x_n \end{pmatrix}, \begin{pmatrix} z_1, z_2, \dots, z_n \\ y_1, y_2, \dots, y_n \end{pmatrix}, \begin{pmatrix} z_1, z_2, \dots, z_n \\ x_1, x_2, \dots, x_n \end{pmatrix}.$$

Forming the product of the first two by the product theorem, we obtain for the element in the i^{th} row and k^{th} column

$$\frac{\partial z_i}{\partial y_1} \frac{\partial y_1}{\partial x_k} + \frac{\partial z_i}{\partial y_2} \frac{\partial y_2}{\partial x_k} + \dots + \frac{\partial z_i}{\partial y_n} \frac{\partial y_n}{\partial x_k}$$

which is $\frac{\partial z_i}{\partial x_k}$, the partial differential coefficient of z_i with regard to x_k . Hence the product theorem

$$\begin{pmatrix} z_1, z_2, \dots, z_n \\ y_1, y_2, \dots, y_n \end{pmatrix} \begin{pmatrix} y_1, y_2, \dots, y_n \\ x_1, x_2, \dots, x_n \end{pmatrix} = \begin{pmatrix} z_1, z_2, \dots, z_n \\ x_1, x_2, \dots, x_n \end{pmatrix};$$

and as a particular case

$$\begin{pmatrix} y_1, y_2, \dots, y_n \\ x_1, x_2, \dots, x_n \end{pmatrix} \begin{pmatrix} x_1, x_2, \dots, x_n \\ y_1, y_2, \dots, y_n \end{pmatrix} = 1.$$

Theorem.—If the functions y_1, y_2, \dots, y_n be not independent of one another the functional determinant vanishes, and conversely if the determinant vanishes, y_1, y_2, \dots, y_n are not independent functions of x_1, x_2, \dots, x_n .

Linear Equations.—It is of importance to study the application of the theory of determinants to the solution of a system of linear equations. Suppose given the n equations

$$\begin{aligned} f_1 &= a_{11}x_1 + a_{12}x_2 + \dots + a_{1n}x_n = 0, \\ f_2 &= a_{21}x_1 + a_{22}x_2 + \dots + a_{2n}x_n = 0, \\ &\dots \\ f_n &= a_{n1}x_1 + a_{n2}x_2 + \dots + a_{nn}x_n = 0. \end{aligned}$$

Denote by Δ the determinant $(a_{11}a_{22}\dots a_{nn})$.

Multiplying the equations by the minors $A_{1\mu}, A_{2\mu}, \dots, A_{n\mu}$ respectively, and adding, we obtain

$$x_\mu (a_{1\mu}A_{1\mu} + a_{2\mu}A_{2\mu} + \dots + a_{n\mu}A_{n\mu}) = x_\mu \Delta = 0,$$

since from results already given the remaining coefficients of $x_1, x_2, \dots, x_{\mu-1}, x_{\mu+1}, \dots, x_n$ vanish identically.

Hence if Δ does not vanish $x_1 = x_2 = \dots = x_n = 0$ is the only solu-

tion; but if Δ vanishes the equations can be satisfied by a system of values other than zeros. For in this case the n equations are not independent since identically

$$A_{1\mu}f_1 + A_{2\mu}f_2 + \dots + A_{n\mu}f_n = 0,$$

and assuming that the minors do not all vanish the satisfaction of $n-1$ of the equations implies the satisfaction of the n^{th} .

Consider then the system of $n-1$ equations

$$\begin{aligned} a_{21}x_1 + a_{22}x_2 + \dots + a_{2n}x_n &= 0 \\ a_{31}x_1 + a_{32}x_2 + \dots + a_{3n}x_n &= 0 \\ &\dots \\ a_{n1}x_1 + a_{n2}x_2 + \dots + a_{nn}x_n &= 0, \end{aligned}$$

which becomes on writing $\frac{x_i}{x_n} = y_i$,

$$\begin{aligned} a_{21}y_1 + a_{22}y_2 + \dots + a_{2,n-1}y_{n-1} + a_{2n} &= 0 \\ a_{31}y_1 + a_{32}y_2 + \dots + a_{3,n-1}y_{n-1} + a_{3n} &= 0 \\ &\dots \\ a_{n1}y_1 + a_{n2}y_2 + \dots + a_{n,n-1}y_{n-1} + a_{nn} &= 0. \end{aligned}$$

We can solve these, assuming them independent, for the $n-1$ ratios y_1, y_2, \dots, y_{n-1} .

Now

$$\begin{aligned} a_{21}A_{11} + a_{22}A_{12} + \dots + a_{2n}A_{1n} &= 0 \\ a_{31}A_{11} + a_{32}A_{12} + \dots + a_{3n}A_{1n} &= 0 \\ &\dots \\ a_{n1}A_{11} + a_{n2}A_{12} + \dots + a_{nn}A_{1n} &= 0. \end{aligned}$$

and therefore, by comparison with the given equations, $x_i = \rho A_{1i}$, where ρ is an arbitrary factor which remains constant as i varies.

Hence $y_i = \frac{A_{1i}}{A_{1n}}$ where A_{1i} and A_{1n} are minors of the complete determinant $(a_{11}a_{22}\dots a_{nn})$.

$$\therefore y_i = (-)^{i+n} \frac{\begin{vmatrix} a_{21} & a_{22} & \dots & a_{2,i-1} & a_{2,i+1} & \dots & a_{2n} \\ a_{31} & a_{32} & \dots & a_{3,i-1} & a_{3,i+1} & \dots & a_{3n} \\ \dots & \dots & \dots & \dots & \dots & \dots & \dots \\ a_{n1} & a_{n2} & \dots & a_{n,i-1} & a_{n,i+1} & \dots & a_{nn} \end{vmatrix}}{\begin{vmatrix} a_{21} & a_{22} & \dots & a_{2,n-1} \\ a_{31} & a_{32} & \dots & a_{3,n-1} \\ \dots & \dots & \dots & \dots \\ a_{n1} & a_{n2} & \dots & a_{n,n-1} \end{vmatrix}},$$

or, in words, y_i is the quotient of the determinant obtained by erasing the i^{th} column by that obtained by erasing the n^{th} column, multiplied by $(-)^{i+n}$. For further information concerning the compatibility and independence of a system of linear equations, see Gordan, *Vorlesungen über Invariantentheorie*, Bd. 1, § 8.

Resultants.—When we are given k homogeneous equations in k variables or k non-homogeneous equations in $k-1$ variables, the equations being independent, it is always possible to derive from them a single equation $R=0$, where in R the variables do not appear. R is a function of the coefficients which is called the "resultant" or "eliminant" of the k equations, and the process by which it is obtained is termed "elimination." We cannot combine the equations so as to eliminate the variables unless on the supposition that the equations are simultaneous, i.e., each of them satisfied by a common system of values; hence the equation $R=0$ is derived on this supposition, and the vanishing of R expresses the condition that the equations can be satisfied by a common system of values assigned to the variables.

Consider two binary equations of orders m and n respectively expressed in non-homogeneous form, viz.

$$\begin{aligned} f(x) &= f = a_0x^m - a_1x^{m-1} + a_2x^{m-2} - \dots = 0, \\ \phi(x) &= \phi = b_0x^n - b_1x^{n-1} + b_2x^{n-2} - \dots = 0. \end{aligned}$$

If $\alpha_1, \alpha_2, \dots, \alpha_m$ be the roots of $f=0$, $\beta_1, \beta_2, \dots, \beta_n$ the roots of $\phi=0$, the condition that some root of $\phi=0$ may cause f to vanish is clearly

$$R_f \phi = f(\beta_1)f(\beta_2)\dots f(\beta_n) = 0;$$

so that $R_f \phi$ is the resultant of f and ϕ , and expressed as a function of the roots, it is of degree m in each root β , and of degree n in each root α , and also a symmetric function alike of the roots α and of the roots β ; hence, expressed in terms of the coefficients, it is homogeneous and of degree n in the coefficients of f , and homogeneous and of degree m in the coefficients of ϕ .

Ex. gr.

$$f = a_0x^2 - a_1x + a_2 = 0, \quad \phi = b_0x^2 - b_1x + b_2.$$

We have to multiply $a_0\beta_1^2 - a_1\beta_1 + a_2$ by $a_0\beta_2^2 - a_1\beta_2 + a_2$ and we obtain

$$a_0^2\beta_1^2\beta_2^2 - a_0a_1(\beta_1^2\beta_2 + \beta_1\beta_2^2) + a_0a_2(\beta_1^2 + \beta_2^2) + a_1^2\beta_1\beta_2 - a_1a_2(\beta_1 + \beta_2) + a_2^2,$$

where

$$\beta_1 + \beta_2 = \frac{b_1}{b_0}, \quad \beta_1\beta_2 = \frac{b_2}{b_0}, \quad \beta_1^2 + \beta_2^2 = \frac{b_1^2 - 2b_0b_2}{b_0^2},$$

and clearing of fractions

$$R_f \phi = (a_0b_2 - a_2b_0)^2 + (a_1b_0 - a_0b_1)(a_1b_2 - a_2b_1).$$

We may equally express the result as

$$\phi(a_1)\phi(a_2)\dots\phi(a_m)=0,$$

or as

$$\prod_{s,t}(\alpha_s - \beta_t) = 0.$$

This expression of R shows that, as will afterwards appear, the resultant is a simultaneous invariant of the two forms.

The resultant being a product of mn root differences, is of degree mn in the roots, and hence is of weight mn in the coefficients of the forms; i. e., the sum of the suffixes in each term of the resultant is equal to mn .

Resultant Expressible as a Determinant.—From the theory of linear equations it can be gathered that the condition that p linear equations in p variables (homogeneous and independent) may be simultaneously satisfied is expressible as a determinant, viz., if

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + \dots + a_{1p}x_p &= 0, \\ a_{21}x_1 + a_{22}x_2 + \dots + a_{2p}x_p &= 0, \end{aligned}$$

$$a_{p1}x_1 + a_{p2}x_2 + \dots + a_{pp}x_p = 0,$$

be the system the condition is, in determinant form,

$$(a_{11}a_{22}\dots a_{pp}) = 0;$$

in fact the determinant is the resultant of the equations.

Now, suppose f and ϕ to have a common factor $x - \gamma$,

$$f(x) = f_1(x)(x - \gamma); \quad \phi(x) = \phi_1(x)(x - \gamma),$$

f_1 and ϕ_1 being of degrees $m - 1$ and $n - 1$ respectively; we have the identity $\phi_1(x)f(x) = f_1(x)\phi(x)$ of degree $m + n - 1$.

Assuming then ϕ_1 to have the coefficients B_1, B_2, \dots, B_n and f_1 the coefficients A_1, A_2, \dots, A_m , we may equate coefficients of like powers of x in the identity, and obtain $m + n$ homogeneous linear equations satisfied by the $m + n$ quantities $B_1, B_2, \dots, B_n, A_1, A_2, \dots, A_m$. Forming the resultant of these equations we evidently obtain the resultant of f and ϕ .

Thus to obtain the resultant of

$$f = a_0x^m + a_1x^{m-1} + a_2x^{m-2} + a_3x^{m-3} + \dots, \quad \phi = b_0x^n + b_1x^{n-1} + b_2x^{n-2} + \dots,$$

we assume the identity

$$(B_0x + B_1)(a_0x^m + a_1x^{m-1} + a_2x^{m-2} + a_3x^{m-3} + \dots) = (A_0x^m + A_1x^{m-1} + A_2x^{m-2} + \dots)(b_0x^n + b_1x^{n-1} + b_2x^{n-2} + \dots),$$

and derive the linear equations

$$\begin{aligned} B_0a_0 &= -A_0b_0 = 0, \\ B_0a_1 + B_1a_0 - A_0b_1 - A_1b_0 &= 0, \\ B_0a_2 + B_1a_1 - A_0b_2 - A_1b_1 - A_2b_0 &= 0, \\ B_0a_3 + B_1a_2 &= -A_1b_2 - A_2b_1 = 0, \\ B_1a_3 &= -A_2b_2 = 0, \end{aligned}$$

and by elimination we obtain the resultant

$$\begin{vmatrix} a_0 & 0 & b_0 & 0 & 0 \\ a_1 & a_0 & b_1 & b_0 & 0 \\ a_2 & a_1 & b_2 & b_1 & b_0 \\ a_3 & a_2 & 0 & b_2 & b_1 \\ 0 & a_3 & 0 & 0 & b_2 \end{vmatrix} \begin{array}{l} \text{a numerical factor} \\ \text{being disregarded.} \end{array}$$

This is Euler's method. Sylvester's leads to the same expression, but in a simpler manner.

He forms n equations from f by separate multiplication by $x^{n-1}, x^{n-2}, \dots, x, 1$, in succession, and similarly treats ϕ with m multipliers $x^{m-1}, x^{m-2}, \dots, x, 1$. From these $m + n$ equations he eliminates the $m + n$ powers $x^{m+n-1}, x^{m+n-2}, \dots, x, 1$, treating them as independent unknowns. Taking the same example as before the process leads to the system of equations

$$\begin{aligned} a_0x^m + a_1x^{m-1} + a_2x^{m-2} + a_3x^{m-3} &= 0, \\ a_0x^{m-1} + a_1x^{m-2} + a_2x^{m-3} + a_3x^{m-4} &= 0, \\ b_0x^n + b_1x^{n-1} + b_2x^{n-2} &= 0, \\ b_0x^{n-1} + b_1x^{n-2} + b_2x^{n-3} &= 0, \end{aligned}$$

whence by elimination the resultant

$$\begin{vmatrix} a_0 & a_1 & a_2 & a_3 & 0 \\ 0 & a_0 & a_1 & a_2 & a_3 \\ b_0 & b_1 & b_2 & 0 & 0 \\ 0 & b_0 & b_1 & b_2 & 0 \\ 0 & 0 & b_0 & b_1 & b_2 \end{vmatrix}$$

which reads by columns as the former determinant reads by rows, and is therefore identical with the former. Bezout's method gives the resultant in the form of a determinant of order m or n , according as $m \geq n$. As modified by Cayley it takes a very simple form. He forms the equation

$$f(x)\phi(x') - f(x')\phi(x) = 0,$$

which can be satisfied when f and ϕ possess a common factor. He first divides by the factor $x - x'$, reducing it to the degree $m - 1$ in both x and x' where $m > n$; he then forms m equations by equating to zero the coefficients of the various powers of x ;

these equations involve the m powers $x^0, x, x^2, \dots, x^{m-1}$ of x , and regarding these as the unknowns of a system of linear equations the resultant is reached in the form of a determinant of order m . *Ex. gr.* Put

$$(a_0x^m + a_1x^{m-1} + a_2x^{m-2} + a_3x^{m-3} + \dots)(b_0x^n + b_1x^{n-1} + b_2x^{n-2} + \dots) - (a_0x'^m + a_1x'^{m-1} + a_2x'^{m-2} + a_3x'^{m-3} + \dots)(b_0x'^n + b_1x'^{n-1} + b_2x'^{n-2} + \dots) = 0;$$

after division by $x - x'$ the three equations are formed

$$\begin{aligned} a_0b_0x^m + a_0b_1x^{m-1} + a_0b_2x^{m-2} &= 0, \\ a_0b_1x^{m-1} + (a_0b_2 + a_1b_1 - a_2b_0)x^{m-2} + a_1b_2 - a_2b_0 &= 0, \\ a_0b_2x^{m-2} + (a_1b_2 - a_2b_0)x^{m-3} + a_2b_2 - a_3b_1 &= 0, \end{aligned}$$

and thence the resultant

$$\begin{vmatrix} a_0b_0 & a_0b_1 & a_0b_2 \\ a_0b_1 & a_0b_2 + a_1b_1 - a_2b_0 & a_1b_2 - a_2b_0 \\ a_0b_2 & a_1b_2 - a_2b_0 & a_2b_2 - a_3b_1 \end{vmatrix}$$

which is a symmetrical determinant.

Case of Three Variables.—In the next place we consider the resultants of three homogeneous polynomials in three variables. We can prove that if the three equations are satisfied by a system of values of the variable, the same system will also satisfy the Jacobian or functional determinant. For if u, v, w be the polynomials of orders m, n, p respectively, the Jacobian is $(u_1 v_2 w_3)$, and by Euler's theorem of homogeneous functions

$$\begin{aligned} xu_1 + yu_2 + zu_3 &= mu \\ xv_1 + yv_2 + zv_3 &= nu \\ xw_1 + yw_2 + zw_3 &= pw \end{aligned}$$

denoting now the reciprocal determinant by $(U_1 V_2 W_3)$ we obtain $Jx = muU_1 + nvV_2 + pwW_3$; $Jy = \dots$, $Jz = \dots$, and it appears that the vanishing of u, v, w implies the vanishing of J . Further, if $m = n = p$, we obtain by differentiation

$$J + x \frac{\partial J}{\partial x} = m \left(u \frac{\partial U_1}{\partial x} + v \frac{\partial V_1}{\partial x} + w \frac{\partial W_1}{\partial x} + u_1 U_1 + v_1 V_1 + w_1 W_1 \right),$$

or

$$x \frac{\partial J}{\partial x} = (m - 1)J + m \left(u \frac{\partial U_1}{\partial x} + v \frac{\partial V_1}{\partial x} + w \frac{\partial W_1}{\partial x} \right).$$

Hence the system of values also causes $\frac{\partial J}{\partial x}$ to vanish in this case;

and by symmetry $\frac{\partial J}{\partial y}$ and $\frac{\partial J}{\partial z}$ also vanish.

The proof being of general application we may state that a system of values which causes the vanishing of k polynomials in k variables causes also the vanishing of the Jacobian, and in particular, when the forms are of the same degree, the vanishing also of the differential coefficients of the Jacobian in regard to each of the variables.

There is no difficulty in expressing the resultant by the method of symmetric functions. Taking two of the equations

$$\begin{aligned} ax^m + (by + cz)x^{m-1} + \dots &= 0, \\ a'x^m + (b'y + c'z)x^{m-1} + \dots &= 0, \end{aligned}$$

we find that, eliminating x , the resultant is a homogeneous function of y and z of degree mn ; equating this to zero and solving for the ratio of y to z we obtain mn solutions; if values of y and z , given by any solution, be substituted in each of the two equations, they will possess a common factor which gives a value of x which, combined with the chosen values of y and z , yields a system of values which satisfies both equations. Hence in all there are mn such systems. If, therefore, we have a third equation, and we substitute each system of values in it successively and form the product of the mn expressions thus formed, we obtain a function which vanishes if any one system of values, common to the first two equations, also satisfies the third. Hence this product is the required resultant of the three equations.

Now by the theory of symmetric functions, any symmetric functions of the mn values which satisfy the two equations, can be expressed in terms of the coefficient of those equations. Hence, finally, the resultant is expressed in terms of the coefficients of the three equations, and since it is at once seen to be of degree mn in the coefficient of the third equation, by symmetry it must be of degrees np and pm in the coefficients of the first and second equations respectively. Its weight will be mnp (see Salmon's *Higher Algebra*, 4th ed. § 77). The general theory of the resultant of k homogeneous equations in k variables presents no further difficulties when viewed in this manner.

The expression in form of a determinant presents in general considerable difficulties. If three equations, each of the second degree, in three variables be given, we have merely to eliminate the six products $x^2, y^2, z^2, yz, zx, xy$ from the six equations $u = v = w = \frac{\partial J}{\partial x} = \frac{\partial J}{\partial y} = \frac{\partial J}{\partial z} = 0$; if we apply the same process to these equations, each of degree three, we obtain similarly a deter-

minant of order 21, but thereafter the process fails. Cayley, however, has shown that, whatever be the degrees of the three equations, it is possible to represent the resultant as the quotient of two determinants (Salmon, *l.c.* p. 89).

Discriminants.—The discriminant of a homogeneous polynomial in k variables is the resultant of the k polynomials formed by differentiations in regard to each of the variables.

It is the resultant of k polynomials each of degree $m-1$, and thus contains the coefficients of each form to the degree $(m-1)^{k-1}$; hence the total degrees in the coefficients of the k forms is, by addition, $k(m-1)^{k-1}$; it may further be shown that the weight of each term of the resultant is constant and equal to $m(m-1)^{k-1}$ (Salmon, *l.c.* p. 100).

A binary form which has a square factor has its discriminant equal to zero. This can be seen at once because the factor in question, being once repeated in both differentials, the resultant of the latter must vanish.

Similarly, if a form in k variables be expressible as a quadratic function of $k-1$, linear functions X_1, X_2, \dots, X_{k-1} , the coefficients being any polynomials, it is clear that the k differentials have, in common, the system of roots derived from $X_1 = X_2 = \dots = X_{k-1} = 0$, and have in consequence a vanishing resultant. This implies the vanishing of the discriminant of the original form.

Expression in Terms of Roots.—Since $x \frac{\partial f}{\partial x} + y \frac{\partial f}{\partial y} = mf$, if we take

any root x_1, y_1 , of $\frac{\partial f}{\partial x}$, and substitute in mf we must obtain $y_1 \left(\frac{\partial f}{\partial y} \right)_{x=x_1, y=y_1}$; hence the resultant of $\frac{\partial f}{\partial x}$ and f is, disregarding

numerical factors, $y_1 y_2 \dots y_{m-1} \times$ discriminant of $f = a_0 \times$ disct. of f .

Now

$$f = (x y_1 - x_1 y)(x y_2 - x_2 y) \dots (x y_m - x_m y),$$

$$\frac{\partial f}{\partial x} = \sum y_1 (x y_2 - x_2 y) \dots (x y_m - x_m y),$$

and substituting in the latter any root of f and forming the product, we find the resultant of f and $\frac{\partial f}{\partial x}$, viz. :—

$$y_1 y_2 \dots y_m (x_1 y_2 - x_2 y_1)^2 (x_1 y_3 - x_3 y_1)^2 \dots (x_r y_s - x_s y_r)^2 \dots$$

and, dividing by $y_1 y_2 \dots y_m$, the discriminant of f is seen to be equal to the product of the squares of all the differences of any two roots of the equation. The discriminant of the product of two forms is equal to the product of their discriminants multiplied by the square of their resultant. This follows at once from the fact that the discriminant is

$$\Pi(\alpha_r - \alpha_s)^2 \Pi(\beta_r - \beta_s)^2 \{ \Pi(\alpha_r - \beta_s) \}^2.$$

References for the Theory of Determinants.—T. MUIR'S "List of Writings on Determinants," *Quarterly Journal of Mathematics*, v. 18, pp. 110-149, October 1881, is the most important bibliographical article on the subject in any language; it contains 489 entries, arranged in chronological order, the first date being 1693 and the last 1880.—T. MUIR, *History of the Theory of Determinants*. London, 1890.—School treatises are those of THOMSON, MANSION, BARTL, MOLLAME, in English, French, German, and Italian respectively.—Advanced treatises are those of SPOTTISWOODE, 1851; BRIOCHI, 1854; BALTZER, 1857; SALMON, 1859; TRUDI, 1862; GABBIERI, 1874; GÜNTHER, 1875; DOSTOR, 1877; BARANIECKI (the most extensive of all), 1879; SCOTT, 1880; MUIR, 1881.

II. THE THEORY OF SYMMETRIC FUNCTIONS.

Consider n quantities $a_1, a_2, a_3, \dots, a_n$. Every rational integral function of these quantities, which does not alter its value however the n suffixes 1, 2, 3, ... n be permuted, is a rational integral symmetric function of the quantities. If we write $(1+a_1x)(1+a_2x)\dots(1+a_nx) = 1+a_1x+a_2x^2+\dots+a_nx^n$, a_1, a_2, \dots, a_n are called the elementary symmetric functions.

$$a_1 = a_1 + a_2 + \dots + a_n = \Sigma a_1$$

$$a_2 = a_1 a_2 + a_1 a_3 + a_2 a_3 + \dots = \Sigma a_1 a_2$$

$$\dots$$

$$a_n = a_1 a_2 a_3 \dots a_n.$$

The general monomial symmetric function is

$$\Sigma a_1^{p_1} a_2^{p_2} a_3^{p_3} \dots a_n^{p_n},$$

the summation being for all permutations of the indices which result in different terms. The function is written

$$(p_1 p_2 p_3 \dots p_n)$$

for brevity, and repetitions of numbers in the bracket are indicated by exponents, so that $(p_1 p_1 p_2)$ is written $(p_1^2 p_2)$. The

weight of the function is the sum of the numbers in the bracket, and the degree the highest of those numbers.

Ex. gr. The elementary functions are denoted by

$$(1), (1^2), (1^3), \dots (1^n),$$

are all of the first degree, and are of weights 1, 2, 3, ... n respectively.

Remark.—In this notation $(0) = \Sigma a_1^0 = \binom{n}{1}$; $(0^2) = \Sigma a_1^0 a_2^0 = \binom{n}{2}$; ... $(0^n) = \binom{n}{n}$, &c. The binomial coefficients appear, in fact, as symmetric functions, and this is frequently of importance.

The order of the numbers in the bracket $(p_1 p_2 \dots p_n)$ is immaterial; we may therefore always place them, as is most convenient, in descending order of magnitude; the numbers then constitute an ordered partition of the weight w , and the leading number denotes the degree.

The sum of the monomial functions of a given weight is called the *homogeneous-product-sum* or complete symmetric function of that weight; it is denoted by h_w ; it is connected with the elementary functions by the formula

$$\frac{1}{1 - a_1 x + a_2 x^2 - a_3 x^3 + \dots} = 1 + h_1 x + h_2 x^2 + h_3 x^3 + \dots,$$

which remains true when the symbols a and h are interchanged, as is at once evident by writing $-x$ for x . This proves, also, that in *any* formula connecting a_1, a_2, a_3, \dots with h_1, h_2, h_3, \dots the symbols a and h may be interchanged.

Ex. gr. from $h_2 = a_1^2 - a_2$ we derive $a_2 = h_1^2 - h_2$.

The function $\Sigma a_1^{p_1} a_2^{p_2} \dots a_n^{p_n}$ being as above denoted by a partition of the weight, viz. $(p_1 p_2 \dots p_n)$, it is necessary to bring under view other functions associated with the same series of numbers: such, for example, as

$$\Sigma a_1^{p_1} a_2^{p_2} \Sigma a_1^{p_2} a_2^{p_1} \dots \Sigma a_1^{p_{n-2}} a_2^{p_{n-2}} = (p_1 p_2)(p_2 p_1 \dots p_{n-2}).$$

The expression just written is in fact a partition of a partition, and to avoid confusion of language will be termed a *separation* of a partition. A partition is *separated* into *separates* so as to produce a separation of the partition by writing down a set of partitions, each separate partition in its own brackets, so that when all the parts of these partitions are reassembled in a single bracket the partition which is separated is reproduced. It is convenient to write the distinct partitions or separates in descending order as regards weight. If the successive weights of the separates w_1, w_2, w_3, \dots be enclosed in a bracket we obtain a partition of the weight w which appertains to the separated partition. This partition is termed the *specification* of the separation. The degree of the separation is the sum of the degrees of the component separates. A separation is the symbolic representation of a product of monomial symmetric functions. A partition; $(p_1 p_1 p_2 p_2 p_3)$ can be separated in the manner $(p_1 p_2)(p_1 p_2)(p_1 p_3) = (p_1 p_2)^2 (p_1 p_3)$, and we may take the general form of a partition to be $(p_1^{r_1} p_2^{r_2} p_3^{r_3} \dots)$ and that of a separation $(J_1)^{s_1} (J_2)^{s_2} (J_3)^{s_3} \dots$ when J_1, J_2, J_3, \dots denote the distinct separates involved.

Theorem.—The function symbolized by (n) , viz., the sum of the n^{th} powers of the quantities, is expressible in terms of functions which are symbolized by separations of *any* partition $(n_1^{r_1} n_2^{r_2} n_3^{r_3} \dots)$ of the number n . The expression is—

$$(-)^{v_1+v_2+v_3+\dots} \frac{(v_1+v_2+v_3+\dots-1)!}{v_1! v_2! v_3! \dots} (n)$$

$$= \sum (-)^{j_1+j_2+j_3+\dots} \frac{(j_1+j_2+j_3+\dots-1)!}{j_1! j_2! j_3! \dots} (J_1)^{s_1} (J_2)^{s_2} (J_3)^{s_3} \dots,$$

$(J_1)^{s_1} (J_2)^{s_2} (J_3)^{s_3} \dots$ being a separation of $(n_1^{r_1} n_2^{r_2} n_3^{r_3} \dots)$ and the summation being in regard to all such separations. For the

particular case $(n_1^{r_1} n_2^{r_2} n_3^{r_3} \dots) = (1^n)$

$$(-)^{n-1} (n) = \sum (-)^{j_1+j_2+j_3+\dots} \frac{(j_1+j_2+j_3+\dots-1)!}{j_1! j_2! j_3! \dots} (1)^{s_1} (1^2)^{s_2} (1^3)^{s_3} \dots$$

To establish this write—

$$1 + \mu X_1 + \mu^2 X_2 + \mu^3 X_3 + \dots = \Pi (1 + \mu a_1 x_1 + \mu^2 a_1^2 x_2 + \mu^3 a_1^3 x_3 + \dots),$$

the product on the right involving a factor for each of the quantities a_1, a_2, a_3, \dots , and μ being arbitrary.

Multiplying out the right-hand side and comparing coefficients

$$X_1 = (1)x_1,$$

$$X_2 = (2)x_2 + (1^2)x_1^2,$$

$$X_3 = (3)x_3 + (21)x_2 x_1 + (1^3)x_1^3,$$

$$X_4 = (4)x_4 + (31)x_3 x_1 + (2^2)x_2^2 + (21^2)x_2 x_1^2 + (1^4)x_1^4,$$

$$X_m = \Sigma (n_1^{r_1} n_2^{r_2} n_3^{r_3} \dots) a_1^{r_1} a_2^{r_2} a_3^{r_3} \dots,$$

the summation being for all partitions of m .

Auxiliary Theorem.—The coefficient of $x_1^{\lambda_1} x_2^{\lambda_2} x_3^{\lambda_3} \dots$ in the product $\frac{X^{\mu_1} X^{\mu_2} X^{\mu_3} \dots}{\mu_1! \mu_2! \mu_3! \dots}$ is $\sum \frac{(J_1)^{j_1} (J_2)^{j_2} (J_3)^{j_3} \dots}{j_1! j_2! j_3! \dots}$ where $(J_1)^{j_1} (J_2)^{j_2} (J_3)^{j_3} \dots$ is a separation of $(l_1^{\lambda_1} l_2^{\lambda_2} l_3^{\lambda_3} \dots)$ of specification $(m_1^{\mu_1} m_2^{\mu_2} m_3^{\mu_3} \dots)$, and the sum is for all such separations.

To establish this observe the result.

$$\frac{1}{p!} X^p = \sum \frac{(3)^{\pi_1} (21)^{\pi_2} (1^3)^{\pi_3}}{\pi_1! \pi_2! \pi_3!} x_3^{\pi_1} x_2^{\pi_2} x_1^{\pi_3 + 3\pi_3}$$
 and remark that

$(3)^{\pi_1} (21)^{\pi_2} (1^3)^{\pi_3}$ is a separation of $(3^{\pi_1} 2^{\pi_2} 1^{\pi_3 + 3\pi_3})$ of specification (3^{π_3}) . A similar remark may be made in respect of

$$\frac{1}{\mu_1!} X^{\mu_1}, \frac{1}{\mu_2!} X^{\mu_2}, \frac{1}{\mu_3!} X^{\mu_3}, \dots$$

and therefore of the product of these expressions. Hence the theorem.

Now

$$\log(1 + \mu X_1 + \mu^2 X_2 + \mu^3 X_3 + \dots) = \sum_a \log(1 + \mu a_1 x_1 + \mu^2 a_2^2 x_2 + \mu^3 a_3^3 x_3 + \dots)$$

whence expanding by the exponential and multinomial theorems a comparison of the coefficients of μ^n gives

$$(n) \sum (-)^{\nu_1 + \nu_2 + \nu_3 + \dots - 1} \frac{(\nu_1 + \nu_2 + \nu_3 + \dots - 1)!}{\nu_1! \nu_2! \nu_3! \dots} x_{n_1}^{\nu_1} x_{n_2}^{\nu_2} x_{n_3}^{\nu_3} \dots = \sum (-)^{\nu_1 + \nu_2 + \nu_3 + \dots - 1} \frac{(\nu_1 + \nu_2 + \nu_3 + \dots - 1)!}{\nu_1! \nu_2! \nu_3! \dots} X_{n_1}^{\nu_1} X_{n_2}^{\nu_2} X_{n_3}^{\nu_3} \dots$$

and, by the auxiliary theorem, any term $X_{m_1}^{\mu_1} X_{m_2}^{\mu_2} X_{m_3}^{\mu_3} \dots$ on the right-hand side is such that the coefficient of $x_{n_1}^{\nu_1} x_{n_2}^{\nu_2} x_{n_3}^{\nu_3} \dots$ in

$$\frac{1}{\mu_1! \mu_2! \mu_3! \dots} X_{m_1}^{\mu_1} X_{m_2}^{\mu_2} X_{m_3}^{\mu_3} \dots \text{ is } \sum \frac{(J_1)^{j_1} (J_2)^{j_2} (J_3)^{j_3} \dots}{j_1! j_2! j_3! \dots},$$

where since $(m_1^{\mu_1} m_2^{\mu_2} m_3^{\mu_3} \dots)$ is the specification of $(J_1)^{j_1} (J_2)^{j_2} (J_3)^{j_3} \dots$, $\mu_1 + \mu_2 + \mu_3 + \dots = j_1 + j_2 + j_3 + \dots$. Comparison of the coefficients of $x_{n_1}^{\nu_1} x_{n_2}^{\nu_2} x_{n_3}^{\nu_3} \dots$ therefore yields the result

$$(-)^{\nu_1 + \nu_2 + \nu_3 + \dots} \frac{(\nu_1 + \nu_2 + \nu_3 + \dots - 1)!}{\nu_1! \nu_2! \nu_3! \dots} (n) = \sum (-)^{j_1 + j_2 + j_3 + \dots} \frac{(j_1 + j_2 + j_3 + \dots - 1)!}{j_1! j_2! j_3! \dots} (J_1)^{j_1} (J_2)^{j_2} (J_3)^{j_3} \dots,$$

for the expression of Σa^n in terms of products of symmetric functions symbolized by separations of $(n_1^{\nu_1} n_2^{\nu_2} n_3^{\nu_3} \dots)$.

Let $(n)_a$, $(n)_x$, $(n)_x$ denote the sums of the n^{th} powers of quantities whose elementary symmetric functions are a_1, a_2, a_3, \dots ; x_1, x_2, x_3, \dots ; X_1, X_2, X_3, \dots respectively: then the result arrived at above from the logarithmic expansion may be written

$$(n)_a (n)_x = (n)_x,$$

exhibiting $(n)_x$ as an invariant of the transformation given by the expressions of X_1, X_2, X_3, \dots in terms of x_1, x_2, x_3, \dots .

The inverse question is the expression of any monomial symmetric function by means of the power functions $(r) = s_r$. We have just seen that s_r is expressible in terms of symmetric function products symbolized by separations of any partition $(p_1^{\rho_1} p_2^{\rho_2} p_3^{\rho_3} \dots)$ of r .

Let this expression be denoted by $s(p_1^{\rho_1} p_2^{\rho_2} p_3^{\rho_3} \dots)$.

Theorem.—It can be shown that

$$(-)^{\Sigma \pi - 1} (p_1^{\pi_1} p_2^{\pi_2} p_3^{\pi_3} \dots) = \sum (-)^{\Sigma j - 1} \frac{(\Sigma \pi - 1)! (\Sigma \pi_1 - 1)! \dots}{j_1! j_2! j_3! \dots \pi_1! \pi_2! \dots \pi_{21}! \pi_{22}! \dots} s_{(j_1)^{j_1} (j_2)^{j_2} (j_3)^{j_3} \dots},$$

where

$$(J_1)^{j_1} (J_2)^{j_2} (J_3)^{j_3} \dots = (p_1^{\pi_1} p_2^{\pi_2} p_3^{\pi_3} \dots) \dots$$

denotes a separation of $(p_1^{\pi_1} p_2^{\pi_2} p_3^{\pi_3} \dots)$ and the summation is in regard to all such separations. If $(J_1), (J_2), (J_3), \dots$ be of weights i_1, i_2, i_3, \dots it is clear that the product $s_{(j_1)^{j_1} (j_2)^{j_2} (j_3)^{j_3} \dots}$ will appear on the right-hand side, and that $(i_1^{j_1} i_2^{j_2} i_3^{j_3} \dots)$ is a specification of a separation of $(p_1^{\pi_1} p_2^{\pi_2} p_3^{\pi_3} \dots)$.

Ex. gr. To express (21^2) in terms of power functions.

The separations of (21^2) are (i.) (21^2) , (ii.) $(21)(1)$; (iii.) $(2)(1^2)$, (iv.) $(2)(1)^2$ and the corresponding specifications (4) , (31) , (2^2) , (21^2) .

Hence the products $s_4, s_3 s_1, s_2^2, s_2 s_1^2$ will appear. From the formula

$$(21^2) = s_{(21^2)} - s_{(21)} s_{(1)} - \frac{1}{2} s_{(2)} s_{(1)^2} + \frac{1}{2} s_{(2)} s_{(1)}^2 = s_4 - s_3 s_1 - \frac{1}{2} s_2^2 + \frac{1}{2} s_2 s_1^2.$$

a result easy to verify.

Theorem of Reciprocity.—If

$$X_{m_1}^{\mu_1} X_{m_2}^{\mu_2} X_{m_3}^{\mu_3} \dots = \dots + \theta (s_1^{\sigma_1} s_2^{\sigma_2} s_3^{\sigma_3} \dots) x_{l_1}^{\lambda_1} x_{l_2}^{\lambda_2} x_{l_3}^{\lambda_3} \dots + \dots,$$

where θ is a numerical coefficient, then also

$$X_{s_1}^{\sigma_1} X_{s_2}^{\sigma_2} X_{s_3}^{\sigma_3} \dots = \dots + \theta (m_1^{\mu_1} m_2^{\mu_2} m_3^{\mu_3} \dots) x_{l_1}^{\lambda_1} x_{l_2}^{\lambda_2} x_{l_3}^{\lambda_3} \dots + \dots$$

We have found above that the coefficient of $x_{l_1}^{\lambda_1} x_{l_2}^{\lambda_2} x_{l_3}^{\lambda_3} \dots$ in the product $X_{m_1}^{\mu_1} X_{m_2}^{\mu_2} X_{m_3}^{\mu_3} \dots$ is

$$\mu_1! \mu_2! \mu_3! \dots \sum \frac{(J_1)^{j_1} (J_2)^{j_2} (J_3)^{j_3} \dots}{j_1! j_2! j_3! \dots},$$

the sum being for all separations of $(l_1^{\lambda_1} l_2^{\lambda_2} l_3^{\lambda_3} \dots)$ which have the specification $(m_1^{\mu_1} m_2^{\mu_2} m_3^{\mu_3} \dots)$. We can multiply out this expression so as to obtain a series of monomials of the form $\theta (s_1^{\sigma_1} s_2^{\sigma_2} s_3^{\sigma_3} \dots)$. It can be shown that the number θ enumerates distributions of a certain nature defined by the partitions $(m_1^{\mu_1} m_2^{\mu_2} \dots)$, $(s_1^{\sigma_1} s_2^{\sigma_2} \dots)$, $(l_1^{\lambda_1} l_2^{\lambda_2} \dots)$ and it is seen intuitively that the number θ remains unaltered when the first two of these partitions are interchanged (see COMBINATORIAL ANALYSIS). Hence the theorem is established.

Putting $x_1 = 1$ and $x_2 = x_3 = x_4 = \dots = 0$, we find a particular law of reciprocity given by Cayley and Betti,

$$(1^{m_1})^{\mu_1} (1^{m_2})^{\mu_2} (1^{m_3})^{\mu_3} \dots = \dots + \theta (s_1^{\sigma_1} s_2^{\sigma_2} s_3^{\sigma_3} \dots) + \dots, (1^{s_1})^{\sigma_1} (1^{s_2})^{\sigma_2} (1^{s_3})^{\sigma_3} \dots = \dots + \theta (m_1^{\mu_1} m_2^{\mu_2} m_3^{\mu_3} \dots) + \dots;$$

and another by putting $x_1 = x_2 = x_3 = \dots = 1$, for then X_m becomes h_m , and we have

$$h_{m_1}^{\mu_1} h_{m_2}^{\mu_2} h_{m_3}^{\mu_3} \dots = \dots + \theta' (s_1^{\sigma_1} s_2^{\sigma_2} s_3^{\sigma_3} \dots) + \dots, h_{s_1}^{\sigma_1} h_{s_2}^{\sigma_2} h_{s_3}^{\sigma_3} \dots = \dots + \theta' (m_1^{\mu_1} m_2^{\mu_2} m_3^{\mu_3} \dots) + \dots.$$

Theorem of Expressibility.—“If a symmetric function be symbolized by $(\lambda \mu \dots)$ and $(\lambda_1 \lambda_2 \lambda_3 \dots)$, $(\mu_1 \mu_2 \mu_3 \dots)$, $(\nu_1 \nu_2 \nu_3 \dots)$ be any partitions of λ, μ, ν, \dots respectively, the function $(\lambda \mu \nu \dots)$ is expressible by means of functions symbolized by separations of

$$(\lambda_1 \lambda_2 \lambda_3 \dots \mu_1 \mu_2 \mu_3 \dots \nu_1 \nu_2 \nu_3 \dots).”$$

For, writing as before,

$$X_{m_1}^{\mu_1} X_{m_2}^{\mu_2} X_{m_3}^{\mu_3} \dots = \Sigma \Sigma \theta (s_1^{\sigma_1} s_2^{\sigma_2} s_3^{\sigma_3} \dots) x_{l_1}^{\lambda_1} x_{l_2}^{\lambda_2} x_{l_3}^{\lambda_3} \dots, = \Sigma P x_{l_1}^{\lambda_1} x_{l_2}^{\lambda_2} x_{l_3}^{\lambda_3} \dots,$$

P is a linear function of separations of $(l_1^{\lambda_1} l_2^{\lambda_2} l_3^{\lambda_3} \dots)$ of specification $(m_1^{\mu_1} m_2^{\mu_2} m_3^{\mu_3} \dots)$, and if $X_{s_1}^{\sigma_1} X_{s_2}^{\sigma_2} X_{s_3}^{\sigma_3} \dots = \Sigma P' x_{l_1}^{\lambda_1} x_{l_2}^{\lambda_2} x_{l_3}^{\lambda_3} \dots$, P' is a linear function of separations of $(l_1^{\lambda_1} l_2^{\lambda_2} l_3^{\lambda_3} \dots)$ of specification $(s_1^{\sigma_1} s_2^{\sigma_2} s_3^{\sigma_3} \dots)$.

Suppose the separations of $(l_1^{\lambda_1} l_2^{\lambda_2} l_3^{\lambda_3} \dots)$ to involve k different specifications and form the k identities

$$X_{m_1}^{\mu_1} X_{m_2}^{\mu_2} X_{m_3}^{\mu_3} \dots = \Sigma P^{(s)} x_{l_1}^{\lambda_1} x_{l_2}^{\lambda_2} x_{l_3}^{\lambda_3} \dots \quad (s = 1, 2, \dots, k),$$

where $(m_1^{\mu_1} m_2^{\mu_2} m_3^{\mu_3} \dots)$ is one of the k specifications.

The law of reciprocity shows that

$$P^{(s)} = \Sigma \theta_{st} (m_1^{\mu_1} m_2^{\mu_2} m_3^{\mu_3} \dots),$$

viz. — a linear function of symmetric functions symbolized by the k specifications; and that $\theta_{st} = \theta_{ts}$. A table may be formed expressing the k expressions $P^{(1)}, P^{(2)}, \dots, P^{(k)}$ as linear functions of the k expressions $(m_1^{\mu_1} m_2^{\mu_2} m_3^{\mu_3} \dots)$, $s = 1, 2, \dots, k$, and the numbers θ_{st} occurring therein possess row and column symmetry. By solving k linear equations we similarly express the latter functions as linear functions of the former, and this table will also be symmetrical.

Theorem.—“The symmetric function $(m_1^{\mu_1} m_2^{\mu_2} m_3^{\mu_3} \dots)$ whose partition is a specification of a separation of the function symbolized by $(l_1^{\lambda_1} l_2^{\lambda_2} l_3^{\lambda_3} \dots)$ is expressible as a linear function of symmetric functions symbolized by separations of $(l_1^{\lambda_1} l_2^{\lambda_2} l_3^{\lambda_3} \dots)$ and a symmetrical table may be thus formed.” It is now to be remarked that the partition $(l_1^{\lambda_1} l_2^{\lambda_2} l_3^{\lambda_3} \dots)$ can be derived from

$(m_{1s}^{\mu_{1s}} m_{2s}^{\mu_{2s}} m_{3s}^{\mu_{3s}} \dots)$ by substituting for the numbers $m_{1s}, m_{2s}, m_{3s}, \dots$ certain partitions of those numbers (*vide* the definition of the specification of a separation).

Hence the theorem of expressibility enunciated above. A new statement of the law of reciprocity can be arrived at as follows:—
Since

$$P(s) = \mu_{1s}! \mu_{2s}! \mu_{3s}! \dots \sum \frac{(J_1)^{j_1} (J_2)^{j_2} (J_3)^{j_3} \dots}{j_1! j_2! j_3! \dots};$$

where $(J_1)^{j_1} (J_2)^{j_2} (J_3)^{j_3} \dots$ is a separation of $(\lambda_1^{\lambda_1} \lambda_2^{\lambda_2} \lambda_3^{\lambda_3} \dots)$ of specification $(m_{1s}^{\mu_{1s}} m_{2s}^{\mu_{2s}} m_{3s}^{\mu_{3s}} \dots)$, placing s under the summation sign to denote the specification involved;

$$\mu_{1s}! \mu_{2s}! \mu_{3s}! \dots \sum \frac{(J_1)^{j_1} (J_2)^{j_2} (J_3)^{j_3} \dots}{j_1! j_2! j_3! \dots} = \sum_{t=1}^{s-k} \theta_{st} (m_{1t}^{\mu_{1t}} m_{2t}^{\mu_{2t}} m_{3t}^{\mu_{3t}} \dots),$$

$$\mu_{1t}! \mu_{2t}! \mu_{3t}! \dots \sum \frac{(J_1)^{j_1} (J_2)^{j_2} (J_3)^{j_3} \dots}{j_1! j_2! j_3! \dots} = \sum_{s=1}^{s-k} \theta_{st} (m_{1s}^{\mu_{1s}} m_{2s}^{\mu_{2s}} m_{3s}^{\mu_{3s}} \dots),$$

where $\theta_{st} = \theta_{st}$.

Theorem of Symmetry.—If we form the separation function $\sum \frac{(J_1)^{j_1} (J_2)^{j_2} (J_3)^{j_3} \dots}{j_1! j_2! j_3! \dots}$ appertaining to the function $(\lambda_1^{\lambda_1} \lambda_2^{\lambda_2} \lambda_3^{\lambda_3} \dots)$, each separation having a specification $(m_{1s}^{\mu_{1s}} m_{2s}^{\mu_{2s}} m_{3s}^{\mu_{3s}} \dots)$, multiply by $\mu_{1s}! \mu_{2s}! \mu_{3s}! \dots$ and take therein the coefficient of the function $(m_{1t}^{\mu_{1t}} m_{2t}^{\mu_{2t}} m_{3t}^{\mu_{3t}} \dots)$, we obtain the same result as if we formed the separation function in regard to the specification $(m_{1t}^{\mu_{1t}} m_{2t}^{\mu_{2t}} m_{3t}^{\mu_{3t}} \dots)$, multiplied by $\mu_{1t}! \mu_{2t}! \mu_{3t}! \dots$ and took therein the coefficient of the function $(m_{1s}^{\mu_{1s}} m_{2s}^{\mu_{2s}} m_{3s}^{\mu_{3s}} \dots)$.

Ex. gr., take $(\lambda_1^{\lambda_1} \lambda_2^{\lambda_2} \dots) = (21^4)$; $(m_{1s}^{\mu_{1s}} m_{2s}^{\mu_{2s}} \dots) = (321)$; $(m_{1t}^{\mu_{1t}} m_{2t}^{\mu_{2t}} \dots) = (31^5)$; we find

$$(21)(1^2)(1) + (1^3)(2)(1) = \dots + 13(31^5) + \dots,$$

$$(21)(1)^3 = \dots + 13(321) + \dots,$$

The Differential Operators.—Starting with the relation

$$(1 + a_1 x)(1 + a_2 x) \dots (1 + a_n x) = 1 + a_1 x + a_2 x^2 + \dots + a_n x^n$$

multiply each side by $1 + \mu x$, thus introducing a new quantity μ ; we obtain

$$(1 + a_1 x)(1 + a_2 x) \dots (1 + a_n x)(1 + \mu x) = 1 + (a_1 + \mu)x + (a_2 + \mu a_1)x^2 + \dots$$

so that $f(a_1, a_2, a_3, \dots, a_n) = f$, a rational integral function of the elementary functions, is converted into

$$f(a_1 + \mu, a_2 + \mu a_1, \dots, a_n + \mu a_{n-1}) = f + \mu d_1 f + \frac{\mu^2}{2!} d_2^2 f + \frac{\mu^3}{3!} d_3^3 f + \dots$$

where

$$d_1 = \frac{\partial}{\partial a_1} + a_1 \frac{\partial}{\partial a_2} + a_2 \frac{\partial}{\partial a_3} + \dots + a_{n-1} \frac{\partial}{\partial a_n}$$

and d_1^s denotes, not s successive operations of d_1 , but the operator of order s obtained by raising d_1 to the s^{th} power symbolically as in Taylor's theorem in the Diff. Cal.

Write also $\frac{1}{s!} d_1^s = D_s$, so that

$$f(a_1 + \mu, a_2 + \mu a_1, \dots, a_n + \mu a_{n-1}) = f + \mu D_1 f + \mu^2 D_2 f + \mu^3 D_3 f + \dots$$

The introduction of the quantity μ converts the symmetric function $(\lambda_1 \lambda_2 \lambda_3 \dots)$ into

$$(\lambda_1 \lambda_2 \lambda_3 \dots) + \mu^{\lambda_1} (\lambda_2 \lambda_3 \dots) + \mu^{\lambda_2} (\lambda_1 \lambda_3 \dots) + \mu^{\lambda_3} (\lambda_1 \lambda_2 \dots) + \dots$$

Hence, if $f(a_1, a_2, \dots, a_n) = (\lambda_1 \lambda_2 \lambda_3 \dots)$,

$$(\lambda_1 \lambda_2 \lambda_3 \dots) + \mu^{\lambda_1} (\lambda_2 \lambda_3 \dots) + \mu^{\lambda_2} (\lambda_1 \lambda_3 \dots) + \mu^{\lambda_3} (\lambda_1 \lambda_2 \dots) + \dots = (1 + \mu D_1 + \mu^2 D_2 + \mu^3 D_3 + \dots) (\lambda_1 \lambda_2 \lambda_3 \dots).$$

Comparing coefficients of like powers of μ we obtain

$$D_{\lambda_1} (\lambda_1 \lambda_2 \lambda_3 \dots) = (\lambda_2 \lambda_3 \dots),$$

while $D_s (\lambda_1 \lambda_2 \lambda_3 \dots) = 0$ unless the partition $(\lambda_1 \lambda_2 \lambda_3 \dots)$ contains a part s . Further, if $D_{\lambda_1} D_{\lambda_2}$ denote successive operations of D_{λ_1} and D_{λ_2} ,

$$D_{\lambda_1} D_{\lambda_2} (\lambda_1 \lambda_2 \lambda_3 \dots) = (\lambda_3 \dots),$$

and the operations are evidently commutative.

Also $D_{p_1}^{\pi_1} D_{p_2}^{\pi_2} \dots D_{p_s}^{\pi_s} (\pi_1^{\pi_1} \pi_2^{\pi_2} \dots \pi_s^{\pi_s}) = 1$, and the law of operation of the operators D upon a monomial symmetric function is clear.

We have obtained the equivalent operations

$$1 + \mu D_1 + \mu^2 D_2 + \mu^3 D_3 + \dots = \overline{\exp} \mu d_1$$

where $\overline{\exp}$ denotes (by the rule over \exp) that the multiplication of operators is symbolic as in Taylor's theorem. d_1^s denotes, in fact, an operator of order s , but we may transform the right-hand side

so that we are only concerned with the successive performance of linear operations. For this purpose write

$$d_s = \partial_{a_s} + a_1 \partial_{a_{s+1}} + a_2 \partial_{a_{s+2}} + \dots$$

It has been shown (*vide* "Memoir on Symmetric Functions of the Roots of Systems of Equations," *Phil. Trans. R. S.*, London, 1890, p. 490) that

$$\overline{\exp}(m_1 d_1 + m_2 d_2 + m_3 d_3 + \dots) = \exp(M_1 d_1 + M_2 d_2 + M_3 d_3 + \dots),$$

where now the multiplications on the dexter denote successive operations, provided that

$$\exp(M_1 \xi + M_2 \xi^2 + M_3 \xi^3 + \dots) = 1 + m_1 \xi + m_2 \xi^2 + m_3 \xi^3 + \dots,$$

ξ being an undetermined algebraic quantity.

Hence we derive the particular cases

$$\overline{\exp} d_1 = \exp(d_1 - \frac{1}{2} d_2 + \frac{1}{3} d_3 - \dots);$$

$$\overline{\exp} \mu d_1 = \exp(\mu d_1 - \frac{1}{2} \mu^2 d_2 + \frac{1}{3} \mu^3 d_3 - \dots),$$

and we can express D_s in terms of d_1, d_2, d_3, \dots , products denoting successive operations, by the same law which expresses the elementary function a_s in terms of the sums of powers s_1, s_2, s_3, \dots . Further, we can express d_s in terms of D_1, D_2, D_3, \dots by the same law which expresses the power function s , in terms of the elementary functions a_1, a_2, a_3, \dots .

Operation of D_s upon a Product of Symmetric Functions.—Suppose f to be a product of symmetric functions $f_1 f_2 \dots f_m$. If in the identity $f = f_1 f_2 \dots f_m$ we introduce a new root μ we change a_s into $a_s + \mu a_{s-1}$, and we obtain

$$(1 + \mu D_1 + \mu^2 D_2 + \dots + \mu^s D_s + \dots) f = (1 + \mu D_1 + \mu^2 D_2 + \dots + \mu^s D_s + \dots) f_1 \times (1 + \mu D_1 + \mu^2 D_2 + \dots + \mu^s D_s + \dots) f_2 \times \dots \times (1 + \mu D_1 + \mu^2 D_2 + \dots + \mu^s D_s + \dots) f_m,$$

and now expanding and equating coefficients of like powers of μ

$$D_1 f = \Sigma (D_1 f_1) f_2 f_3 \dots f_m,$$

$$D_2 f = \Sigma (D_2 f_1) f_2 f_3 \dots f_m + \Sigma (D_1 f_1) (D_1 f_2) f_3 \dots f_m,$$

$$D_3 f = \Sigma (D_3 f_1) f_2 f_3 \dots f_m + \Sigma (D_2 f_1) (D_1 f_2) f_3 \dots f_m + \Sigma (D_3 f_1) f_2 f_3 \dots f_m,$$

the summation in a term covering every distribution of the operators of the type presenting itself in the term.

Writing these results

$$D_1 f = D_{(1)} f,$$

$$D_2 f = D_{(2)} f + D_{(1^2)} f,$$

$$D_3 f = D_{(3)} f + D_{(21)} f + D_{(1^3)} f,$$

we may write in general

$$D_s f = \Sigma D_{(p_1 p_2 p_3 \dots)} f,$$

the summation being for every partition $(p_1 p_2 p_3 \dots)$ of s , and $D_{(p_1 p_2 p_3 \dots)} f$ being $= \Sigma (D_{p_1} f_1) (D_{p_2} f_2) (D_{p_3} f_3) \dots f_m$.

Ex. gr. To operate with D_2 upon $(21^4)(1^5)$, we have

$$D_{(2)} f = (1^5)(21^4)(1^5) + (21^5)(1^4)(1^5),$$

$$D_{(1^2)} f = (21^2)(21^3)(1^5) + (21^3)(21^2)(1^4) + (21^3)(21^4)(1^4),$$

and hence

$$D_2 f = (21^4)(1^5)(1^5) + (21^5)(1^5)(1^4) + (21^5)(21^2)(1^5) + (21^3)^2(1^4) + (21^4)(21^2)(1^4).$$

Application to Symmetric Function Multiplication.—An example will explain this. Suppose we wish to find the coefficient of $(52^4 1^5)$ in the product $(21^2)(21^4)(1^5)$.

Write

$$(21^2)(21^4)(1^5) = \dots + A(52^4)(1^5) + \dots;$$

then

$$D_2 D_4 D_2^2 (21^2)(21^4)(1^5) = A;$$

every other term disappearing by the fundamental property of D_s . Since

$$D_5 (21^5)(21^4)(1^5) = (1^5)(1^4)(1^4),$$

we have:—

$$D_2^2 D_4^2 (1^4)(1^4)(1^5) = A$$

$$D_2^3 D_4^3 \{ (1^3)(1^3)(1^5) + 2(1^4)(1^3)(1^2) \} = A$$

$$D_2^4 D_4^4 \{ 5(1^5)(1^2)(1^3) + 2(1^4)(1^2)(1) + 2(1^3)(1^3)(1) \} = A$$

$$D_2^5 D_4^5 \{ 12(1^2)(1^2)(1) + 7(1^5)(1)(1) + 2(1^4)(1) + 6(1^3)(1^2) \} = A$$

$$D_2^6 12(1^3) = A,$$

where ultimately disappearing terms have been struck out. Finally $A = 6.12 = 72$.

The operator $d_1 = a_1 \partial_{a_1} + a_2 \partial_{a_2} + a_3 \partial_{a_3} + \dots$ which is satisfied by every symmetric fraction whose partition contains no unit (called by Cayley *non-unitary symmetric functions*), is of particular importance in algebraic theories. This arises from the circumstance that the general operator

$$\lambda_1 a_1 \partial_{a_1} + \lambda_2 a_2 \partial_{a_2} + \lambda_3 a_3 \partial_{a_3} + \dots$$

is transformed into the operator a_1 by the substitution

$$(a_0, a_1, a_2, \dots, a_n, \dots) = (a_0, \lambda_0 a_1, \lambda_0 \lambda_1 a_2, \dots, \lambda_0 \lambda_1 \dots \lambda_{n-1} a_n, \dots),$$

so that the theory of the general operator is coincident with that of the particular operator a_1 . For example, the theory of invariants may be regarded as depending upon the consideration of the symmetric functions of the differences of the roots of the equation

$$a_0 x^n - \binom{n}{1} a_1 x^{n-1} + \binom{n}{2} a_2 x^{n-2} - \dots = 0;$$

and such functions satisfy the differential equation

$$a_0 \partial a_1 + 2a_1 \partial a_2 + 3a_2 \partial a_3 + \dots + na_{n-1} \partial a_n = 0.$$

For such functions remain unaltered when each root receives the same infinitesimal increment h ; but writing $x-h$ for x causes $a_0, a_1, a_2, a_3, \dots$ to become respectively $a_0, a_1 + ha_0, a_2 + 2ha_1, a_3 + 3ha_2, \dots$ and $f(a_0, a_1, a_2, a_3, \dots)$ becomes

$$f + h(a_0 \partial a_1 + 2a_1 \partial a_2 + 3a_2 \partial a_3 + \dots) f,$$

and hence the functions satisfy the differential equation. The important result is that the theory of invariants is from a certain point of view coincident with the theory of non-unitary symmetric functions. On the one hand we may state that non-unitary symmetric functions of the roots of $a_0 x^n - a_1 x^{n-1} + a_2 x^{n-2} - \dots = 0$, are symmetric functions of differences of the roots of

$$a_0 x^n - 1! \binom{n}{1} a_1 x^{n-1} + 2! \binom{n}{2} a_2 x^{n-2} - \dots = 0;$$

and on the other hand that symmetric functions of the differences of the roots of

$$a_0 x^n - \binom{n}{1} a_1 x^{n-1} + \binom{n}{2} a_2 x^{n-2} - \dots = 0,$$

are non-unitary symmetric functions of the roots of

$$a_0 x^n - \frac{a_1}{1!} x^{n-1} + \frac{a_2}{2!} x^{n-2} - \dots = 0.$$

An important notion in the theory of linear operators in general is that of MacMahon's *multilinear operator* ("Theory of a Multilinear partial Differential Operator with Applications to the Theories of Invariants and Reciprocants," *Proc. Lond. Math. Soc.*, t. xviii. (1886), pp. 61-88). It is defined as having four elements, and is written

$$\begin{aligned} & (\mu, \nu; m, n) \\ &= \frac{1}{m} \left[\mu a_0^m \partial_{a_n} + (\mu + \nu) \frac{m!}{(m-1)! 1!} a_0^{m-1} a_1 \partial_{a_{n+1}} \right. \\ &+ (\mu + 2\nu) \left\{ \frac{m!}{(m-1)! 1! 1!} a_0^{m-1} a_2 + \frac{m!}{(m-2)! 2! 1!} a_0^{m-2} a_1^2 \right\} \partial_{a_{n+2}} \\ &+ (\mu + 3\nu) \left\{ \frac{m!}{(m-1)! 1! 1!} a_0^{m-1} a_3 + \frac{m!}{(m-2)! 1! 1! 1!} a_0^{m-2} a_1 a_2 \right. \\ &\quad \left. + \frac{m!}{(m-3)! 3! 1!} a_0^{m-3} a_3^3 \right\} \partial_{a_{n+3}} \\ &\quad \left. + \dots \right], \end{aligned}$$

the coefficient of $a_0^{k_0} a_1^{k_1} a_2^{k_2} \dots$ being $\frac{m!}{k_0! k_1! k_2! \dots}$. The operators $a_0 \partial_{a_1} + a_1 \partial_{a_2} + \dots, a_0 \partial_{a_1} + 2a_1 \partial_{a_2} + \dots$ are seen to be $(1, 0; 1, 1)$ and $(1, 1; 1, 1)$ respectively. Also the operator of the Theory of Pure Reciprocants (see *Sylvester Lectures on the New Theory of Reciprocants*, Oxford, 1888) is

$$(4, 1; 2, 1) = \frac{1}{2} \left\{ 4a_0^2 \partial_{a_1} + 10a_0 a_1 \partial_{a_2} + 6(2a_0 a_2 + a_1^2) \partial_{a_3} + \dots \right\}$$

It will be noticed that

$$(\mu, \nu; m, n) = \mu(1, 0; m, n) + \nu(0, 1; m, n).$$

The importance of the operator consists in the fact that taking any two operators of the system

$$(\mu, \nu; m, n); (\mu^1, \nu^1; m^1, n^1),$$

the operator equivalent to

$$(\mu, \nu; m, n)(\mu^1, \nu^1; m^1, n^1) - (\mu^1, \nu^1; m^1, n^1)(\mu, \nu; m, n),$$

known as the "alternant" of the two operators, is also an operator of the same system. We have the theorem

$$(\mu, \nu; m, n)(\mu^1, \nu^1; m^1, n^1) - (\mu^1, \nu^1; m^1, n^1)(\mu, \nu; m, n) = (\mu_1, \nu_1; m_1, n_1);$$

where

$$\mu_1 = (m^1 + m - 1) \left\{ \frac{\mu^1 \nu^1}{m^1} (\mu + \nu^1) - \frac{\mu}{m} (\mu^1 + \nu^1) \right\},$$

$$\nu_1 = (n^1 - n) \nu^1 \nu + \frac{m-1}{m^1} \mu^1 \nu - \frac{m^1-1}{m} \mu \nu^1,$$

$$m_1 = m^1 + m - 1,$$

$$n_1 = n^1 + n,$$

and we conclude that *quod* "alternation" the operators of the system form a "group." It is thus possible to study simultaneously all the theories which depend upon operations of the group.

Symbolic Representation of Symmetric Functions.—Denote the elementary symmetric function a_s by $\frac{a_1^s}{s!}, \frac{a_2^s}{s!}, \frac{a_3^s}{s!}, \dots$ at pleasure; then, taking n equal to ∞ , we may write

$$1 + a_1 x + a_2 x^2 + \dots = (1 + \rho_1 x)(1 + \rho_2 x) \dots = e^{\rho_1 x} e^{\rho_2 x} = e^{\rho_1 x + \rho_2 x} = \dots$$

where

$$a_s = \sum \rho_1 \rho_2 \dots \rho_s = \frac{a_1^s}{s!} = \frac{a_2^s}{s!} = \frac{a_3^s}{s!} = \dots$$

Further, let

$$1 + b_1 x + b_2 x^2 + \dots + b_m x^m = (1 + \sigma_1 x)(1 + \sigma_2 x) \dots (1 + \sigma_m x);$$

so that

$$1 + a_1 \sigma_1 + a_2 \sigma_1^2 + \dots = (1 + \rho_1 \sigma_1)(1 + \rho_2 \sigma_1) \dots = e^{\rho_1 \sigma_1},$$

$$1 + a_1 \sigma_2 + a_2 \sigma_2^2 + \dots = (1 + \rho_1 \sigma_2)(1 + \rho_2 \sigma_2) \dots = e^{\rho_2 \sigma_2},$$

$$1 + a_1 \sigma_m + a_2 \sigma_m^2 + \dots = (1 + \rho_1 \sigma_m)(1 + \rho_2 \sigma_m) \dots = e^{\rho_m \sigma_m};$$

and, by multiplication,

$$\prod (1 + a_1 \sigma + a_2 \sigma^2 + \dots) = \prod (1 + b_1 \rho + b_2 \rho^2 + \dots + b_m \rho^m),$$

$$= e^{\rho_1 a_1 + \rho_2 a_2 + \dots + \rho_m a_m}.$$

Denote by brackets $()$ and $[\]$ symmetric functions of the quantities ρ and σ respectively. Then

$$\begin{aligned} & 1 + a_1 [1] + a_2^2 [1^2] + a_3^3 [1^3] + a_1 a_2 [21] + a_3 [3] + \dots \\ &+ a_1 \rho_1 a_2 \rho_2 a_3 \dots a_m \rho_m [1^m] + \dots \\ &= 1 + b_1 (1) + b_2^2 (1^2) + b_3^3 (1^3) + b_1 b_2 (21) + b_3 (3) + \dots \\ &+ b_1^2 b_3 b_3^2 \dots b_m^m (m^m m-1^{m-1} \dots 2^2 1^1) + \dots \\ &= e^{\rho_1 a_1 + \rho_2 a_2 + \dots + \rho_m a_m}. \end{aligned}$$

Expanding the right-hand side by the exponential theorem, and then expressing the symmetric functions of $\sigma_1, \sigma_2, \dots, \sigma_m$, which arise, in terms of b_1, b_2, \dots, b_m , we obtain by comparison with the middle series the symbolical representation of all symmetric functions in brackets $()$ appertaining to the quantities $\rho_1, \rho_2, \rho_3, \dots$. To obtain particular theorems the quantities $\sigma_1, \sigma_2, \sigma_3, \dots, \sigma_m$ are auxiliaries which are at our entire disposal. Thus to obtain *Stroh's theory of seminvariants* put

$$b_1 = \sigma_1 + \sigma_2 + \dots + \sigma_m = [1] = 0;$$

we then obtain the expression of non-unitary symmetric functions of the quantities ρ as functions of differences of the symbols a_1, a_2, a_3, \dots

Ex. gr. $b_2^2 (2^2)$ with $m=2$ must be a term in

$$e^{\rho_1 a_1 + \rho_2 a_2} = e^{\rho_1 (a_1 - a_2)} = \dots + \frac{1}{4!} \sigma_1^4 (a_1 - a_2)^4 + \dots,$$

and since $b_2^2 = \sigma_1^4$ we must have

$$\begin{aligned} (2^2) &= \frac{1}{24} (a_1 - a_2)^4 = \frac{1}{24} (a_1^4 + a_2^4) - \frac{1}{6} (a_1^3 a_2 + a_1 a_2^3) + \frac{1}{4} a_1^2 a_2^2 \\ &= 2a_4 - 2a_1 a_3 + a_2^2 \end{aligned}$$

as is well known.

Again, if $\sigma_1, \sigma_2, \sigma_3, \dots, \sigma_m$ be the m, m^2 roots of $-1, b_1 = b_2 = \dots = b_{m-1} = 0$ and $b_m = 1$, leading to

$$1 + (m) + (m^2) + (m^3) + \dots = e^{\rho_1 a_1 + \rho_2 a_2 + \dots + \rho_m a_m}$$

and

$$\therefore (m^k) = \frac{1}{m^k} (\rho_1 a_1 + \rho_2 a_2 + \dots + \rho_m a_m)^m,$$

and we see further that $(\rho_1 a_1 + \rho_2 a_2 + \dots + \rho_m a_m)^k$ vanishes identically unless $k \equiv 0 \pmod m$. If m be infinite and

$$1 + b_1 x + b_2 x^2 + \dots = (1 + \sigma_1 x)(1 + \sigma_2 x) \dots = e^{\beta_1 x} = e^{\beta x} = \dots,$$

we have the symbolic identity

$$e^{\rho_1 a_1 + \rho_2 a_2 + \rho_3 a_3 + \dots} = e^{\rho_1 \beta_1 + \rho_2 \beta_2 + \rho_3 \beta_3 + \dots},$$

and

$$(\rho_1 a_1 + \rho_2 a_2 + \rho_3 a_3 + \dots)^p = (\rho_1 \beta_1 + \rho_2 \beta_2 + \rho_3 \beta_3 + \dots)^p.$$

Instead of the above symbols we may use equivalent differential operators. Thus let

$$\delta_a = a_1 \partial_{a_0} + 2a_2 \partial_{a_1} + 3a_3 \partial_{a_2} + \dots$$

and let a, b, c, \dots be equivalent quantities. Any function of differences of $\delta_a, \delta_b, \delta_c, \dots$ being formed the expansion being carried out, an operand a_0 or b_0 or c_0, \dots being taken and b, c, \dots being subsequently put equal to a , a non-unitary symmetric function will be produced.

$$\begin{aligned} \text{Ex. gr. } & (\delta_a - \delta_b)^2 (\delta_a - \delta_c) = (\delta_a^2 - 2\delta_a \delta_b + \delta_b^2) (\delta_a - \delta_c) \\ &= \delta_a^2 - 2\delta_a^2 \delta_b + \delta_a \delta_b^2 - \delta_a^2 \delta_c + 2\delta_a \delta_b \delta_c - \delta_b^2 \delta_c \\ &= 6a_3 - 4a_2 b_1 + 2a_1 b_2 - 2a_2 c_1 + 2a_1 b_1 c_1 - 2b_2 c_1 \\ &= 2(a_1^3 - 3a_1 a_2 + 3a_3) = 2(3). \end{aligned}$$

The whole theory of these forms is consequently contained implicitly in the operation δ .

Symmetric Functions of Several Systems of Quantities.—It will suffice to consider two systems of quantities as the corresponding theory for three or more systems is obtainable by an obvious enlargement of the nomenclature and notation.

Taking the systems of quantities to be

$$\begin{matrix} \alpha_1, \alpha_2, \alpha_3, \dots \\ \beta_1, \beta_2, \beta_3, \dots \end{matrix}$$

we start with the fundamental relation

$$(1 + \alpha_1 x + \beta_1 y)(1 + \alpha_2 x + \beta_2 y)(1 + \alpha_3 x + \beta_3 y) \dots = 1 + \alpha_1 x + \alpha_{01} y + \alpha_{20} x^2 + \alpha_{11} x y + \alpha_{02} y^2 + \dots + \alpha_{pq} x^p y^q + \dots$$

As shown by Schläfli* this equation may be directly formed and exhibited as the resultant of two given equations, and an arbitrary linear non-homogeneous equation in two variables. The right-hand side may be also written

$$1 + \Sigma \alpha_i x + \Sigma \beta_j y + \Sigma \alpha_i \alpha_j x^2 + \Sigma \alpha_i \beta_j x y + \Sigma \beta_i \beta_j y^2 + \dots$$

The most general symmetric function to be considered is

$$\Sigma \alpha_1^{\pi_1} \beta_1^{\pi_2} \alpha_2^{\pi_3} \beta_2^{\pi_4} \alpha_3^{\pi_5} \beta_3^{\pi_6} \dots$$

conveniently written in the symbolic form

$$(\overline{p_1 q_1 p_2 q_2 p_3 q_3 \dots})$$

Observe that the summation is in regard to the expressions obtained by permuting the n suffixes 1, 2, 3, ... n . The weight of the function is bipartite and consists of the two numbers Σp and Σq ; the symbolic expression of the symmetric function is a partition into biparts (multiparts) of the bipartite (multipartite) number $\Sigma p, \Sigma q$. Each part of the partition is a bipartite number, and in representing the partition it is convenient to indicate repetitions of parts by power symbols. In this notation the fundamental relation is written

$$(1 + \alpha_1 x + \beta_1 y)(1 + \alpha_2 x + \beta_2 y)(1 + \alpha_3 x + \beta_3 y) \dots = 1 + (\overline{10})x + (\overline{01})y + (\overline{10^2})x^2 + (\overline{10 \ 01})xy + (\overline{01^2})y^2 + (\overline{10^3})x^3 + (\overline{10^2 \ 01})x^2 y + (\overline{10 \ 01^2})x y^2 + (\overline{01^3})y^3 + \dots$$

where in general $\alpha_{pq} = (\overline{10^p \ 01^q})$.

All symmetric functions are expressible in terms of the quantities α_{pq} in a rational integral form; from this property they are termed elementary functions; further they are said to be single-unitary since each part of the partition denoting α_{pq} involves but a single unit.

The number of partitions of a biweight \overline{pq} into exactly μ biparts is given (after Euler) by the coefficient of $\alpha^{\mu} x^p y^q$ in the expansion of the generating function

$$\frac{1}{1 - \alpha x - \beta y - \alpha^2 x^2 - \beta^2 y^2 - \alpha \beta xy - \alpha^3 x^3 - \beta^3 y^3 - \alpha^2 \beta xy^2 - \alpha \beta^2 x^2 y - \alpha^4 x^4 - \beta^4 y^4 - \dots}$$

The partitions with one bipart correspond to the sums of powers in the single system or unipartite theory; they are readily expressed in terms of the elementary functions. For write $(\overline{pq}) = s_{pq}$ and take logarithms of both sides of the fundamental relation; we obtain

$$s_{10} x + s_{01} y = \Sigma (\alpha_1 x + \beta_1 y) \\ s_{20} x^2 + 2s_{11} xy + s_{02} y^2 = \Sigma (\alpha_1 x + \beta_1 y)^2, \text{ \&c.,}$$

and

$$s_{10} x + s_{01} y - \frac{1}{2}(s_{20} x^2 + 2s_{11} xy + s_{02} y^2) + \dots = \log (1 + \alpha_1 x + \beta_1 y + \dots + \alpha_{pq} x^p y^q + \dots)$$

From this formula we obtain by elementary algebra

$$(-)^{p+q-1} \frac{(p+q-1)!}{p!q!} s_{pq} = \sum_{\pi} (-)^{\Sigma \pi - 1} \frac{(\Sigma \pi - 1)!}{\pi_1! \pi_2! \dots} \alpha_{p_1 q_1}^{\pi_1} \alpha_{p_2 q_2}^{\pi_2} \dots$$

corresponding to Waring's formula for the single system. The analogous formula appertaining to n systems of quantities which expresses $s_{pq\dots}$ in terms of elementary functions can be at once written down.

Ex. gr. We can verify the relations

$$s_{20} = \alpha_{20}^2 - 3\alpha_{20} \alpha_{10} + 3\alpha_{10}^2$$

$$s_{11} = \alpha_{10}^2 \alpha_{01} - \alpha_{20} \alpha_{01} - \alpha_{11} \alpha_{10} + \alpha_{11}^2$$

The formula actually gives the expression of (\overline{pq}) by means of separations of

$$(\overline{10^p \ 01^q}),$$

which is one of the partitions of (\overline{pq}) . This is the true standpoint from which the theorem should be regarded. It is but a particular case of a general theory of expressibility.

To invert the formula we may write

$$1 + \alpha_1 x + \alpha_{01} y + \dots + \alpha_{pq} x^p y^q + \dots = \exp \left\{ (s_{10} x + s_{01} y) - \frac{1}{2}(s_{20} x^2 + 2s_{11} xy + s_{02} y^2) + \dots \right\}$$

* Vienna Transactions, t. iv. 1852.

and thence derive the formula—

$$(-)^{p+q-1} \alpha_{pq} = \sum \left\{ \frac{(p_1 + q_1 - 1)!}{p_1! q_1!} \right\}^{\pi_1} \left\{ \frac{(p_2 + q_2 - 1)!}{p_2! q_2!} \right\}^{\pi_2} \dots \frac{(-)^{\Sigma \pi - 1}}{\pi_1! \pi_2! \dots} \alpha_{p_1 q_1}^{\pi_1} \alpha_{p_2 q_2}^{\pi_2} \dots$$

which expresses the elementary functions in terms of the single bipart functions. The similar theorem for n systems of quantities can be at once written down.

It will be shown later that every rational integral symmetric function is similarly expressible.

The Function h_{pq} .—As the definition of h_{pq} we take

$$\frac{1 + h_{10} x + h_{01} y + \dots + h_{pq} x^p y^q + \dots}{(1 - \alpha_1 x - \beta_1 y)(1 - \alpha_2 x - \beta_2 y) \dots}$$

and now expanding the right-hand side

$$h_{pq} = \sum \left(\frac{p_1 + q_1}{p_1} \right) \left(\frac{p_2 + q_2}{p_2} \right) \dots (\overline{p_1 q_1 p_2 q_2 \dots}),$$

the summation being for all partitions of the biweight. Further writing

$$\frac{1 + h_{10} x + h_{01} y + \dots + h_{pq} x^p y^q + \dots}{1 - \alpha_1 x - \alpha_{01} y + \dots + (-)^{p+q} \alpha_{pq} x^p y^q + \dots}$$

we find that the effect of changing the signs of both x and y is merely to interchange the symbols a and h ; hence in any relation connecting the quantities h_{pq} with the quantities α_{pq} we are at liberty to interchange the symbols a and h . By the exponential and multinomial theorems we obtain the results—

$$(-)^{p+q-1} h_{pq} = \sum_{\pi} (-)^{\Sigma \pi - 1} \frac{(\Sigma \pi)!}{\pi_1! \pi_2! \dots} \alpha_{p_1 q_1}^{\pi_1} \alpha_{p_2 q_2}^{\pi_2} \dots$$

and in this a and h are interchangeable.

$$\frac{(p+q-1)!}{p!q!} s_{pq} = \sum_{\pi} (-)^{\Sigma \pi - 1} \frac{(\Sigma \pi - 1)!}{\pi_1! \pi_2! \dots} h_{p_1 q_1}^{\pi_1} h_{p_2 q_2}^{\pi_2} \dots$$

$$h_{pq} = \sum \left\{ \frac{(p_1 + q_1 - 1)!}{p_1! q_1!} \right\}^{\pi_1} \left\{ \frac{(p_2 + q_2 - 1)!}{p_2! q_2!} \right\}^{\pi_2} \dots \frac{1}{\pi_1! \pi_2! \dots} \alpha_{p_1 q_1}^{\pi_1} \alpha_{p_2 q_2}^{\pi_2} \dots$$

Differential Operations.—If, in the identity

$$(1 + \alpha_1 x + \beta_1 y)(1 + \alpha_2 x + \beta_2 y) \dots (1 + \alpha_n x + \beta_n y) = 1 + \alpha_{10} x + \alpha_{01} y + \alpha_{20} x^2 + \alpha_{11} xy + \alpha_{02} y^2 + \dots$$

we multiply each side by $(1 + \mu x + \nu y)$, the right-hand side becomes

$$1 + (\alpha_{10} + \mu)x + (\alpha_{01} + \nu)y + \dots + (\alpha_{pq} + \mu \alpha_{p-1, q} + \nu \alpha_{p, q-1}) x^p y^q + \dots$$

hence any rational integral function of the coefficients $\alpha_{10}, \alpha_{01}, \dots, \alpha_{pq}, \dots$ say $f(\alpha_{10}, \alpha_{01}, \dots) \equiv f$ is converted into

$$\frac{\exp(\mu d_{10} + \nu d_{01}) f}{\exp(\mu d_{10} + \nu d_{01})}$$

$$\text{where } d_{10} = \sum \alpha_{p-1, q} \frac{d}{d\alpha_{pq}}, \quad d_{01} = \sum \alpha_{p, q-1} \frac{d}{d\alpha_{pq}}$$

The rule over \exp will serve to denote that $\mu d_{10} + \nu d_{01}$ is to be raised to the various powers symbolically as in Taylor's theorem.

Writing

$$D_{pq} = \frac{1}{p!q!} \frac{d^p d^q}{d\alpha^p d\alpha^q}$$

$$\overline{\exp(\mu d_{10} + \nu d_{01})} = (1 + \mu D_{10} + \nu D_{01} + \dots + \mu^p \nu^q D_{pq} + \dots) f$$

now, since the introduction of the new quantities μ, ν results in the addition to the function $(\overline{p_1 q_1 p_2 q_2 p_3 q_3 \dots})$ of the new terms

$$\mu^{p_1} \nu^{q_1} (\overline{p_1 q_1 p_2 q_2 p_3 q_3 \dots}) + \mu^{p_2} \nu^{q_2} (\overline{p_1 q_1 p_2 q_2 p_3 q_3 \dots}) + \mu^{p_3} \nu^{q_3} (\overline{p_1 q_1 p_2 q_2 p_3 q_3 \dots}) + \dots$$

we find

$$D_{p_1 q_1} (\overline{p_1 q_1 p_2 q_2 p_3 q_3 \dots}) = (\overline{p_2 q_2 p_3 q_3 \dots});$$

and thence

$$D_{p_1 q_1} D_{p_2 q_2} D_{p_3 q_3} \dots (\overline{p_1 q_1 p_2 q_2 p_3 q_3 \dots}) = 1;$$

while $D_{rs} f = 0$ unless the part rs is involved in f . We may then state that D_{pq} is an operation which obliterates one part pq when such part is present, but in the contrary case causes the function to vanish. From the above D_{pq} is an operator of order pq , but it is convenient for some purposes to obtain its expression in the form of a number of terms, each of which denotes pq successive linear operations; to accomplish this write

$$d_{pq} = \sum \alpha_{rs} \frac{d}{d\alpha_{p+r, q+s}}$$

and note the general result.†

$$\overline{\exp(\mu_{10} d_{10} + \mu_{01} d_{01} + \dots + \mu_{pq} d_{pq} + \dots)} = \exp(M_{10} d_{10} + M_{01} d_{01} + \dots + M_{pq} d_{pq} + \dots);$$

where the multiplications on the left- and right-hand sides of the

† Phil. Trans. R. S. London, 1890, p. 490.

equation are symbolic and unsymbolic respectively, provided that m_{pq}, M_{pq} are quantities which satisfy the relation

$$\begin{aligned} \exp(M_{10}\xi + M_{01}\eta + \dots + M_{pq}\xi^p\eta^q + \dots) \\ = 1 + m_{10}\xi + m_{01}\eta + \dots + m_{pq}\xi^p\eta^q + \dots; \end{aligned}$$

where ξ, η are undetermined algebraic quantities. In the present particular case putting $m_{10} = \mu, m_{01} = \nu$ and $m_{pq} = 0$ otherwise

$$M_{10}\xi + M_{01}\eta + \dots + M_{pq}\xi^p\eta^q + \dots = \log(1 + \mu\xi + \nu\eta)$$

or

$$M_{pq} = (-)^{p+q-1} \frac{(p+q-1)!}{p!q!} \mu^p \nu^q;$$

and the result is thus

$$\begin{aligned} \exp(\mu d_{10} + \nu d_{01}) \\ = \exp\left\{\mu d_{10} + \nu d_{01} - \frac{1}{2}(\mu^2 d_{20} + 2\mu\nu d_{11} + \nu^2 d_{02}) + \dots\right\} \\ = 1 + \mu D_{10} + \nu D_{01} + \dots + \mu^p \nu^q D_{pq} + \dots; \end{aligned}$$

and thence

$$\begin{aligned} \mu d_{10} + \nu d_{01} - \frac{1}{2}(\mu^2 d_{20} + 2\mu\nu d_{11} + \nu^2 d_{02}) + \dots \\ = \log(1 + \mu D_{10} + \nu D_{01} + \dots + \mu^p \nu^q D_{pq} + \dots). \end{aligned}$$

From these formulae we derive two important relations, viz. :-

$$\begin{aligned} (-)^{p+q-1} \frac{(p+q-1)!}{p!q!} d_{pq} &= \sum_{\pi} (-)^{\Sigma\pi-1} \frac{(\Sigma\pi-1)!}{\pi_1! \pi_2! \dots} D_{p_1 q_1}^{\pi_1} D_{p_2 q_2}^{\pi_2} \dots, \\ (-)^{p+q-1} D_{pq} &= \sum_{\pi} \left\{ \frac{(p_1+q_1-1)!}{p_1! q_1!} \right\}^{\pi_1} \left\{ \frac{(p_2+q_2-1)!}{p_2! q_2!} \right\}^{\pi_2} \dots \\ &\quad \dots \frac{(-)^{\Sigma\pi-1}}{\pi_1! \pi_2! \dots} d_{p_1 q_1}^{\pi_1} d_{p_2 q_2}^{\pi_2} \dots, \end{aligned}$$

the last written relation having, in regard to each term on the right-hand side, to do with $\Sigma\pi$ successive linear operations. Recalling the formulae above which connect s_{pq} and a_{pq} , we see that d_{pq} and D_{pq} are in correlation with these quantities respectively, and may be said to be operations which correspond to the partitions $(pq), (10^p 01^q)$ respectively. We might conjecture from this observation that every partition is in correspondence with some operation; this is found to be the case, and it has been shown (*loc. cit.* p. 493) that the operation

$$\frac{1}{\pi_1!} \frac{1}{\pi_2!} \dots d_{p_1 q_1}^{\pi_1} d_{p_2 q_2}^{\pi_2} \dots \quad (\text{multiplication symbolic})$$

corresponds to the partition $(p_1 q_1 \pi_1 p_2 q_2 \pi_2 \dots)$. The partitions being taken as denoting symmetric functions we have complete correspondence between the algebras of quantity and operation, and from any algebraic formula we can at once write down an operation formula. This fact is of extreme importance in the theory of algebraic forms, and is easily representable whatever be the number of the systems of quantities.

We may remark the particular result

$$(-)^{p+q-1} \frac{(p+q-1)!}{p!q!} d_{pq} s_{pq} = D_{pq}(\overline{pq}) = 1;$$

d_{pq} causes every other single part function to vanish, and must cause any monomial function to vanish which does not comprise one of the partitions of the biweight pq amongst its parts. Since

$$d_{pq} = (-)^{p+q-1} \frac{(p+q-1)!}{p!q!} \frac{d}{ds_{pq}},$$

the solutions of the partial differential equation $d_{pq} = 0$ are the single bipart forms, omitting s_{pq} , and we have seen that the solutions of $D_{pq} = 0$ are those monomial functions in which the part \overline{pq} is absent.

One more relation is easily obtained, viz. :-

$$\frac{d}{da_{pq}} = d_{pq} - h_{10} d_{p+1, q} - h_{01} d_{p, q+1} + \dots + (-)^{r+s} h_{rs} d_{p+r, q+s} + \dots$$

Theory of Three Identities.—Let

$$1 + a_{10}x + a_{01}y + \dots + a_{pq}x^p y^q + \dots \quad (\text{I.})$$

$$= (1 + \alpha_1 x + \beta_1 y)(1 + \alpha_2 x + \beta_2 y) \dots$$

$$1 + b_{10}x + b_{01}y + \dots + b_{pq}x^p y^q + \dots \quad (\text{II.})$$

$$= (1 + \alpha_1^{(1)}x + \beta_1^{(1)}y)(1 + \alpha_2^{(1)}x + \beta_2^{(1)}y) \dots$$

$$1 + c_{10}x + c_{01}y + \dots + c_{pq}x^p y^q + \dots \quad (\text{III.})$$

$$= (1 + \alpha_1^{(2)}x + \beta_1^{(2)}y)(1 + \alpha_2^{(2)}x + \beta_2^{(2)}y) \dots$$

wherein x and y are to be regarded as undetermined quantities, and the identities as merely expressing relations between the coefficients on the left and the quantities α, β on the right. Assume the coefficients and quantities in the identities I. and II. to be given, and the coefficients in III. to be then determined by

$$\begin{aligned} 1 + c_{10}x + c_{01}y + \dots + c_{pq}x^p y^q + \dots \\ = \Pi(1 + \alpha_s b_{10}x + \beta_s b_{01}y + \dots + \alpha_s^p \beta_s^q b_{pq}x^p y^q + \dots), \end{aligned}$$

ξ and η being undetermined quantities.

This assumes that the coefficients c_{pq} of III. are certain functions of the quantities and coefficients of I. and II. Denoting symmetric functions of the quantities in I., II., and III. by partitions in brackets $(), ()_1, ()_2$ respectively, we find that the assumed relation gives—

$$\begin{aligned} c_{10} &= (\overline{10})b_{10}, \\ c_{01} &= (\overline{01})b_{01}, \\ c_{20} &= (\overline{20})b_{20} + (\overline{10^2})b_{10}^2, \\ c_{11} &= (\overline{11})b_{11} + (\overline{10 \ 01})b_{10}b_{01}, \\ c_{21} &= (\overline{21})b_{21} + (\overline{20 \ 01})b_{20}b_{01} + (\overline{11 \ 10})b_{11}b_{10} + (\overline{10^2 \ 01})b_{10}^2b_{01}, \\ &\quad \&c. \end{aligned}$$

and generally, in the expression of c_{pq} , every symmetric function of biweight pq of the quantities in I. occurs, each attached to the corresponding product of coefficients from the second identity. Now

$$\Pi(1 + \alpha_s b_{10}x + \beta_s b_{01}y + \dots + \alpha_s^p \beta_s^q b_{pq}x^p y^q + \dots)$$

is from II. equal to

$$\Pi \Pi \{1 + \alpha_s a_s^{(1)}x + \beta_s a_s^{(1)}y\},$$

as can be seen by putting $x = \alpha_s \xi, y = \beta_s \eta$. Hence, from the assumed relation and III.,

$$\Sigma \log \{1 + \alpha_s^{(2)} \xi + \beta_s^{(2)} \eta\} = \Sigma \Sigma \log \{1 + \alpha_s a_s^{(1)} \xi + \beta_s a_s^{(1)} \eta\};$$

and now, expanding and equating coefficients of $\xi^p \eta^q$,

$$(\overline{pq})_2 = (\overline{pq})(\overline{pq})_1,$$

a simple and important consequence of the assumed relation. It shows that the relation in question is unaltered by interchange of the quantities in I. and II. in such wise that α_s and $\alpha_s^{(1)}$ and also β_s and $\beta_s^{(1)}$ are transposed.

Let the operations d_{pq}, D_{pq} refer to I., and the corresponding operations of II. and III. be denoted by the same symbols with the addition of single and double dashes respectively. Write the assumed relation in the abbreviated form

$$U = u_{\alpha_1 \beta_1} u_{\alpha_2 \beta_2} u_{\alpha_3 \beta_3} \dots,$$

then

$$d'_{pq} U = (d'_{pq} u_{\alpha_1 \beta_1}) u_{\alpha_2 \beta_2} u_{\alpha_3 \beta_3} \dots + \dots,$$

and

$$d'_{pq} = \frac{d}{db_{pq}} + b_{10} \frac{d}{db_{p+1, q}} + b_{01} \frac{d}{db_{p, q+1}} + \dots,$$

when performed upon $u_{\alpha_s \beta_s}$, gives

$$d'_{pq} u_{\alpha_s \beta_s} = \alpha_s^p \beta_s^q \xi^p \eta^q u_{\alpha_s \beta_s};$$

hence

$$d'_{pq} U = (\overline{pq}) \xi^p \eta^q U,$$

and, replacing U by its expression,

$$d'_{pq} c_{pq} = (\overline{pq}), \text{ and in general}$$

$$d'_{pq} c_{rs} = (\overline{pq}) c_{r-p, s-q};$$

whence, regarding the coefficients b_{pq} as functions of the coefficients c_{pq} only,

$$d'_{pq} = \Sigma (d'_{pq} c_{rs}) \frac{d}{dc_{rs}} = (\overline{pq}) d''_{pq}.$$

In a precisely similar manner $d'_{pq} = (\overline{pq})_1 d''_{pq}$, and making use of the established relation $(\overline{pq})_2 = (\overline{pq})(\overline{pq})_1$,

$$(\overline{pq})_2 d''_{pq} = (\overline{pq})_1 d'_{pq} = (\overline{pq}) d'_{pq}.$$

As a consequence of this, if we regard the assumed relation as defining a transformation of the quantities in III. into either of the sets of quantities occurring in I. and II., the operation $(\overline{pq})_2 d''_{pq}$ is an invariant. We can now derive relations between

the operations $D_{pq}, D'_{pq}, D''_{pq}$. For

$$\begin{aligned} \xi d'_{10} + \eta d'_{01} - \frac{1}{2}(\xi^2 d'_{20} + 2\xi\eta d'_{11} + \eta^2 d'_{02}) + \dots \\ = \xi(\overline{10})d''_{10} + \eta(\overline{01})d''_{01} - \frac{1}{2}\{\xi^2(\overline{20})d''_{20} + 2\xi\eta(\overline{11})d''_{11} + \eta^2(\overline{02})d''_{02}\} + \dots, \end{aligned}$$

and this leads to

$$\begin{aligned} \log(1 + \xi D'_{10} + \eta D'_{01} + \dots + \xi^p \eta^q D'_{pq} + \dots) \\ = \Sigma \log(1 + \xi \alpha_s D''_{10} + \eta \beta_s D''_{01} + \dots + \xi^p \eta^q \alpha_s^p \beta_s^q D''_{pq} + \dots); \end{aligned}$$

and thus to

$$\begin{aligned} 1 + \xi D'_{10} + \eta D'_{01} + \dots + \xi^p \eta^q D'_{pq} + \dots \\ = \Pi(1 + \xi \alpha_s D''_{10} + \eta \beta_s D''_{01} + \dots + \xi^p \eta^q \alpha_s^p \beta_s^q D''_{pq} + \dots); \end{aligned}$$

and this, when compared with the assumed relation, establishes that in any formula connecting the coefficients c_{pq} and b_{pq} , we are at liberty to substitute D_{pq} for c_{pq} and D'_{pq} for b_{pq} ; we thus obtain a corresponding operator relation; further, it is similarly proved that, in any relation connecting the quantities c_{pq} and a_{pq} , we may substitute D_{pq} for c_{pq} and D''_{pq} for a_{pq} .

First Law of Symmetry.—We are now in a position to establish certain laws of symmetry which appertain to the systems of algebraic forms under consideration. The relation $(\overline{pq})_2 = (\overline{pq})_1$ (\overline{pq}) shows that any symmetric function in brackets ()₂ may be expressed as a linear function of products, each of which is a function ()₁ multiplied by a function (), and that, moreover, such expression is symmetrical in regard to the brackets ()₁ and ().

Hence we may write

$$= \dots + J(\overline{a_1 b_1^{a_1} a_2 b_2^{a_2} \dots})_1 (\overline{p_1 q_1^{m_1} p_2 q_2^{m_2} \dots})_2 + J(\overline{a_1 b_1^{a_1} a_2 b_2^{a_2} \dots})_2 (\overline{p_1 q_1^{m_1} p_2 q_2^{m_2} \dots})_1 + \dots \quad (A)$$

Moreover, any product of the coefficients c_{pq} can be expressed as a linear function of terms, each of which contains a monomial function of the quantities $\alpha_1, \beta_1, \alpha_2, \beta_2, \dots$ and a product of coefficients b_{pq} , so that we may assume

$$c_{p_1 q_1}^{\pi_1} c_{p_2 q_2}^{\pi_2} \dots = \dots + L(\overline{a_1 b_1^{a_1} a_2 b_2^{a_2} \dots}) b_{r_1 s_1}^{\rho_1} b_{r_2 s_2}^{\rho_2} \dots + \dots \quad (B)$$

$$c_{a_1 b_1}^{\alpha_1} c_{a_2 b_2}^{\alpha_2} \dots = \dots + M(\overline{p_1 q_1^{m_1} p_2 q_2^{m_2} \dots}) b_{r_1 s_1}^{\rho_1} b_{r_2 s_2}^{\rho_2} \dots + \dots \quad (C)$$

and it will appear that $L=M$; for from (B) can be derived the operator relation

$$D'_{p_1 q_1}^{\pi_1} D'_{p_2 q_2}^{\pi_2} \dots = \dots + L(\overline{a_1 b_1^{a_1} a_2 b_2^{a_2} \dots}) D_{r_1 s_1}^{\rho_1} D_{r_2 s_2}^{\rho_2} \dots + \dots,$$

and performing each side of this equation upon the opposite side of equation (A) we obtain, after cancelling $(\overline{a_1 b_1^{a_1} a_2 b_2^{a_2} \dots})$,

$$LD_{r_1 s_1}^{\rho_1} D_{r_2 s_2}^{\rho_2} \dots (\overline{r_1 s_1^{\rho_1} r_2 s_2^{\rho_2} \dots})_2 = JD'_{p_1 q_1}^{\pi_1} D'_{p_2 q_2}^{\pi_2} \dots (\overline{p_1 q_1^{m_1} p_2 q_2^{m_2} \dots})_1$$

or

$$L=J.$$

By a similar process, in which equation (C) replaces (B), we find $M=J$ and hence $L=M$ and the equations (B) and (C) indicate with $L=M$ a law of symmetry. We may say that in (B) the interchange of the partitions $(\overline{p_1 q_1^{m_1} p_2 q_2^{m_2} \dots})$, $(\overline{a_1 b_1^{a_1} a_2 b_2^{a_2} \dots})$ leaves the number L unchanged. To explain the nature of the theorem that has been established, recourse must be had to the notion of a separation of a partition of given specification; the definitions of these terms have been given above in respect of a single system of quantities and the analogous definitions, in respect of several systems, will be easily understood without further remarks. Writing the relation (B) in the form

$$c_{p_1 q_1}^{\pi_1} c_{p_2 q_2}^{\pi_2} \dots = \dots + P b_{r_1 s_1}^{\rho_1} b_{r_2 s_2}^{\rho_2} \dots + \dots$$

where P denotes the complete cofactor of $b_{r_1 s_1}^{\rho_1} b_{r_2 s_2}^{\rho_2} \dots$ we may state that P is a linear function of symmetric function products each of which is a separation of

$$(\overline{r_1 s_1^{\rho_1} r_2 s_2^{\rho_2} \dots}),$$

and has a specification

$$(\overline{p_1 q_1^{m_1} p_2 q_2^{m_2} \dots}).$$

This appears at once by actually forming the product $c_{p_1 q_1}^{\pi_1} c_{p_2 q_2}^{\pi_2} \dots$ from the separate expressions of $c_{p_1 q_1}, c_{p_2 q_2}, \dots$. Let $\theta_1, \theta_2, \dots, \theta_k$ be the different specifications which appertain to the separations of $(\overline{r_1 s_1^{\rho_1} r_2 s_2^{\rho_2} \dots})$ and let P_θ denote the symmetric function product, of specification θ , above alluded to. It may be seen that when $P_{\theta_1}, P_{\theta_2}, \dots, P_{\theta_k}$ are multiplied out, so as to be exhibited as a linear function of monomial functions, the partitions of the latter are all drawn from the series $\theta_1, \theta_2, \dots, \theta_k$ and we may write

$$P_{\theta_1} = m_{11}\theta_1 + m_{12}\theta_2 + \dots + m_{1k}\theta_k,$$

$$P_{\theta_2} = m_{21}\theta_1 + m_{22}\theta_2 + \dots + m_{2k}\theta_k,$$

$$P_{\theta_k} = m_{k1}\theta_1 + m_{k2}\theta_2 + \dots + m_{kk}\theta_k,$$

the quantities m being numbers.

The law of symmetry, that has been found, may now be stated in the form

$$m_{rs} = m_{sr};$$

viz., the determinant of the above relations is symmetrical. We may say, in regard to any monomial function $(\overline{r_1 s_1^{\rho_1} r_2 s_2^{\rho_2} \dots})$, that if $\theta_1, \theta_2, \dots, \theta_k$ be the monomial functions, whose partitions are the specifications of the various separations, the coefficients of the

monomial θ_s , in the development of the assemblage of separations P_{θ_s} , is equal to the coefficients of the monomial θ_r , in the development of P_{θ_r} .

By solving k linear equations we obtain

$$\theta_1 = \mu_{11}P_{\theta_1} + \mu_{12}P_{\theta_2} + \dots + \mu_{1k}P_{\theta_k},$$

$$\theta_2 = \mu_{21}P_{\theta_1} + \mu_{22}P_{\theta_2} + \dots + \mu_{2k}P_{\theta_k},$$

$$\theta_k = \mu_{k1}P_{\theta_1} + \mu_{k2}P_{\theta_2} + \dots + \mu_{kk}P_{\theta_k},$$

and the determinant of this system is also symmetrical since $\mu_{rs} = \mu_{sr}$ is a necessary consequence of $m_{rs} = m_{sr}$. We can evidently form two symmetrical tables in connexion with every partition of a multipartite number.

The last system of equations involves an important theory of expressibility; for any one of the monomial functions θ is expressed by a partition which is the specification of some separation of

$$(\overline{r_1 s_1^{\rho_1} r_2 s_2^{\rho_2} \dots}),$$

and this implies that the parts of the partition of θ can be partitioned into parts the aggregate of which is identical with the parts of $(\overline{r_1 s_1^{\rho_1} r_2 s_2^{\rho_2} \dots})$. Hence the *theorem of expressibility*. "If the parts of the partition of a monomial function θ be partitioned in any manner into parts, which when all assembled in a single bracket are represented by $(\overline{r_1 s_1^{\rho_1} r_2 s_2^{\rho_2} \dots})$, the symmetric function θ is expressible as a linear function of assemblages of separations of the function

$$(\overline{r_1 s_1^{\rho_1} r_2 s_2^{\rho_2} \dots})."$$

We may write the relation $(\overline{pq})_2 = (\overline{pq})(\overline{pq})_1$ in the form:—

$$\sum_{\pi} (-)^{\Sigma \pi - 1} \frac{(\Sigma \pi - 1)!}{\pi_1! \pi_2! \dots} c_{p_1 q_1}^{\pi_1} c_{p_2 q_2}^{\pi_2} \dots$$

$$= (\overline{pq}) \sum_{\pi} (-)^{\Sigma \pi - 1} \frac{(\Sigma \pi - 1)!}{\pi_1! \pi_2! \dots} b_{p_1 q_1}^{\pi_1} b_{p_2 q_2}^{\pi_2} \dots$$

If we express the quantities c_{pq} in terms of the quantities b_{pq} and $\alpha_1, \beta_1, \alpha_2, \beta_2, \dots$, the symmetric function products which multiply $b_{p_1 q_1}^{\pi_1} b_{p_2 q_2}^{\pi_2} \dots$ on the left will be, all of them, necessarily separations of $(\overline{p_1 q_1^{m_1} p_2 q_2^{m_2} \dots})$, and the result of comparing the cofactors of $b_{p_1 q_1}^{\pi_1} b_{p_2 q_2}^{\pi_2} \dots$, on the two sides, will be the expression of (\overline{pq}) by means of separations of $(\overline{p_1 q_1^{m_1} p_2 q_2^{m_2} \dots})$. Let

$$(J_1)^{j_1} (J_2)^{j_2} \dots$$

be any separation of a given partition of (\overline{pq}) ; the comparison yields the result

$$(-)^{\Sigma \pi - 1} \frac{(\Sigma \pi - 1)!}{\pi_1! \pi_2! \dots} (\overline{pq}) = \sum_j (-)^{\Sigma j - 1} \frac{(\Sigma j - 1)!}{j_1! j_2! \dots} (J_1)^{j_1} (J_2)^{j_2} \dots,$$

the summation, on the right, having reference to every separation of the given partition of (\overline{pq}) . This result, when applied to one part symmetric functions of n systems of quantities, is the furthest generalization of Waring's formula connected with sums of powers that has yet been made. The inverse formula, for the expression of any monomial function by means of one-part functions, may be written

$$(-)^{\Sigma \pi - 1} (\overline{p_1 q_1^{m_1} p_2 q_2^{m_2} \dots})$$

$$= \sum_j (-)^{\Sigma j - 1} \frac{(\Sigma \pi - 1)! (\Sigma \pi_2 - 1)! \dots}{j_1! j_2! \dots \pi_{11}! \pi_{12}! \dots \pi_{21}! \pi_{22}! \dots} s_{j_1}^{j_1} s_{j_2}^{j_2} \dots,$$

where

$$(J_1)^{j_1} (J_2)^{j_2} \dots = (\overline{p_{11} q_{11}^{m_{11}} p_{12} q_{12}^{m_{12}} \dots})^{j_1} (\overline{p_{21} q_{21}^{m_{21}} p_{22} q_{22}^{m_{22}} \dots})^{j_2} \dots$$

is any separation of $(\overline{p_1 q_1^{m_1} p_2 q_2^{m_2} \dots})$, the summation is in respect of all such separations, and s_j denotes the one part function of the same weight as the monomial (J) .

Second Law of Symmetry.—The operation $\frac{1}{\pi_1! \pi_2! \dots} \frac{d^{\pi_1}}{d a_{p_1 q_1}} \frac{d^{\pi_2}}{d a_{p_2 q_2}} \dots$, the multiplication of linear operations being symbolic, and $(\overline{p_1 q_1^{m_1} p_2 q_2^{m_2} \dots})$ being a partition of (\overline{pq}) , may be said to have the weight \overline{pq} ; if the operand be of the same weight the operator is clearly equivalent to

$$\frac{1}{\pi_1! \pi_2! \dots} \left(\frac{d}{d a_{p_1 q_1}} \right)^{\pi_1} \left(\frac{d}{d a_{p_2 q_2}} \right)^{\pi_2} \dots,$$

and thence

$$\frac{1}{\pi_1! \pi_2! \dots} \frac{d^{\pi_1}}{d a_{p_1 q_1}} \frac{d^{\pi_2}}{d a_{p_2 q_2}} \dots \frac{d^{\pi_1}}{d a_{p_1 q_1}} \frac{d^{\pi_2}}{d a_{p_2 q_2}} \dots = 1.$$

Now, from the three identities I, II, and III, we have

$$(\overline{p_1 q_1^{m_1} p_2 q_2^{m_2} \dots})_2 = \dots + P b_{r_1 s_1}^{\rho_1} b_{r_2 s_2}^{\rho_2} \dots + \dots,$$

and the corresponding operator relation

$$\frac{1}{\pi_1! \pi_2! \dots} d^{\pi_1} d^{\pi_2} \dots = \dots + PD_{\rho_1 q_1}^{\rho_1} D_{\tau_1 s_1}^{\tau_1} \dots + \dots;$$

where P consists entirely of symmetric functions of the quantities appertaining to the first identity. Assuming now a relation

$$(\overline{r_1 s_1^{\rho_1} r_2 s_2^{\rho_2} \dots})_2 = \dots + Q \overline{r_1 s_1^{\rho_1} r_2 s_2^{\rho_2} \dots} + \dots,$$

and employing upon its left-hand side the right-hand side of the operator relation and *vice versa*, we obtain the result P=Q, showing that, in the relation

$$(\overline{p_1 q_1^{\rho_1} p_2 q_2^{\rho_2} \dots})_2 = \dots + P \overline{p_1 q_1^{\rho_1} p_2 q_2^{\rho_2} \dots} + \dots,$$

we are at liberty to interchange the partitions

$$(\overline{p_1 q_1^{\rho_1} p_2 q_2^{\rho_2} \dots}) \text{ and } (\overline{r_1 s_1^{\rho_1} r_2 s_2^{\rho_2} \dots}).$$

Third Law of Symmetry.—From the relation

$$c_{\rho_1 q_1}^{\rho_1} c_{\rho_2 q_2}^{\rho_2} \dots = \dots + L b_{\tau_1 s_1}^{\tau_1} b_{\tau_2 s_2}^{\tau_2} \dots + \dots,$$

to which corresponds

$$D'_{\rho_1 q_1} D'_{\rho_2 q_2} \dots = \dots + L D_{\tau_1 s_1}^{\tau_1} D_{\tau_2 s_2}^{\tau_2} \dots + \dots,$$

we obtain by the usual process

$$(\overline{r_1 s_1^{\rho_1} r_2 s_2^{\rho_2} \dots}) = \dots + L (\overline{p_1 q_1^{\rho_1} p_2 q_2^{\rho_2} \dots}) + \dots;$$

involving an interesting law of reciprocity which has been discussed in the Memoirs referred to.

Linear Separation Operations.—A monomial function is expressible as a linear function of separations of any one of the partitions obtained by partitionment of its parts (see *ante*). In particular the partition $(\overline{10^p 01^q})$ can be thus obtained, from any monomial of weight pq , and thence we find that the latter is expressible in terms of the elementary functions, since every product of these, of weight pq , is in fact a separation of $(\overline{10^p 01^q})$. The linear operations d_{pq} , as above defined, are suited to operate upon such expressions, but are not at present adapted to operands associated with a separable partition other than $(\overline{10^p 01^q})$. Let the separable partition be

$$(\overline{p_1 q_1^{\rho_1} p_2 q_2^{\rho_2} \dots});$$

and of this let any separation be

$$(J_1)^{\rho_1} (J_2)^{\rho_2} \dots,$$

$(J_1), (J_2), \dots$ being the distinct factors that may occur. Then $d_{rs} = \sum d_{rs}(J) \frac{d}{d(J)}$, the summation being for all the factors (J) that may present themselves.

Let the general expression of (J) be

$$(\overline{10^{\rho_{10} + \sigma_{10}} 01^{\rho_{01} + \sigma_{01}} \dots r_1 s_1^{\rho_{r_1 s_1} + \sigma_{r_1 s_1}} \dots});$$

then, since

$$(-)^{r+s-1} \frac{(r+s-1)!}{r! s!} d_{rs}$$

$$= \sum (-)^{\sum \rho - 1} \frac{(\sum \rho - 1)!}{\rho_{10}! \rho_{01}! \dots \rho_{r_1 s_1}!} D_{10}^{\rho_{10}} D_{01}^{\rho_{01}} \dots D_{r_1 s_1}^{\rho_{r_1 s_1}},$$

we obtain

$$(-)^{r+s-1} \frac{(r+s-1)!}{r! s!} d_{rs}$$

$$= \sum_{\rho} \sum_{\sigma} (-)^{\sum \rho - 1} \frac{(\sum \rho - 1)!}{\rho_{10}! \rho_{01}! \dots \rho_{r_1 s_1}!} (\overline{10^{\sigma_{10}} 01^{\sigma_{01}} \dots r_1 s_1^{\sigma_{r_1 s_1}} \dots}) \frac{d}{d(J)},$$

the summation being in regard to every distinct factor (J) that may present itself in a separation of the given separable partition, and to every partition $(\overline{10^{\sigma_{10}} 01^{\sigma_{01}} \dots})$ of the weight rs of the given linear operator d_{rs} .

Regarding $\rho_{10}, \rho_{01}, \dots$ as constant write

$$\sum_{\sigma} (\overline{10^{\sigma_{10}} 01^{\sigma_{01}} \dots r_1 s_1^{\sigma_{r_1 s_1}} \dots}) \frac{d}{d(J)} = d(\overline{10^{\rho_{10}} 01^{\rho_{01}} \dots r_1 s_1^{\rho_{r_1 s_1}} \dots}),$$

and the operator relation becomes

$$(-)^{r+s-1} \frac{(r+s-1)!}{r! s!} d_{rs}$$

$$= \sum_{\rho} (-)^{\sum \rho - 1} \frac{(\sum \rho - 1)!}{\rho_{10}! \rho_{01}! \dots \rho_{r_1 s_1}!} d(\overline{10^{\rho_{10}} 01^{\rho_{01}} \dots r_1 s_1^{\rho_{r_1 s_1}} \dots}),$$

the summation now being in regard to every partition $(\overline{10^{\rho_{10}} 01^{\rho_{01}} \dots})$ of the weight rs . Observe that d_{rs} is a linear weight operator; that $d(\overline{10^{\rho_{10}} 01^{\rho_{01}} \dots})$ is a linear partition operator; and that we have expressed the weight operator as a linear function of the partition operators of the same weight. Compare

- (i.) the expression of d_{pq} in terms of the operations D_{pq} ;
- (ii.) the expression of (pq) by means of elementary functions. It will be seen that the same law obtains.

Ex. gr. $d_{11} = d(\overline{10 01}) - d(\overline{11})$

$$d_{21} = d(\overline{10^2 01}) - d(\overline{20 01}) - d(\overline{11 10}) + d(\overline{21}),$$

are examples of the expressions of weight linear operators in terms of partition linear operators. The latter have developed expressions such as

$$d(\overline{10}) = \frac{d}{d(10)} + (\overline{10}) \frac{d}{d(10^2)} + (\overline{01}) \frac{d}{d(10 01)} + (\overline{11}) \frac{d}{d(11 10)} + \dots,$$

$$d(\overline{20 01}) = \frac{d}{d(20 01)} + (\overline{10}) \frac{d}{d(20 10 01)} + \dots$$

The alternant ("Combination," "Zusammensetzung"), of any two partition linear operators vanishes, and, as a consequence, if $d(A), d(B)$ be any two operators and ϕ a solution of $d(A)=0, d(B)\phi$ will also be a solution of the same equation. It has also been shown (*loc. cit.*) that if a function, expressed in terms of separations of a given monomial symmetric function, be caused to vanish by any weight operator, every partition operator of the same weight will also cause it to vanish. This is a cardinal theorem appertaining to the expression of any function by means of separations of a given partition.

Ex. gr. Suppose it requisite to express the function $(\overline{31 01})$ by means of separations of the function $(\overline{21 10 01})$; the "law of expressibility" (*ante*) shows this to be possible, because $(\overline{21 01})$ is a partition of $(\overline{31})$. Assume

$$(\overline{31 01}) = A(\overline{21 10})(\overline{01}) + B(\overline{21 01})(\overline{10}) + C(\overline{10 01})(\overline{21}) + D(\overline{21 10 01}),$$

since the terms $(\overline{21})(\overline{10})(\overline{01})$ clearly cannot present itself. d_{31}, d_{01}, d_{32} do not make $(\overline{31 01})$ vanish, because $(\overline{31 01})$ involves partitions of $\overline{31}, \overline{01}$, and $\overline{32}$; but every other weight operator makes it vanish. Selecting d_{10} and d_{21} we may make further selection of the partition operators $d(10)$ and $d(21)$. Operating then with

$$\frac{d}{d(10)} + (\overline{01}) \frac{d}{d(10 01)} + (\overline{21}) \frac{d}{d(21 10)} + (\overline{21 01}) \frac{d}{d(21 10 01)},$$

and with

$$\frac{d}{d(21)} + (\overline{10}) \frac{d}{d(21 10)} + (\overline{01}) \frac{d}{d(21 01)} + (\overline{10 01}) \frac{d}{d(21 10 01)},$$

we find $A + C = B + D = C + D = A + B = 0$, and thence

$$(\overline{31 01}) = A \{ (\overline{21 10})(\overline{01}) - (\overline{21 01})(\overline{10}) - (\overline{10 01})(\overline{21}) + (\overline{21 10 01}) \}.$$

There are many ways of showing that $A = -\frac{1}{2}$; perhaps the most instructive is to make use of the relation $d_{31} = \dots - D_{31} + \dots = \dots + d(\overline{21 10}) + \dots$; and, performing $-D_{31}$ and $d(\overline{21 10})$ on opposite sides,

$$-(\overline{01}) = A \{ (\overline{01}) + (\overline{01}) \} \text{ or } A = -\frac{1}{2}.$$

It has been seen that a generalization has been made from a weight operator d_{pq} to a partition operator. The same thing obtains with respect to the obliterating operator D_{pq} . In the case of a single system of quantities it was established that D_p is performed upon a product of monomial functions through its various partitions; we have, in fact, to pick out all partitions of p in all possible ways from the given product, taking one part only from each factor of the product; the component operation associated with the partition $(p_1^{\rho_1} p_2^{\rho_2} \dots)$ of p we may appropriately denote by

$$D(p_1^{\rho_1} p_2^{\rho_2} \dots).$$

So similarly, in respect of several systems, we have the weight operator D_{pq} and the partition operator

$$D(\overline{p_1 q_1^{\rho_1} p_2 q_2^{\rho_2} \dots});$$

and we have the equivalence

$$D_{pq} = \sum D(\overline{p_1 q_1^{\rho_1} p_2 q_2^{\rho_2} \dots})$$

the summation being for all partitions of the weight (*loc. cit.* § 10).

Ex. gr. $D_{10} = D(\overline{10})$
 $D_{11} = D(\overline{10 01}) + D(\overline{11}).$

The connexion between the weight operators d_{pq}, D_{pq} has been established; the corresponding relations between the partition operators are important. The analogy between quantity and operation must be kept in view; with this object denote by $s(\overline{p_1 q_1^{\rho_1} p_2 q_2^{\rho_2} \dots})$ the expression of s_{pq} by means of separations of $(\overline{p_1 q_1^{\rho_1} p_2 q_2^{\rho_2} \dots})$, and by S_{pq} the sum of all the monomial symmetric functions of weight pq . S_{pq} differs from h_{pq} as will be seen

by recalling the definition of h_{pq} . From a previous result we may write

$$\sum_{\pi} \frac{(-)^{\Sigma\pi-1} (\Sigma\pi-1)!}{\pi_1! \pi_2! \dots} s(\overline{p_1 q_1}^{\pi_1} \overline{p_2 q_2}^{\pi_2} \dots)$$

$$= \sum_{\pi} \frac{(-)^{\Sigma\pi-1} (\Sigma\pi-1)!}{\pi_1! \pi_2! \dots} S_{p_1 q_1}^{\pi_1} S_{p_2 q_2}^{\pi_2} \dots$$

which must be compared with

$$\sum_{\pi} \frac{(-)^{\Sigma\pi-1} (\Sigma\pi-1)!}{\pi_1! \pi_2! \dots} d(\overline{p_1 q_1}^{\pi_1} \overline{p_2 q_2}^{\pi_2} \dots)$$

$$= \sum_{\pi} \frac{(-)^{\Sigma\pi-1} (\Sigma\pi-1)!}{\pi_1! \pi_2! \dots} D_{p_1 q_1}^{\pi_1} D_{p_2 q_2}^{\pi_2} \dots$$

Now, just as

$$S_{pq} = \Sigma(\overline{p_1 q_1}^{\pi_1} \overline{p_2 q_2}^{\pi_2} \dots),$$

so

$$D_{pq} = \Sigma D(\overline{p_1 q_1}^{\pi_1} \overline{p_2 q_2}^{\pi_2} \dots),$$

and substituting for $S_{p_1 q_1}, S_{p_2 q_2}, \dots$ their partition expressions we obtain, from the quantity relation, the important formula

$$\frac{(-)^{\Sigma\pi-1} (\Sigma\pi-1)!}{\pi_1! \pi_2! \dots} s(\overline{p_1 q_1}^{\pi_1} \overline{p_2 q_2}^{\pi_2} \dots)$$

$$= \sum_j \frac{(-)^{\Sigma j-1} (\Sigma j-1)!}{j_1! j_2! \dots} (J_1)^{j_1} (J_2)^{j_2} \dots,$$

where $(J_1)^{j_1} (J_2)^{j_2} \dots$ is a separation of $(\overline{p_1 q_1}^{\pi_1} \overline{p_2 q_2}^{\pi_2} \dots)$; so in the operator relation, by substituting for the weight operators their expressions in terms of partition operators, we obtain the new formula,

$$\frac{(-)^{\Sigma\pi-1} (\Sigma\pi-1)!}{\pi_1! \pi_2! \dots} d(\overline{p_1 q_1}^{\pi_1} \overline{p_2 q_2}^{\pi_2} \dots)$$

$$= \sum_j \frac{(-)^{\Sigma j-1} (\Sigma j-1)!}{j_1! j_2! \dots} D^{j_1} (J_1) D^{j_2} (J_2) \dots,$$

$D(J_1), D(J_2), \dots$ being partition D operators.

Reversing the two formulae we obtain

$$\frac{(-)^{\Sigma\pi-1} (\overline{p_1 q_1}^{\pi_1} \overline{p_2 q_2}^{\pi_2} \dots)}{(\Sigma\pi-1)! (\Sigma\pi_2-1)! \dots} s^{j_1} (J_1) s^{j_2} (J_2) \dots;$$

$$\frac{(-)^{\Sigma\pi-1} D(\overline{p_1 q_1}^{\pi_1} \overline{p_2 q_2}^{\pi_2} \dots)}{(\Sigma\pi_1-1)! (\Sigma\pi_2-1)! \dots} d^{j_1} (J_1) d^{j_2} (J_2) \dots;$$

where $(J_1) = (\overline{p_{11} q_{11}}^{\pi_{11}} \overline{p_{12} q_{12}}^{\pi_{12}} \dots), (J_2) = (\overline{p_{21} q_{21}}^{\pi_{21}} \overline{p_{22} q_{22}}^{\pi_{22}} \dots), \&c.$

We have thus complete correspondence between the algebras of quantity and differential operation.

Observe the particular results

$$D(\overline{p_1 q_1}^{\pi_1} \overline{p_2 q_2}^{\pi_2} \dots) s_{p_1 q_1}^{\pi_1} s_{p_2 q_2}^{\pi_2} \dots = 1,$$

$$\frac{1}{j_1! j_2! \dots} d^{j_1} (J_1) d^{j_2} (J_2) \dots (J_1)^{j_1} (J_2)^{j_2} \dots = 1.$$

III. THE THEORY OF BINARY FORMS.

A binary form of order n is a homogeneous polynomial of the n th degree in two variables. It may be written in the form

$$ax_1^n + bx_1^{n-1}x_2 + cx_1^{n-2}x_2^2 + \dots;$$

or in the form

$$ax_1^n + \binom{n}{1}bx_1^{n-1}x_2 + \binom{n}{2}cx_1^{n-2}x_2^2 + \dots,$$

which Cayley denotes by

$$(a, b, c, \dots)(x_1, x_2)^n$$

$\binom{n}{1}, \binom{n}{2}, \dots$ being a notation for the successive binomial coefficients $n, \frac{1}{2}n(n-1), \dots$. Other forms are

$$ax_1^n + nbx_1^{n-1}x_2 + n(n-1)cx_1^{n-2}x_2^2 + \dots,$$

the binomial coefficients $\binom{n}{s}$ being replaced by $s! \binom{n}{s}$, and

$$ax_1^n + \frac{1}{1!}bx_1^{n-1}x_2 + \frac{1}{2!}cx_1^{n-2}x_2^2 + \dots,$$

the special convenience of which will appear later. For present purposes the form will be written

$$\overline{a_0}x_1^n + \binom{n}{1}\overline{a_1}x_1^{n-1}x_2 + \binom{n}{2}\overline{a_2}x_1^{n-2}x_2^2 + \dots + \overline{a_n}x_2^n,$$

the notation adopted by German writers; the literal coefficients have a rule placed over them to distinguish them from umbral coefficients which are introduced almost at once. The coefficients $\overline{a_0}, \overline{a_1}, \overline{a_2}, \dots, \overline{a_n}$, $n+1$ in number are arbitrary. If the form, sometimes termed a quantic, be equated to zero the $n+1$ coefficients are equivalent to but n , since one can be made unity by division and the equation is to be regarded as one for the determination of the ratio of the variables.

If the variables of the quantic $f(x_1, x_2)$ be subjected to the linear transformation

$$x_1 = a_{11}\xi_1 + a_{12}\xi_2,$$

$$x_2 = a_{21}\xi_1 + a_{22}\xi_2,$$

ξ_1, ξ_2 being new variables replacing x_1, x_2 and the coefficients $a_{11}, a_{12}, a_{21}, a_{22}$, termed the coefficients of substitution (or of transformation), being constants, we arrive at a transformed quantic

$$f(\xi_1, \xi_2) = \overline{a'_0}\xi_1^n + \binom{n}{1}\overline{a'_1}\xi_1^{n-1}\xi_2 + \binom{n}{2}\overline{a'_2}\xi_1^{n-2}\xi_2^2 + \dots + \overline{a'_n}\xi_2^n$$

in the new variables which is of the same order as the original quantic; the new coefficients $\overline{a'_0}, \overline{a'_1}, \overline{a'_2}, \dots, \overline{a'_n}$ are linear functions of the original coefficients, and also linear functions of products, of the coefficients of substitution, of the n th degree.

By solving the equations of transformation we obtain

$$r\xi_1 = a_{22}x_1 - a_{12}x_2,$$

$$r\xi_2 = -a_{21}x_1 + a_{11}x_2,$$

$$\text{where } r = \begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix} = a_{11}a_{22} - a_{12}a_{21};$$

r is termed the determinant of substitution or modulus of transformation; we assume x_1, x_2 to be independents, so that r must differ from zero.

In the theory of forms we seek functions of the coefficients and variables of the original quantic which, save as to a power of the modulus of transformation, are equal to the like functions of the coefficients and variables of the transformed quantic. We may have such a function which does not involve the variables, viz. :—

$$F(\overline{a'_0}, \overline{a'_1}, \overline{a'_2}, \dots, \overline{a'_n}) = r^\lambda F(\overline{a_0}, \overline{a_1}, \overline{a_2}, \dots, \overline{a_n}),$$

the function $F(\overline{a_0}, \overline{a_1}, \overline{a_2}, \dots, \overline{a_n})$ is then said to be an *invariant* of the quantic *quod* linear transformation. If, however, F involve as well the variables, viz. :—

$$F(\overline{a'_0}, \overline{a'_1}, \overline{a'_2}, \dots; \xi_1, \xi_2) = r^\lambda F(\overline{a_0}, \overline{a_1}, \overline{a_2}, \dots; x_1, x_2),$$

the function $F(\overline{a_0}, \overline{a_1}, \overline{a_2}, \dots; x_1, x_2)$ is said to be a *covariant* of the quantic. The expression "invariantive forms" includes both invariants and covariants, and frequently also other analogous forms which will be met with. Occasionally the word "invariantive" includes covariants; when this is so it will be implied by the text. Invariantive forms will be found to be homogeneous functions alike of the coefficients and of the variables. Instead of a single quantic we may have several

$$f(\overline{a_0}, \overline{a_1}, \overline{a_2}, \dots; x_1, x_2), \phi(\overline{b_0}, \overline{b_1}, \overline{b_2}, \dots; x_1, x_2), \dots$$

which have different coefficients, the same variables, and are of the same or different degrees in the variables; we may transform them all by the same substitution, so that they become

$$f(\overline{a'_0}, \overline{a'_1}, \overline{a'_2}, \dots; \xi_1, \xi_2), \phi(\overline{b'_0}, \overline{b'_1}, \overline{b'_2}, \dots; \xi_1, \xi_2), \dots$$

If then we find

$$F(\overline{a'_0}, \overline{a'_1}, \overline{a'_2}, \dots, \overline{b'_0}, \overline{b'_1}, \overline{b'_2}, \dots; \xi_1, \xi_2),$$

$$= r^\lambda F(\overline{a_0}, \overline{a_1}, \overline{a_2}, \dots, \overline{b_0}, \overline{b_1}, \overline{b_2}, \dots; x_1, x_2),$$

the function F , on the right which multiplies r^λ , is said to be a *simultaneous invariant* or covariant of the system of quantics. This notion is fundamental in the present theory because we will find that one of the most valuable artifices for finding invariants of a single quantic is first to find simultaneous invariants of several different quantics, and subsequently to make all the quantics identical. Moreover, instead of having one pair of variables x_1, x_2 we may have several pairs $y_1, y_2; z_1, z_2; \dots$ in

addition, and transform each pair to a new pair by substitutions, having the same coefficients $a_{11}, a_{12}, a_{21}, a_{22}$ and arrive at functions of the original coefficients and variables (of one or more quantities) which possess the above-defined invariant property. A particular quantic of the system may be of the same or different degrees in the pairs of variables which it involves, and these degrees may vary from quantic to quantic of the system. Such quantics have been termed by Cayley *multipartite*.

Symbolic Form.—Restricting consideration, for the present, to binary forms in a single pair of variables, we must introduce the symbolic form of Aronhold, Clebsch, and Gordan; they write the form

$$(a_1x_1 + a_2x_2)^n = a_1^n x_1^n + \binom{n}{1} a_1^{n-1} a_2 x_1^{n-1} x_2 + \dots + a_2^n x_2^n = \bar{a}_x^n$$

wherein a_1, a_2 are umbrae, such that

$$a_1^n, a_1^{n-1} a_2, \dots, a_1 a_2^{n-1}, a_2^n$$

are symbolical representations of the real coefficients $\bar{a}_0, \bar{a}_1, \dots, \bar{a}_{n-1}, \bar{a}_n$, and in general $a_1^{n-k} a_2^k$ is the symbol for \bar{a}_k . If we restrict ourselves to this set of symbols we can uniquely pass from a product of real coefficients to the symbolical representations of such product, but we cannot, uniquely, from the symbols recover the real form. This is clear because we can write

$$\bar{a}_1 \bar{a}_2 = a_1^{n-1} a_2 \cdot a_1^{n-2} a_2^2 = a_1^{2n-3} a_2^3$$

while the same product of umbrae arises from

$$\bar{a}_0 \bar{a}_2 = a_1 \cdot a_1^{n-3} a_2^3 = a_1^{2n-3} a_2^3$$

Hence it becomes necessary to have more than one set of umbrae, so that we may have more than one symbolical representation of the same real coefficients. We consider the quantic to have any number of equivalent representations $a_x^n \equiv b_x^n \equiv c_x^n \equiv \dots$. So that $a_1^{n-k} a_2^k \equiv b_1^{n-k} b_2^k \equiv c_1^{n-k} c_2^k \equiv \dots = \bar{a}_k$; and if we wish to denote, by umbrae, a product of coefficients of degree s we employ s sets of umbrae.

Ex. gr. We write $\bar{a}_1 \bar{a}_2 = a_1^{n-1} a_2 \cdot b_1^{n-2} b_2^2$,

$$\bar{a}_3 = a_1^{n-3} a_2^3 \cdot b_1^{n-3} b_2^3 \cdot c_1^{n-3} c_2^3,$$

and so on whenever we require to represent a product of real coefficients symbolically; we then have a one-to-one correspondence between the products of real coefficients and their symbolical forms. If we have a function of degree s in the coefficients, we may select any s sets of umbrae for use, and having made a selection we may when only one quantic is under consideration at any time permute the sets of umbrae in any manner without altering the real significance of the symbolism. *Ex. gr.* To express the function $\bar{a}_0 \bar{a}_2 - \bar{a}_1^2$, which is the discriminant of the binary quadratic $\bar{a}_0 x_1^2 + 2\bar{a}_1 x_1 x_2 + \bar{a}_2 x_2^2 = a_x^2 = b_x^2$, in a symbolic form we have

$$2(a_0 a_2 - a_1^2) = \bar{a}_0 \bar{a}_2 - \bar{a}_1^2 = \bar{a}_0 a_2 - 2\bar{a}_1 \cdot a_1 = a_1^2 b_1^2 + a_2^2 b_2^2 - 2a_1 a_2 b_1 b_2 = (a_1 b_2 - a_2 b_1)^2.$$

Such an expression as $a_1 b_2 - a_2 b_1$, which is

$$\frac{\partial a_x}{\partial x_1} \frac{\partial b_x}{\partial x_2} - \frac{\partial a_x}{\partial x_2} \frac{\partial b_x}{\partial x_1},$$

is usually written (ab) for brevity; in the same notation the determinant, whose rows are $a_1, a_2, a_3; b_1, b_2, b_3; c_1, c_2, c_3$ respectively, is written (abc) and so on. It should be noticed that the real function denoted by $(ab)^2$ is not the square of a real function denoted by (ab) . For a single quantic of the first order (ab) is the symbol of a function of the coefficients which vanishes identically; thus

$$(ab) = a_1 b_2 - a_2 b_1 = \bar{a}_0 a_1 - \bar{a}_1 a_0 = 0$$

and, indeed, from a remark made above we see that (ab) remains unchanged by interchange of a and b ; but $(ab) = -(ba)$, and these two facts necessitate $(ab) = 0$.

To find the effect of linear transformation on the symbolic form of quantic we will discuss the coefficients $a_{11}, a_{12}, a_{21}, a_{22}$, and employ $\lambda_1, \mu_1, \lambda_2, \mu_2$. For the substitution

$$x_1 = \lambda_1 \xi_1 + \mu_1 \xi_2, \quad x_2 = \lambda_2 \xi_1 + \mu_2 \xi_2,$$

$$\text{of modulus } \begin{vmatrix} \lambda_1 & \mu_1 \\ \lambda_2 & \mu_2 \end{vmatrix} = (\lambda_1 \mu_2 - \lambda_2 \mu_1) = (\lambda \mu),$$

the quadratic form $\bar{a}_0 x_1^2 + 2\bar{a}_1 x_1 x_2 + \bar{a}_2 x_2^2 = a_x^2 = f(x)$, becomes

$$\bar{A}_0 \xi_1^2 + 2\bar{A}_1 \xi_1 \xi_2 + \bar{A}_2 \xi_2^2 = A_\xi^2 = \phi(\xi),$$

where

$$\begin{aligned} \bar{A}_0 &= \bar{a}_0 \lambda_1^2 + 2\bar{a}_1 \lambda_1 \lambda_2 + \bar{a}_2 \lambda_2^2, \\ \bar{A}_1 &= \bar{a}_0 \lambda_1 \mu_1 + \bar{a}_1 (\lambda_1 \mu_2 + \lambda_2 \mu_1) + \bar{a}_2 \lambda_2 \mu_2, \\ \bar{A}_2 &= \bar{a}_0 \mu_1^2 + 2\bar{a}_1 \mu_1 \mu_2 + \bar{a}_2 \mu_2^2. \end{aligned}$$

We pass to the symbolic forms

$$a_x^2 = (a_1 x_1 + a_2 x_2)^2, \quad A_\xi^2 = (A_1 \xi_1 + A_2 \xi_2)^2,$$

by writing for

$$\begin{aligned} \bar{a}_0, \bar{a}_1, \bar{a}_2 & \text{ the symbols } a_1^2, a_1 a_2, a_2^2 \\ \bar{A}_0, \bar{A}_1, \bar{A}_2 & \text{ ,, } A_1^2, A_1 A_2, A_2^2 \end{aligned}$$

and then

$$\bar{A}_0 = a_1^2 \lambda_1^2 + 2a_1 a_2 \lambda_1 \lambda_2 + a_2^2 \lambda_2^2 = (a_1 \lambda_1 + a_2 \lambda_2)^2 = a_\lambda^2,$$

$$\bar{A}_1 = (a_1 \lambda_1 + a_2 \lambda_2)(a_1 \mu_1 + a_2 \mu_2) = a_\lambda a_\mu,$$

$$\bar{A}_2 = (a_1 \mu_1 + a_2 \mu_2)^2 = a_\mu^2;$$

so that

$$A_\xi^2 = a_\lambda^2 \xi_1^2 + 2a_\lambda a_\mu \xi_1 \xi_2 + a_\mu^2 \xi_2^2 = (a_\lambda \xi_1 + a_\mu \xi_2)^2;$$

whence A_1, A_2 become a_λ, a_μ respectively and

$$\phi(\xi) = (a_\lambda \xi_1 + a_\mu \xi_2)^2.$$

The practical result of the transformation is to change the umbrae a_1, a_2 into the umbrae

$$a_\lambda = a_1 \lambda_1 + a_2 \lambda_2, \quad a_\mu = a_1 \mu_1 + a_2 \mu_2$$

respectively.

By similarly transforming the binary n^{ic} form a_x^n we find

$$\bar{A}_0 = (a_1 \lambda_1 + a_2 \lambda_2)^n = a_\lambda^n = A_1^n,$$

$$\bar{A}_1 = (a_1 \lambda_1 + a_2 \lambda_2)^{n-1} (a_1 \mu_1 + a_2 \mu_2) = a_\lambda^{n-1} a_\mu = A_1^{n-1} A_2,$$

$$\bar{A}_k = (a_1 \lambda_1 + a_2 \lambda_2)^{n-k} (a_1 \mu_1 + a_2 \mu_2)^k = a_\lambda^{n-k} a_\mu^k = A_1^{n-k} A_2^k,$$

so that the umbrae A_1, A_2 are a_λ, a_μ respectively.

Theorem.—When the binary form

$$a_x^n = (a_1 x_1 + a_2 x_2)^n,$$

is transformed to

$$A_\xi^n = (A_1 \xi_1 + A_2 \xi_2)^n,$$

by the substitutions

$$x_1 = \lambda_1 \xi_1 + \mu_1 \xi_2, \quad x_2 = \lambda_2 \xi_1 + \mu_2 \xi_2,$$

the umbrae A_1, A_2 are expressed in terms of the umbrae a_1, a_2 by the formulæ

$$A_1 = \lambda_1 a_1 + \lambda_2 a_2, \quad A_2 = \mu_1 a_1 + \mu_2 a_2.$$

We gather that A_1, A_2 are transformed to a_1, a_2 in such wise that the determinant of transformation reads by rows as the original determinant reads by columns, and that the modulus of the transformation is, as before, $(\lambda \mu)$. For this reason the umbrae A_1, A_2 are said to be *contragredient* to a_1, a_2 . If we solve the equations connecting the original and transformed umbrae we find

$$\begin{aligned} (\lambda \mu)(-a_2) &= \lambda_1(-A_2) + \mu_1 A_1, \\ (\lambda \mu)a_1 &= \lambda_2(-A_2) + \mu_2 A_1, \end{aligned}$$

and we find that, except for the factor $(\lambda \mu)$, $-a_2$ and $+a_1$ are transformed to $-A_2$ and $+A_1$ by the same substitutions as a_1 and a_2 are transformed to ξ_1 and ξ_2 . For this reason the umbrae $-a_2, a_1$ are said to be *cogredient* to a_1 and a_2 . We frequently meet with *cogredient* and *contragredient* quantities, and we have in general the following definitions:—(1) "If two equally numerous sets of quantities $x, y, z, \dots, x', y', z', \dots$ are such that whenever one set x, y, z, \dots is expressed in terms of new quantities X, Y, Z, \dots the second set x', y', z', \dots is expressed in terms of other new quantities X', Y', Z', \dots , by the same scheme of linear substitution the two sets are said to be *cogredient* quantities." (2) "Two sets of quantities $x, y, z, \dots; \xi, \eta, \zeta, \dots$ are said to be *contragredient* when the linear substitutions for the first set are

$$\begin{aligned} x &= \lambda_1 X + \mu_1 Y + \nu_1 Z + \dots, \\ y &= \lambda_2 X + \mu_2 Y + \nu_2 Z + \dots, \\ z &= \lambda_3 X + \mu_3 Y + \nu_3 Z + \dots, \end{aligned}$$

and these are associated with the following formulæ appertaining to the second set,

$$\begin{aligned} \xi &= \lambda_1 \xi + \lambda_2 \eta + \lambda_3 \zeta + \dots, \\ \eta &= \mu_1 \xi + \mu_2 \eta + \mu_3 \zeta + \dots, \\ \zeta &= \nu_1 \xi + \nu_2 \eta + \nu_3 \zeta + \dots, \end{aligned}$$

wherein it should be noticed that *new* quantities are expressed in terms of the *old*, as regards the latter set, and not *vice versa*."

Ex. gr. The symbols $\frac{d}{dx}, \frac{d}{dy}, \frac{d}{dz}, \dots$ are *contragredient* with the variables x, y, z, \dots for when

$$(x, y, z, \dots) = (\lambda_1, \mu_1, \nu_1, \dots)(X, Y, Z, \dots),$$

$$\begin{vmatrix} \lambda_1 & \mu_1 & \nu_1 & \dots \\ \lambda_2 & \mu_2 & \nu_2 & \dots \\ \lambda_3 & \mu_3 & \nu_3 & \dots \\ \dots & \dots & \dots & \dots \end{vmatrix}$$

we find

$$\left(\frac{d}{dX} \frac{d}{dY} \frac{d}{dZ} \dots \right) = (\lambda_1, \lambda_1, \lambda_3, \dots) \begin{pmatrix} \frac{d}{dx} & \frac{d}{dy} & \frac{d}{dz} & \dots \\ \mu_1 & \mu_2 & \mu_3 & \dots \\ \nu_1 & \nu_2 & \nu_3 & \dots \\ \dots & \dots & \dots & \dots \end{pmatrix}$$

Observe the notation, which is that introduced by Cayley into the theory of matrices which he himself created.

Just as cogredieny leads to a theory of covariants, so contragredieny leads to a theory of contravariants. If u , a quantic in x, y, z, \dots , be expressed in terms of new variables X, Y, Z, \dots ; and if ξ, η, ζ, \dots be quantities contragredient to x, y, z, \dots ; there are found to exist functions of ξ, η, ζ, \dots , and of the coefficients in u , which need, at most, be multiplied by powers of the modulus to be made equal to the same functions of X, Y, Z, \dots of the transformed coefficients of u ; such functions are called *contravariants* of u . There also exist functions, which involve both sets of variables as well as the coefficients of u , possessing a like property; such have been termed *mixed concomitants*, and they, like contravariants, may appertain as well to a system of forms as to a single form.

As between the original and transformed quantic we have the umbral relations

$$A_1 = \lambda_1 a_1 + \lambda_2 a_2, \quad A_2 = \mu_1 a_1 + \mu_2 a_2,$$

and for a second form

$$B_1 = \lambda_1 b_1 + \lambda_2 b_2, \quad B_2 = \mu_1 b_1 + \mu_2 b_2.$$

The original forms are a_x^n, b_x^n , and we may regard them either as *different forms* or as equivalent representations of the *same form*. In other words, B, b may be regarded as different or alternative symbols to A, a . In either case

$$(AB) = A_1 B_2 - A_2 B_1 = (\lambda \mu)(ab);$$

and, from the definition, (ab) possesses the invariant property. We cannot, however, say that it is an invariant unless it is expressible in terms of the real coefficients. Since $(ab) = a_1 b_2 - a_2 b_1$, that this may be the case each form must be linear; and if the forms be different (ab) is an invariant (simultaneous) of the two forms, its real expression being $\bar{a}_1 \bar{b}_2 - \bar{a}_2 \bar{b}_1$. This will be recognized as the resultant of the two linear forms. If the two linear forms be identical, the umbral sets $a_1, a_2; b_1, b_2$ are alternative, are ultimately put equal to one another and (ab) vanishes. A single linear form has, in fact, no invariant. When either of the forms is of an order higher than the first (ab) , as not being expressible in terms of the actual coefficients of the forms, is not an invariant and has no significance. Introducing now other sets of symbols $C, D, \dots; c, d, \dots$ we may write

$$(AB)^i (AC)^j (BC)^k \dots = (\lambda \mu)^{i+j+k+\dots} (ab)^i (ac)^j (bc)^k \dots,$$

so that the symbolic product

$$(ab)^i (ac)^j (bc)^k \dots,$$

possesses the invariant property. If the forms be all linear and different the function is an invariant, viz., the i^{th} power of that appertaining to a_x and b_x multiplied by the j^{th} power of that appertaining to a_x and c_x multiplied by &c. If any two of the linear forms, say p_x, q_x , be supposed identical, any symbolic expression involving the factor (pq) is zero. Notice, therefore, that the symbolic product $(ab)^i (ac)^j (bc)^k \dots$ may be always viewed as a simultaneous invariant of a number of different linear forms a_x, b_x, c_x, \dots . In order that $(ab)^i (ac)^j (bc)^k \dots$ may be a simultaneous invariant of a number of different forms $a_x^{n_1}, b_x^{n_2}, c_x^{n_3}, \dots$, where n_1, n_2, n_3, \dots may be the same or different, it is necessary that every product of umbræ which arises in the expansion of the symbolic product be of degree n_1 in a_1, a_2 ; in the case of b_1, b_2 of degree n_2 ; in the case of c_1, c_2 of degree n_3 ; and so on. For these only will the symbolic product be replaceable by a linear function of products of real coefficients. Hence the condition is

$$\begin{aligned} i + j + \dots &= n_1, \\ i + k + \dots &= n_2, \\ j + k + \dots &= n_3, \\ &\dots \end{aligned}$$

If the forms $a_x^n, b_x^n, c_x^n, \dots$ be identical the symbols are alternative, and provided that the form does not vanish it denotes an invariant of the single form a_x^n .

There may be a number of forms a_x, b_x, c_x, \dots and we may suppose such identities between the symbols that on the whole only two, three, or more of the sets of umbræ are not equivalent; we will then obtain invariants of two, three, or more sets of binary forms. The symbolic expression of a covariant is equally simple, because we see at once that since $A\xi, B\xi, C\xi, \dots$ are equal to a_x, b_x, c_x, \dots

respectively, the linear forms a_x, b_x, c_x, \dots possess the invariant property, and we may write

$$\begin{aligned} (AB)^i (AC)^j (BC)^k \dots A\xi^p B\xi^q C\xi^r \dots \\ = (\lambda \mu)^{i+j+k+\dots} (ab)^i (ac)^j (bc)^k \dots a_x^p b_x^q c_x^r \dots, \end{aligned}$$

and assert that the symbolic product

$$(ab)^i (ac)^j (bc)^k \dots a_x^p b_x^q c_x^r \dots$$

possesses the invariant property. It is always an invariant or covariant appertaining to a number of different linear forms, and as before it may vanish if two such linear forms be identical. In general it will be simultaneous covariant of the different forms $a_x^{n_1}, b_x^{n_2}, c_x^{n_3}, \dots$ if

$$\begin{aligned} i + j + \dots + p &= n_1, \\ i + k + \dots + q &= n_2, \\ j + k + \dots + r &= n_3, \\ &\dots \end{aligned}$$

It will also be a covariant if the symbolic product be factorizable into portions each of which satisfies these conditions. If the forms be identical the sets of symbols are ultimately equated, and the form, provided it does not vanish, is a covariant of the form a_x^n .

The expression $(ab)^4$ properly appertains to a quartic; for a quadratic it may also be written $(ab)^2 (cd)^2$, and would denote the square of the discriminant to a factor *prés*. For the quartic

$$\begin{aligned} (ab)^4 &= (a_1 b_2 - a_2 b_1)^4 = a_1^4 b_2^4 - 4a_1^3 a_2 b_1 b_2^3 + 6a_1^2 a_2^2 b_1^2 b_2^2 \\ &\quad - 4a_1 a_2^3 b_1^3 b_2 + a_2^4 b_1^4 = \bar{a}_0 \bar{a}_4 - 4\bar{a}_1 \bar{a}_3 + 6\bar{a}_2^2 - 4\bar{a}_1 \bar{a}_3 + \bar{a}_0 \bar{a}_4 \\ &= 2(\bar{a}_0 \bar{a}_4 - 4\bar{a}_1 \bar{a}_3 + 3\bar{a}_2^2), \end{aligned}$$

one of the well-known invariants of the quartic.

For the cubic $(ab)^2 a_x b_x$ is a covariant because each symbol a, b occurs three times; we can first of all find its real expression as a simultaneous covariant of two cubics, and then, by supposing the two cubics to merge into identity, find the expression of the quadratic covariant, of the single cubic, commonly known as the Hessian.

By simple multiplication

$$\begin{aligned} &(\alpha_1^2 b_1 b_2^2 - 2\alpha_1 \alpha_2 b_1^2 b_2 + \alpha_1 \alpha_2^2 b_1^3) \alpha_1^2 \\ &+ (\alpha_1^2 b_2^3 - \alpha_1 \alpha_2^2 b_1^2 b_2 - \alpha_1^2 \alpha_2 b_1 b_2^2 + \alpha_2^3 b_1^3) \alpha_1 \alpha_2 \\ &+ (\alpha_1^2 \alpha_2 b_2^3 - 2\alpha_1 \alpha_2^2 b_1 b_2^2 + \alpha_2^3 b_1^3) \alpha_2^2; \end{aligned}$$

and transforming to the real form,

$$\begin{aligned} &(\alpha_0 b_2 - 2\alpha_1 b_1 + \alpha_2 b_0) \alpha_1^2 + (\alpha_0 b_3 - \alpha_1 b_2 - \alpha_2 b_1 + \alpha_3 b_0) \alpha_1 \alpha_2 \\ &\quad + (\alpha_1 b_3 - 2\alpha_2 b_2 + \alpha_3 b_1) \alpha_2^2, \end{aligned}$$

the simultaneous covariant; and now, putting $b = a$, we obtain twice the Hessian

$$(\alpha_0 \alpha_3 - \alpha_1^2) \alpha_1^2 + (\alpha_1 \alpha_3 - \alpha_1 \alpha_2) \alpha_1 \alpha_2 + (\alpha_1 \alpha_3 - \alpha_2^2) \alpha_2^2.$$

It will be shown later that all invariants, single or simultaneous, are expressible in terms of symbolic products. The degree of the covariant in the coefficients is equal to the number of different symbols a, b, c, \dots that occur in the symbolic expression; the degree in the variables (*i.e.* the order of the covariant) is $\rho + \sigma + \tau + \dots$ and the weight * of the coefficient of the leading term $x_1^{\rho+\sigma+\tau+\dots}$ is equal to $i + j + k + \dots$. It will be apparent that there are four numbers associated with a covariant, viz., the orders of the quantic and covariant, and the degree and weight of the leading coefficient; calling these n, ϵ, θ, w respectively we can see that they are not independent integers, but that they are invariably connected by a certain relation $n\theta - 2w = \epsilon$. For, if $\phi(\bar{a}_0, \dots, \bar{a}_1, \bar{a}_2)$ be a covariant of order ϵ appertaining to a quantic of order n ,

$$\phi(\bar{A}_0, \dots, \bar{\xi}_1, \bar{\xi}_2) = (\lambda \mu)^w \phi(\bar{a}_0, \dots, \lambda_1 \bar{\xi}_1 + \mu_1 \bar{\xi}_2, \lambda_2 \bar{\xi}_1 + \mu_2 \bar{\xi}_2);$$

we find that the left- and right-hand sides are of degrees $n\theta$ and $2w + \epsilon$ respectively in $\lambda_1, \mu_1, \lambda_2, \mu_2$, and thence $n\theta = 2w + 2\epsilon$.

Symbolic Identities.—For the purpose of manipulating symbolic expressions it is necessary to be in possession of certain simple identities which connect certain symbolic products. From the three equations

$$a_x = a_1 x_1 + a_2 x_2, \quad b_x = b_1 x_1 + b_2 x_2, \quad c_x = c_1 x_1 + c_2 x_2,$$

we find by eliminating x_1 and x_2 the relation

$$a_x(bc) + b_x(ca) + c_x(ab) = 0 \quad (I)$$

Introduce now new umbræ \bar{a}_1, \bar{a}_2 and recall that $+ \bar{a}_2, - \bar{a}_1$, are cogredient with x_1 and x_2 . We may in any relation substitute for any pair of quantities any other cogredient pair so that

* The weight of a term $\bar{a}_0^{k_0} \bar{a}_1^{k_1} \dots \bar{a}_n^{k_n}$ is defined as being $k_1 + 2k_2 + \dots + nk_n$.

writing $+d_2, -d_1$ for x_1 and x_2 , and noting that g_x then becomes (gd) , the above-written identity becomes

$$(ad)(bc) + (bd)(ca) + (cd)(ab) = 0 \quad (II.)$$

Similarly in (I.), writing for c_1, c_2 , the cogredient pair $-y_2, +y_1$, we obtain

$$a_x b_y - a_y b_x = (ab)(xy) \quad (III.)$$

Again in (I.), transposing $a_x(bc)$ to the other side and squaring, we obtain

$$2(ac)(bc)a_x b_x = (bc)^2 a_x^2 + (ac)^2 b_x^2 - (ab)^2 c_x^2 \quad (IV.)$$

and herein writing $a_2, -a_1$ for x_1, x_2 ,

$$2(ac)(bc)(ad)(bd) = (bc)^2(ad)^2 + (ac)^2(bd)^2 - (ab)^2(cd)^2 \quad (V.)$$

As an illustration multiply (IV.) throughout by $a_x^{n-2} b_x^{n-2} c_x^{n-2}$ so that each term may denote a covariant of an n^{th} .

$$2(ac)(bc)a_x^{n-1} b_x^{n-1} c_x^{n-1} = (bc)^2 a_x^{n-2} b_x^{n-2} c_x^{n-2} + (ac)^2 a_x^{n-2} b_x^{n-2} c_x^{n-2} - (ab)^2 a_x^{n-2} b_x^{n-2} c_x^{n-2}$$

Each term on the right-hand side may be shown by permutation of a, b, c to be the symbolical representation of the same covariant; they are equivalent symbolic products, and we may accordingly write

$$2(ac)(bc)a_x^{n-1} b_x^{n-1} c_x^{n-2} = (ab)^2 a_x^{n-2} b_x^{n-2} c_x^n$$

a relation which shows that the form on the left is the product of the two covariants

$$(ab)^2 a_x^{n-2} b_x^{n-2} \text{ and } c_x^n$$

The identities are, in particular, of service in reducing symbolic products to standard forms. A symbolical expression may be always so transformed that the power of any determinant factor (ab) is even. For we may in any product interchange a and b without altering its signification; therefore

$$(ab)^{2m+1} \phi_1 = -(ab)^{2m+1} \phi_2,$$

where ϕ_1 becomes ϕ_2 by the interchange, and hence

$$(ab)^{2m+1} \phi_1 = \frac{1}{2}(ab)^{2m+1}(\phi_1 - \phi_2);$$

and identity (I.) will always result in transforming $\phi_1 - \phi_2$ so as to make it divisible by (ab) .

Ex. gr.

$$(ab)(ac)b_x c_x = -(ab)(bc)a_x c_x = \frac{1}{2}(ab)c_x \{ (ac)b_x - (bc)a_x \} = \frac{1}{2}(ab)^2 c_x^2;$$

so that the covariant of the quadratic on the left is half the product of the quadratic itself and its only invariant. To obtain the corresponding theorem concerning the general form of even order we multiply throughout by $(ab)^{2m-2} c_x^{2m-2}$ and obtain

$$(ab)^{2m-1} (ac)b_x c_x^{2m-1} = \frac{1}{2}(ab)^{2m} c_x^{2m}.$$

Paying attention merely to the determinant factors there is no form with one factor since (ab) vanishes identically. For two factors the standard form is $(ab)^2$; for three factors $(ab)^2(ac)$; for four factors $(ab)^4$ and $(ab)^2(cd)^2$; for five factors $(ab)^4(ac)$ and $(ab)^2(ac)(de)^2$; for six factors $(ab)^6$, $(ab)^2(bc)(ca)^2$, and $(ab)^2(cd)^2(ef)^2$. It will be a useful exercise for the reader to interpret the corresponding covariants of the general quantic, to show that some of them are simple powers or products of other covariants of lower degrees and order.

The Polar Process.—We are now going to introduce other sets of cogredient variables into the symbolic products. The μ^{th} polar of the binary form $a_x^n = f$ with regard to y is expressed by

$$(a_x^n)_y^\mu = f_y^\mu = (a_1 x_1 + a_2 x_2)^{n-\mu} (a_1 y_1 + a_2 y_2)^\mu = a_x^{n-\mu} a_y^\mu;$$

i. e., μ of the symbolic factors of the form are replaced by μ others in which y_1, y_2 , replace x_1, x_2 .

By giving μ the values 0, 1, 2, ... n we obtain in all $n+1$ y -polars in regard to x . They may be obtained by partial differential operations upon the form. Write in symbolic form

$$\frac{\partial^\mu f}{\partial a_1^\mu \partial a_2^{n-\mu}} = \frac{n!}{(n-\mu)!} f_1^\mu f_2^{n-\mu},$$

so that

$$\frac{\partial f}{\partial a_1} = n f_1, \quad \frac{\partial f}{\partial a_2} = n f_2;$$

and let

$$f_y = f_1 y_1 + f_2 y_2;$$

then

$$n f_1 = n a_x^{n-1} a_1, \quad n f_2 = n a_x^{n-1} a_2; \\ f_y = a_x^{n-1} a_y,$$

the first polar.

Similarly

$$f_1^2 = a_x^{n-2} a_1^2, \quad f_1 f_2 = a_x^{n-2} a_1 a_2, \quad f_2^2 = a_x^{n-2} a_2^2, \\ f_y^2 = (f_1 y_1 + f_2 y_2)^2 = a_x^{n-2} a_y^2,$$

the second polar; and in general the μ^{th} polar is

$$f_y^\mu = (f_1 y_1 + f_2 y_2)^\mu = a_x^{n-\mu} a_y^\mu \\ = \sum \binom{\mu}{\alpha} f_1^\alpha f_2^{\mu-\alpha} \\ = \frac{(n-\mu)!}{n!} \sum \binom{\mu}{\alpha} y_1^\alpha y_2^{\mu-\alpha} \frac{\partial^\mu f}{\partial a_1^\alpha \partial a_2^{\mu-\alpha}}.$$

In symbolic form we may write

$$f_y^\mu = \frac{(n-\mu)!}{n!} \left(y_1 \frac{\partial}{\partial a_1} + y_2 \frac{\partial}{\partial a_2} \right)^\mu f = \frac{(n-\mu)!}{n!} y^\mu f.$$

All the polars may be generated from a_x^n by writing therein $x_1 + \lambda y_1, x_2 + \lambda y_2$ for x_1, x_2 respectively, for a_x^n becomes $(a_x + \lambda a_y)^n$ and

$$(a_x + \lambda a_y)^n = a_x^n + \binom{n}{1} \lambda a_x^{n-1} a_y + \binom{n}{2} \lambda^2 a_x^{n-2} a_y^2 + \dots + \lambda^n a_y^n \\ = f_y^n + \binom{n}{1} \lambda f_y^{n-1} + \binom{n}{2} \lambda^2 f_y^{n-2} + \dots + \lambda^n f_y^n.$$

Ex. gr. The first polar of $a_x^2 = a_x a_y$

$$= (a_1 x_1 + a_2 x_2)(a_1 y_1 + a_2 y_2) = a_1^2 x_1 y_1 + a_1 a_2 (x_1 y_2 + x_2 y_1) + a_2^2 x_2 y_2 \\ = \bar{a}_0 x_1 y_1 + \bar{a}_1 (x_1 y_2 + x_2 y_1) + \bar{a}_2 x_2 y_2 \\ = (\bar{a}_0 x_1 + \bar{a}_1 x_2) y_1 + (\bar{a}_1 x_1 + \bar{a}_2 x_2) y_2 \\ = \frac{1}{2} \left(y_1 \frac{d}{dx_1} + y_2 \frac{d}{dx_2} \right) (\bar{a}_0 x_1^2 + 2\bar{a}_1 x_1 x_2 + \bar{a}_2 x_2^2).$$

Similarly the second polar of the binary cubic is

$$(\bar{a}_0 x_1 + \bar{a}_1 x_2) y_1^2 + 2(\bar{a}_1 x_1 + \bar{a}_2 x_2) y_1 y_2 + (\bar{a}_2 x_1 + \bar{a}_3 x_2) y_2^2$$

which is $a_x a_y^2$ or

$$\frac{1}{6} \left(y_1 \frac{d}{dx_1} + y_2 \frac{d}{dx_2} \right)^2 a_x^3.$$

The operation of taking the polar results in a symbolic product and the repetition of the process, in regard to new cogredient sets of variables, must result in symbolic forms. It is therefore an invariant process, and all the forms obtained are invariants in regard to linear transformations, in accordance with the same scheme of substitutions, of the several sets of variables.

An important associated operation is

$$\frac{\partial^2}{\partial x_1 \partial y_2} - \frac{\partial^2}{\partial x_2 \partial y_1},$$

which performed upon any polar causes it to vanish; for

$$\frac{\partial^2}{\partial x_1 \partial y_2} a_x^{n-\mu} a_y^\mu = (n-\mu) \mu a_1 a_2 a_x^{n-\mu-1} a_y^{\mu-1};$$

and conversely it can be shown that every function which it causes to vanish is a polar.

It is usual to write

$$\frac{1}{m \cdot n} \left(\frac{\partial^2}{\partial x_1 \partial y_2} - \frac{\partial^2}{\partial x_2 \partial y_1} \right) a_x^m b_y^n = \Omega a_x^m b_y^n,$$

and we have the theorem that Ω , performed upon any invariant form, produces an invariant form.

Ex. gr.

$$\Omega a_x^m b_y^n = \frac{1}{m \cdot n} (m n a_1 b_2 - m n a_2 b_1) a_x^{m-1} b_y^{n-1} \\ = (ab) a_x^{m-1} b_y^{n-1}; \\ \Omega^2 a_x^m b_y^n = (ab)^2 a_x^{m-2} b_y^{n-2};$$

and in general

$$\Omega^\mu a_x^m b_y^n = (ab)^\mu a_x^{m-\mu} b_y^{n-\mu}.$$

These are invariants of forms which are binary in two sets of variables and, by putting $y=x$, we obtain simultaneous invariants of two binary forms in a single set of variables. Observe the easy passage from a bipartite form to two unipartite forms. The polar of a product $a_x^m \cdot b_x^n$ is obtained by, first of all, writing $a_x^m \cdot b_x^n$ in the symbolic form p_x^{m+n} ; thus if

$$F = a_x^m \cdot b_x^n = p_x^{m+n}, \\ F_y = p_x^{m+n-k} p_y^k;$$

now, in $p_x^{m+n} = a_x^m \cdot b_x^n$, write $x + \lambda y$ for x , so that

$$(p_x + \lambda p_y)^{m+n} = (a_x + \lambda a_y)^m \cdot (b_x + \lambda b_y)^n;$$

expanding and comparing coefficients of λ^k

$$\binom{m+n}{k} P_x^{m+n-k} P_y^k = \sum_s \binom{m}{s} \binom{n}{k-s} a_x^{m-s} a_y^s b_x^{n-k+s} b_y^{k-s};$$

or writing $a_x^m = f, b_x^n = \phi,$

$$\binom{m+n}{k} (f \cdot \phi)_y^k = \sum_s \binom{m}{s} \binom{n}{k-s} f_y^s \phi_y^{k-s},$$

a general formula for the polar of a product of two forms. The expression $f_y^s \phi_y^{k-s}$ is called a *member of the polar*; writing it G_s we have altogether a series of $k+1$ members, viz.—

$$G_0, G_1, G_2, \dots, G_k;$$

and

$$\binom{m+n}{k} (f \cdot \phi)_y^k = \sum_s \binom{m}{s} \binom{n}{k-s} G_s.$$

Two members, G_s, G_{s+1} , are said to be adjacent, and we can prove that the difference between any two adjacent members contains the factor $(ab)(xy)$; for

$$G_s - G_{s+1} = f_y^s \phi_y^{k-s} - f_y^{s+1} \phi_y^{k-s-1} = a_x^{m-s-1} a_y^{s+1} b_x^{n-k+s-1} b_y^{k-s-1} (ab)(xy);$$

whence also

$$a_x b_x (G_s - G_{s+1}) = f_y^s \phi_y^{k-s-1} (ab)(xy),$$

wherein $f_y^s \phi_y^{k-s-1}$ is a member of the $k-1^{\text{th}}$ polar of $F=f \cdot \phi$. Again, if s be less than t ,

$$G_s - G_t = G_s - G_{s+1} + G_{s+1} - G_{s+2} + \dots + G_{t-1} - G_t;$$

and since the successive differences

$$G_s - G_{s+1}, G_{s+1} - G_{s+2}, \dots, G_{t-1} - G_t,$$

involve, each of them, the factor $(ab)(xy)$; so also does $G_s - G_t$ the difference between any two members of the polar. Also the cofactor of $(ab)(xy)$ in $a_x b_x (G_s - G_t)$ must be a sum of members of the $k-1^{\text{th}}$ polar of F .

Moreover, since

$$\binom{m+n}{k} F_y^k = \sum_s \binom{m}{s} \binom{n}{k-s} G_s,$$

and

$$\sum_s \binom{m}{s} \binom{n}{k-s} = \binom{m+n}{k},$$

we may write

$$F_y^k = c_0 G_0 + c_1 G_1 + \dots + c_k G_k,$$

where $c_0 + c_1 + \dots + c_k = 1$, and

$$G_s = (c_0 + c_1 + \dots + c_k) G_s;$$

we obtain, by subtraction,

$$F_y^k - G_s = c_0 (G_0 - G_s) + c_1 (G_1 - G_s) + \dots + c_k (G_k - G_s),$$

which proves that the difference between the complete polar and any one of its members contains the factor $(ab)(xy)$, and that the cofactor of $a_x b_x (F_y^k - G_s)$ is a linear function of the members of the $k-1^{\text{th}}$ polar of F . Since

$$a_x b_x (G_s - G_t) = (f_y^s \phi_y^{k-s-1} + f_y^{s+1} \phi_y^{k-s-2} + \dots + f_y^{t-1} \phi_y^{k-t}) (ab)(xy),$$

we find

$$\begin{aligned} & a_x b_x (F_y^k - G_s) \div (ab)(xy) \\ &= c_0 f_y^0 \phi_y^{k-1} + (c_0 + c_1) f_y^1 \phi_y^{k-2} + \dots + (c_0 + c_1 + \dots + c_{s-1}) f_y^{s-1} \phi_y^{k-s} \\ & - (c_s + c_{s+1} + \dots + c_k) f_y^s \phi_y^{k-s-1} - \dots - c_k f_y^k \phi_y^0; \end{aligned}$$

and we see that the cofactor of (xy) in $F_y^k - G_s$ is a sum of terms obtained by writing (ab) for $a_x b_x$ in the cofactor of $(ab)(xy)$, in the expression of $a_x b_x (F_y^k - G_s)$. Hence the cofactor of (xy) in $F_y^k - G_s$ is a linear function of the members of the $k-1^{\text{th}}$ polar of $(ab)a_x^{m-1} b_x^{n-1}$, which is a covariant of $F=f \cdot \phi$, usually written $(f, \phi)^1$ and termed (see *post*) the first transvectant of f over ϕ . The $k-1^{\text{th}}$ polar will be written

$$\{(f, \phi)^1\}_y^{k-1},$$

and

$$G\{(f, \phi)^1\}_y^{k-1}$$

will denote one of its members. We thus have the relation

$$G_s = G_s \{(f, \phi)^1\}_y^k = \{(f, \phi)^1\}_y^k + (xy) \sum G\{(f, \phi)^1\}_y^{k-1};$$

or, in words, we express a member of the k^{th} polar of $f \cdot \phi$ as a sum of the polar itself, and the product of (xy) into a linear function of the members of the $k-1^{\text{th}}$ polar of the first transvectant of f over ϕ . We may similarly treat any member

$$G\{(f, \phi)^1\}_y^{k-1}$$

of the $k-1^{\text{th}}$ polar of the first transvectant, so as to exhibit it as a sum of the polar itself and a product of (xy) into a linear function of the members of the $k-2^{\text{th}}$ polar of the second transvectant,

$$(ab)^2 a_x^{m-2} b_x^{n-2} = (f, \phi)^2,$$

of f over ϕ ; we can continue the process so as finally to reach the development

$$G_s = \{(f, \phi)^k\}_y^k + (xy) c_1 \{(f, \phi)^1\}_y^{k-1} + (xy)^2 c_2 \{(f, \phi)^2\}_y^{k-2} + \dots + (xy)^k c_k (f, \phi)^k.$$

Hence the theorem which states that any member of the k^{th} polar of the product of two forms f, ϕ may be expanded in ascending powers of the determinant (xy) , the cofactor of $(xy)^k$ being a numerical multiple of the $k-s^{\text{th}}$ polar of the s^{th} transvectant of f over ϕ . All of these transvectants are, as we shall show presently, covariants.

Ex. gr. Let $F=f \cdot \phi = a_x^2 \cdot b_x^2$; and let us exhibit the second member of the second polar in the desired form,

$$\binom{2}{2} F_y^2 = \binom{2}{2} \binom{2}{2} F_y^2 \phi_y^0 + \binom{2}{2} \binom{2}{2} F_y^1 \phi_y^1 + \binom{2}{2} \binom{2}{2} f_y^2 \phi_y^0,$$

or

$$F_y^2 = \frac{1}{5} (a_x^2 b_x^2 b_y^2 + 3a_x^2 a_y b_x^2 b_y + a_x a_y^2 b_x^2);$$

the second member is $a_x^2 a_y b_x^2 b_y$ and

$$\begin{aligned} F_y^2 - a_x^2 a_y b_x^2 b_y &= \frac{1}{5} (a_x^2 b_x^2 b_y^2 - a_x^2 a_y b_x^2 b_y + a_x a_y^2 b_x^2 - a_x^2 a_y b_x^2 b_y) \\ &= \frac{1}{5} a_x b_x (a_x b_y - a_y b_x)^2 \\ &= \frac{1}{5} (xy)^2 (ab)^2 a_x b_x = \frac{1}{5} (xy)^2 (f, \phi)^2; \end{aligned}$$

therefore

$$a_x^2 a_y b_x^2 b_y = F_y^2 - \frac{1}{5} (xy)^2 (f, \phi)^2,$$

the result. In this instance the term, involving the first power of (xy) , happens to be absent. In regard to the polar of a product of n forms it is easy to establish that if

$$\begin{aligned} F_1 &= a_x^{m_1} f_1, f_2 = b_x^{m_2} \dots f_n = b_x^{m_n}, \\ & \binom{\sum m_i}{k} (f_1 f_2 \dots f_n)_y^k \\ &= \sum \binom{m_1}{i_1} \binom{m_2}{i_2} \dots \binom{m_n}{i_n} (f_1)_{i_1}^{i_1} (f_2)_{i_2}^{i_2} \dots (f_n)_{i_n}^{i_n}, \end{aligned}$$

where

$$\sum i_i = k.$$

As regards polars, with more than two sets of cogredient variables, the generating function is

$$(a_x + \lambda a_y + \mu a_z + \dots)^n;$$

and we can establish the theorem that every symbolio product involving several sets of cogredient variables can be expanded into a number of terms, each of which is a complete polar, multiplied by a product of powers of the determinant factors $(xy), (xz), (yz), \dots$.

Transvection.—Certain covariants, termed transvectants, have been met with above. We have seen that (ab) is a simultaneous invariant of the two different linear forms $f = a_x, \phi = b_x$, and we observe that (ab) is equivalent to the differential operation

$$\frac{\partial f}{\partial a_x} \frac{\partial \phi}{\partial a_x} - \frac{\partial f}{\partial a_x} \frac{\partial \phi}{\partial a_x}.$$

The process is generalized by forming the function

$$\frac{(m-k)! (n-k)!}{m! n!} \left(\frac{\partial f}{\partial a_1} \frac{\partial \phi}{\partial a_2} - \frac{\partial f}{\partial a_2} \frac{\partial \phi}{\partial a_1} \right)^k,$$

where f, ϕ are any two binary forms; it is called the k^{th} transvectant of f over ϕ . It should be noted that the multiplication of operations is symbolic in the sense that the operation in the bracket is to be performed k times successively. The transvectant is denoted by

$$(f, \phi)^k.$$

Thus if

$$f = a_x^m, \phi = b_x^n,$$

$$\binom{m}{a_x} \binom{n}{b_x}^1 = (ab) a_x^{m-1} b_x^{n-1},$$

$$\binom{m}{a_x} \binom{n}{b_x}^k = (ab)^k a_x^{m-k} b_x^{n-k},$$

from which it is evident that the k^{th} transvectant is a simultaneous covariant of the two forms.

If $m \geq n$ there are $n+1$ transvectants corresponding to the values $0, 1, 2, \dots, n$ of k ; if $k=0$ we have the product of the two forms, and for all values of $k > n$ the transvectants vanish. In general we may have any two forms

$$\phi^p = (\phi_1 x_1 + \phi_2 x_2)^p, \psi^q = (\psi_1 x_1 + \psi_2 x_2)^q,$$

$\phi_1, \phi_2; \psi_1, \psi_2$ being the umbræ, as usual, and for the k^{th} transvectant we have

$$(\phi_x^p, \psi_x^q)^k = (\phi\psi)^k \phi_x^{p-k} \psi_x^{q-k},$$

a simultaneous covariant of the two forms. We may suppose ϕ_x^p, ψ_x^q to be any two covariants appertaining to a system, and the process of transvection supplies a means of proceeding from them to other covariants.

The two forms a_x^m, b_x^n , or ϕ^p, ψ^q may be identical; we then have the k^{th} transvectant of a form over itself which may, or may not, vanish identically; and, in the latter case, is a covariant of the single form. It is obvious that, when k is uneven, the k^{th} transvectant of a form over itself does vanish. We have seen that transvection is equivalent to the performance of partial differential operations upon the two forms, but, practically, we may regard the process as merely substituting $(ab)^k, (\phi\psi)^k$ for $a_x^k b_x^k, \phi_x^k \psi_x^k$ respectively in the symbolic product subjected to transvection. It is essentially an operation performed upon the product of two forms. If, then, we require the transvectants of the two forms $f + \lambda f', \phi + \mu \phi'$, we take their product

$$f\phi + \lambda f'\phi + \mu f\phi' + \lambda\mu f'\phi',$$

and the k^{th} transvectant is simply obtained by operating upon each term separately, viz. —

$$(f, \phi)^k + \lambda(f', \phi)^k + \mu(f, \phi')^k + \lambda\mu(f', \phi')^k;$$

and, moreover, if we require to find the k^{th} transvectant of one linear system of forms over another we have merely to multiply the two systems, and take the k^{th} transvectant of the separate products.

The process of transvection is connected with the operations Ω ; for

$$\Omega^k(a_x^m b_y^n) = (ab)^k a_x^{m-k} b_y^{n-k};$$

or
$$\Omega^k(a_x^m b_y^n)_{y=x} = (f, \phi)^k;$$

so also is the polar process, for since

$$f_y^k = a_x^{m-k} b_y^k, \phi_y^k = b_x^{n-k} b_y^k$$

if we take the k^{th} transvectant of f_y^k over ϕ_y^k , regarding y_1, y_2 as the variables,

$$(f_y^k, \phi_y^k)^k = (ab)^k a_x^{m-k} b_x^{n-k} = (f, \phi)^k;$$

or the k^{th} transvectant of the k^{th} polars, in regard to y , is equal to the k^{th} transvectant of the forms. Moreover, the k^{th} transvectant $(ab)^k a_x^{m-k} b_x^{n-k}$ is derivable from the k^{th} polar of a_x^m , viz., $a_x^{m-k} a_y^k$ by substituting for y_1, y_2 the cogredient quantities $b_2, -b_1$, and multiplying by b_x^{n-k} .

Frequently the forms to which the process is applied are, each of them, products of other forms.

Thus suppose

$$f = a_x^{m_1} b_x^{m_2}, \phi = a_x^{n_1} \beta_x^{n_2},$$

we find

$$\begin{aligned} & (m_1 + m_2)(n_1 + n_2) (a_x^{m_1} b_x^{m_2}, a_x^{n_1} \beta_x^{n_2})^1 \\ &= m_1 n_1 (aa)^{m_1-1} b_x^{m_2} a_x^{n_1-1} \beta_x^{n_2} + m_1 n_2 (a\beta) a_x^{m_1-1} b_x^{m_2} a_x^{n_1} \beta_x^{n_2-1} \\ &+ m_2 n_1 (ba) a_x^{m_1} a_x^{n_1-1} b_x^{m_2-1} \beta_x^{n_2} + m_2 n_2 (b\beta) a_x^{m_1} b_x^{m_2-1} a_x^{n_1} \beta_x^{n_2-1}; \end{aligned}$$

where, on the dexter, there is a term for every pair of umbræ, one taken from f and one from ϕ . The sum of the numerical coefficients of the members of the transvectant is unity. If we suppose the product $a_x^{m_1} b_x^{m_2} a_x^{n_1} \beta_x^{n_2}$ written out as a product of $m_1 + m_2 + n_1 + n_2$ factors; the coefficient $(m_1 + m_2)(n_1 + n_2)$ enumerates the number of ways of picking out one factor from $a_x^{m_1} b_x^{m_2}$ and one factor from $a_x^{n_1} \beta_x^{n_2}$; the coefficient $m_1 n_2$ on the dexter of the above results shows the number of ways of picking out one factor from $a_x^{m_1}$ and one from $\beta_x^{n_2}$; consequently the fraction

$\frac{m_1 n_2}{(m_1 + m_2)(n_1 + n_2)}$, which affects one term of the transvectant, denotes the probability of picking out the pair $a_x \beta_x$ when a random selection is made of one factor from $a_x^{m_1} b_x^{m_2}$ and one factor from $a_x^{n_1} \beta_x^{n_2}$. Similarly if

$$f = a_x^{m_1} b_x^{m_2} c_x^{m_3} \dots c_x^{m_s}, \phi = a_x^{n_1} \beta_x^{n_2} \gamma_x^{n_3} \dots \sigma_x^{n_r},$$

$$\sum m = m, \sum n = n,$$

the first transvectant will consist of sr terms, and any term, involving say the determinant factor $(a\beta)$, will have a numerical coefficient which denotes the probability of a random selection of two factors, one each from f and ϕ , being $a_x \beta_x$. The sum of the coefficients is unity. Proceeding to the second transvectant each term is treated in a similar manner, with the result that a number of terms are obtained; one such term is, say

$$\frac{m_1 n_2 \cdot m_1 - 1 \cdot n_3}{m(m-1)n(n-1)} (a\beta)(a\gamma) a_x^{m_1-2} b_x^{m_2} \dots a_x^{n_1} \beta_x^{n_2-1} \gamma_x^{n_3-1} \dots,$$

and the numerical coefficients denote the probability of two random selections of pairs of symbols yielding $(a\beta)(a\gamma)$, and so on. Hence, in general, the k^{th} transvectant involves terms, each of which has k determinant factors, and a numerical coefficient which denotes the probability of such factors arising from a random selection. Hence the sum of the coefficients of the terms must be unity.

Ex. gr.
$$(a_x b_x, c_x d_x)^1 = \frac{1}{4} (ac) b_x d_x + \frac{1}{4} (ad) b_x c_x$$

$$+ \frac{1}{4} (bc) a_x d_x + \frac{1}{4} (bd) a_x c_x;$$

$$(a_x b_x, c_x d_x)^2 = \frac{1}{2} \{ (ac)(bd) + (ad)(bc) \}.$$

Ex. gr. We will find the fourth transvectant, of a binary quartic upon itself, so as to obtain the invariant $(ab)^4$ in terms of the roots of the quartic.

$$\text{Let } a_x^4 = b_x^4 = (x_1 - a_1 x_2)(x_1 - a_2 x_2)(x_1 - a_3 x_2)(x_1 - a_4 x_2),$$

and observe that $(x_1 - a_r x_2, x_1 - a_s x_2)^1 = a_r - a_s$; therefore $(a_x^4, b_x^4)^1$ is a sum of a number of terms, each of which involves a factor of the form $a_r - a_s$, and proceeding we find $(a_x^4, b_x^4)^4$ equal to

$$\frac{1}{4!} \sum (a_i - a_1)(a_j - a_2)(a_k - a_3)(a_l - a_4),$$

the summation being for every permutation $ijkl$ of the numbers $1, 2, 3, 4$. There are $4!$ terms, but certain of them vanish. Those which survive correspond to the permutations in which each number is displaced. These are nine in number, and we can, finally, throw the result into the form

$$\frac{1}{4!} \{ (a_1 - a_2)(a_3 - a_4) + (a_1 - a_3)(a_2 - a_4) + (a_1 - a_4)(a_2 - a_3) \}^2;$$

a well-known expression of the simplest invariant of the binary quartic. It will be seen later that the coefficient \bar{a}_0 of every covariant of a binary form is a symmetric function of the differences of the roots of the forms.

The various transvectants can be obtained by partial differential operations in which the independent variables are $a_x, b_x, \dots, \alpha_x, \beta_x, \dots$. Dropping, temporarily, the suffix x , we can see that

$$(a_x^{m_1} b_x^{m_2}, a_x^{n_1} \beta_x^{n_2})^1 \equiv (a^{m_1} b^{m_2}, a^{n_1} \beta^{n_2})^1$$

can be obtained by operating upon the product with

$$(aa) \frac{a^2}{a da} + (a\beta) \frac{a^2}{a da \beta} + (ba) \frac{a^2}{a b da} + (b\beta) \frac{a^2}{a b da \beta},$$

and multiplying by $\frac{1}{(m_1 + m_2)(n_1 + n_2)}$. Disregarding the multi-

plier we obtain the k^{th} transvectant by k successive operations of this operator, the quantities operated upon being $a = a_x, b = b_x, \dots$ and not the determinant factors. In general the operator is

$$\sum (aa) \frac{a^2}{a da},$$

the number of terms in the operator being sr , and k successive operations produce, to a factor *près*, the k^{th} transvectant.

Ex. gr. To find in this manner the second transvectant of $(ab)^2 a^{n-2} b^{n-2}$ upon itself, we take the product $(ab)^2 (cd)^2 a^{n-2} b^{n-2} c^{n-2} d^{n-2}$ and perform the operation

$$\left\{ (ac) \frac{a^2}{a da c} + (ad) \frac{a^2}{a da d} + (bc) \frac{a^2}{a b da} + (bd) \frac{a^2}{a b da d} \right\}^2,$$

when we obtain the result in the form of a linear function of the three forms:—

$$\begin{aligned} & (ab)^2 (ac)^2 (cd)^2 a^{n-4} b^{n-2} c^{n-4} d^{n-2} \\ & (ab)^2 (cd)^2 (ac)(ad) a^{n-4} b^{n-2} c^{n-3} d^{n-3} \\ & (ab)^2 (cd)^2 (ac)(bd) a^{n-3} b^{n-3} c^{n-3} d^{n-3}. \end{aligned}$$

A very important particular case of transvection is that in which $f = M a_x^{m_1} b_x^{m_2} \dots, \phi = g_x^n$; ϕ is the original form, f a covariant of ϕ , and M is the product of determinant factors involved in f . Writing for convenience

$$f = M a_x^{m_1} b_x^{m_2} \dots, \phi = g_x^n,$$

the operator, for the k^{th} transvectant, becomes effectively

$$\frac{1}{g^k} \left\{ (ag) \frac{d}{da} + (bg) \frac{d}{db} + (cg) \frac{d}{dc} + \dots \right\}^k;$$

or if we take the operand to be f and not $f \cdot g^n$ we may consider the operation

$$\left\{ (ag) \frac{d}{da} + (bg) \frac{d}{db} + (cg) \frac{d}{dc} + \dots \right\}^k,$$

and disregard the factor g^{-k} .

We can transform the operator by expressing, by means of one of the fundamental identities, (bg) , (cg) , ... in terms of (ag) and determinant factors which are free from g . Thus

$$\begin{aligned} & (ag) \frac{d}{da} + (bg) \frac{d}{db} + (cg) \frac{d}{dc} + \dots \\ &= \frac{1}{a} (ag) \left(a \frac{d}{da} + b \frac{d}{db} + c \frac{d}{dc} + \dots \right) \\ & \quad - \frac{g}{a} \left\{ (ab) \frac{d}{db} + (ac) \frac{d}{dc} + \dots \right\}. \end{aligned}$$

Now

$$\left(a \frac{d}{da} + b \frac{d}{db} + c \frac{d}{dc} + \dots \right) f = mf,$$

where $m = m_1 + m_2 + m_3 + \dots$; therefore the first transvectant is

$$\frac{1}{g} \frac{1}{a} (ag) m f g^n - \frac{1}{a} M a m_1 g^n \left\{ (ab) \frac{d}{db} + (ac) \frac{d}{dc} + \dots \right\} b^{m_2} c^{m_3} \dots,$$

an important form, because it shows that the transvectant can be broken up into two portions, in only one of which does the symbol g occur in the determinant factors. Conversely, if we have a form involving $m+1$ symbols in the determinant factors, in one of which g occurs only once, we may exhibit it by means of the transvectant of a form not involving g upon the original form, and of a form whose determinant factors involve only m symbols and do not involve g . This theorem is of great significance in the proof of Gordan's theorem concerning the finite number of covariants of a given form, and we must further generalize it. The operator for the second transvectant is

$$\left\{ (ag) \frac{d}{da} + (bg) \frac{d}{db} + (cg) \frac{d}{dc} + \dots \right\}^2,$$

which may be written either as

$$\frac{1}{a^2} \left[(ag) \left(a \frac{d}{da} + b \frac{d}{db} + \dots \right) - g \left\{ (ab) \frac{d}{db} + (ac) \frac{d}{dc} + \dots \right\} \right]^2,$$

or as

$$\begin{aligned} & \frac{1}{ab} \left[(ag) \left(a \frac{d}{da} + b \frac{d}{db} + \dots \right) - g \left\{ (ab) \frac{d}{db} + (ac) \frac{d}{dc} + \dots \right\} \right] \\ & \times \left[(bg) \left(a \frac{d}{da} + b \frac{d}{db} + \dots \right) - g \left\{ (ba) \frac{d}{da} + (bc) \frac{d}{dc} + \dots \right\} \right]. \end{aligned}$$

Taking the first form we find the second transvectant to be

$$m(m-1) \frac{1}{a^2} (ag)^2 f \cdot g^{m-2}$$

together with a number of terms in which (ag) occurs at most once. Hence a form, containing $m+1$ symbols and the $m+1^{\text{th}}$ symbol g only in the form $(ag)^2$, can be exhibited by means of the second transvectant of a form in m symbols over the original form and of a form which involves (ag) at most once; and now, combining the former result, we find that a form in $m+1$ symbols which involves the $m+1^{\text{th}}$ symbol g only in the form $(ag)^2$, can be expressed by means of forms involving m symbols, and by first and second transvectants of such a form upon the original form. The second form of operator above written leads to the same conclusion in regard to the factor $(ag)(bg)$. Similarly it is proved that a form in $m+1$ symbols which involves the determinant factors (ag) , (bg) , ... to the order k is expressible by means of forms in m symbols and 1st, 2nd, ... k^{th} transvectants of such forms upon the original forms.

Every symbolic product is expressible as a sum of transvectants.

Ex. gr. Gordan takes as an example

$$\phi_x^3 = (ab)^2 (ac)^2 (bc)^2 a_x b_x c_x;$$

substituting for c_1, c_2 the cogredient variables $-y_2, y_1$ we obtain $(xy)(ab)^2 a_x b_x a_y^2 b_y^2$ which is a member of the fourth polar of $(ab)^2 a_x^2 b_x^2$ multiplied by (xy) ; putting $(ab)^2 a_x^2 b_x^2 = G_x^2 = (ab)^2 F_x^2$ we find

$$a_x b_x a_y^2 b_y^2 = (F_x^2)^4 + \frac{2}{5} (xy) \left\{ (ab) a_x^2 b_x^2 \right\}_y^3;$$

$$\therefore (ab)^2 a_x b_x a_y^2 b_y^2 = (G_x^2)^4 + \frac{2}{5} (xy) (H_x^2)^3,$$

where

$$H_x^2 = (ab)^3 a_x^2 b_x^2.$$

Now for y_1, y_2 write $c_2, -c_1$ and multiply by c_x .

$$\begin{aligned} \phi_x^3 &= c_x G_x^2 (Gc)^4 + \frac{2}{5} c_x^2 H_x (Hc)^3 \\ &= (G_x^2, c_x^5)^4 + \frac{2}{5} (H_x^2, c_x^5)^3, \\ &= \left\{ (ab)^2 a_x^2 b_x^2, c_x^5 \right\}^4 + \frac{2}{5} \left\{ (ab)^3 a_x^2 b_x^2, c_x^5 \right\}^3; \end{aligned}$$

or if $a_x^5 = b_x^5 = c_x^5 = f = f' = f''$, this is

$$\phi_x^3 = \left\{ (f, f')^2, f'' \right\}^4 + \frac{2}{5} \left\{ (f, f')^3, f'' \right\}^3.$$

In general it suffices to say that we transform one set of umbral symbols to a new set of variables, and make use as above of the properties of polars. The theorem establishes that transvectants are as inclusive as symbolic products in general.

First and Second Transvectants.—A few words must be said about the first two transvectants as they are of exceptional interest. Since, if $f = a_x^m, \phi = b_x^n$,

$$(f, \phi)^1 = \frac{1}{mn} \left(\frac{\partial f}{\partial a_1} \frac{\partial \phi}{\partial a_2} - \frac{\partial f}{\partial a_2} \frac{\partial \phi}{\partial a_1} \right) = (ab) a_x^{m-1} b_x^{n-1} = J,$$

the first transvectant differs but by a numerical factor from the Jacobian or functional determinant of the two forms. We can find an expression for the first transvectant of $(f, \phi)^2$ over another form ψ .

For

$$(m+n)(f, \phi)_y^1 = n f \cdot \phi_y^1 + m f_y^1 \cdot \phi,$$

and

$$\begin{aligned} f, \phi_y^1 - f_y \cdot \phi &= (a_x b_y - a_y b_x) a_x^{m-1} b_x^{n-1} = (xy)(f, \phi)^1; \\ \therefore (f, \phi)_y^1 &= f_y^1 \cdot \phi + \frac{n}{m+n} (xy)(f, \phi)^1. \end{aligned}$$

Put $m-1$ for $m, n-1$ for n , and multiply through by (ab) ; then

$$\begin{aligned} \{ (f, \phi) \}_y^1 &= (ab) a_x^{m-2} a_y b_x^{n-1} + \frac{n-1}{m+n-2} (xy)(f, \phi)^2, \\ &= (ab) a_x^{m-1} b_x^{n-2} b_y - \frac{m-1}{m+n-2} (xy)(f, \phi)^2. \end{aligned}$$

Multiply by c_x^{p-1} and for y_1, y_2 write $c_2, -c_1$; then the right-hand side becomes

$$(ab)(bc) a_x^{m-1} b_x^{n-2} c_x^{p-1} + \frac{m-1}{m+n-2} c_x^p (f, \phi)^2,$$

of which the first term, writing $c_x^p = \psi$, is

$$\begin{aligned} & a_x^{m-2} b_x^{n-2} c_x^{p-2} (ab)(bc) a_x c_x \\ &= -\frac{1}{2} a_x^{m-2} b_x^{n-2} c_x^{p-2} \left\{ (bc)^2 a_x^2 + (ab)^2 c_x^2 - (ac)^2 b_x^2 \right\} \\ &= -\frac{1}{2} \left\{ a_x^m (bc)^2 b_x^{n-2} c_x^{p-2} + c_x^p (ab)^2 a_x^{m-2} b_x^{n-2} - b_x^n (ac)^2 a_x^{m-2} c_x^{p-2} \right\} \\ &= -\frac{1}{2} \left\{ (\phi, \psi)^2 \cdot f + (f, \phi)^2 \cdot \psi - (f, \psi)^2 \cdot \phi \right\}; \end{aligned}$$

and, if $(f, \phi)^1 = k_x^{m+n-2}$,

$$\left\{ (f, \phi)^1 \right\}_y^1 \cdot c_x^{p-1} = k_x^{m+n-3} k_y c_x^{p-1};$$

and this, on writing $c_2, -c_1$ for y_1, y_2 , becomes

$$(kc) k_x^{m+n-3} c_x^{p-1} = \left\{ (f, \phi)^1, \psi \right\}^1;$$

$$\therefore \left\{ (f, \phi), \psi \right\}^1 = \frac{1}{2} \left\{ \frac{m-n}{m+n-2} (f, \phi)^2 \cdot \psi + (f, \psi)^2 \cdot \phi - (\phi, \psi)^2 \cdot f \right\};$$

and thence it appears that the first transvectant of $(f, \phi)^1$ over ψ is always expressible by means of forms of lower degree in the coefficients wherever each of the forms f, ϕ, ψ is of higher degree than the first in x_1, x_2 .

The second transvectant of a form over itself is called the Hessian of the form. It is

$$(f, f)^2 = (ab)^2 a_x^{m-2} b_x^{m-2} = H_x^{2m-4} = H;$$

unsymbolically it is a numerical multiple of the determinant $\frac{\partial^2 f}{\partial x_1^2} \frac{\partial^2 f}{\partial x_2^2} - \left(\frac{\partial^2 f}{\partial x_1 \partial x_2} \right)^2$. It is also the first transvectant of the differential coefficients of the form with regard to the variables, viz., $\left(\frac{\partial f}{\partial x_1}, \frac{\partial f}{\partial x_2} \right)^1$. For the quadratic it is the discriminant $(ab)^2$ and for the cubic the quadratic covariant $(ab)^2 a_x b_x$.

In general for a form in n variables the Hessian is

$$\begin{vmatrix} \frac{\partial^2 f}{\partial x_1^2} & \frac{\partial^2 f}{\partial x_1 \partial x_2} & \dots & \frac{\partial^2 f}{\partial x_1 \partial x_n} \\ \frac{\partial^2 f}{\partial x_1 \partial x_2} & \frac{\partial^2 f}{\partial x_2^2} & \dots & \frac{\partial^2 f}{\partial x_2 \partial x_n} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial^2 f}{\partial x_1 \partial x_n} & \frac{\partial^2 f}{\partial x_2 \partial x_n} & \dots & \frac{\partial^2 f}{\partial x_n^2} \end{vmatrix} = H_x^{n(n-2)} = H;$$

and there is a remarkable theorem which states that if $H=0$ and $n=2, 3, \text{ or } 4$ the original form can be exhibited as a form in 1, 2, 3 variables respectively.

Ex. gr. If $(ab)^2 a_x^{m-2} b_x^{m-2} = 0$, for the binary form a_x^m , the theorem states that the form is a simple m^{th} power $(a_1 x_1 + a_2 x_2)^m$, and therefore, by linear transformation, depends only on a single variable.

It may be verified that, if $a_x^m = f$,

$$\frac{1}{2}(xy)^2 H = f \cdot f_y^2 - (f_y^1)^2;$$

and now assuming f to have the form $a_x^\rho \phi_x^\sigma$ where a_x is a linear form and ϕ_x^σ a form of order σ ; $\rho + \sigma = m$,

$$\begin{aligned} f_y^1 &= \frac{\rho}{m} a_x^{\rho-1} a_y \phi_x^\sigma + \frac{\sigma}{m} a_x^\rho \phi_x^{\sigma-1} \phi_y, \\ m(m-1) f_y^2 &= \rho(\rho-1) a_x^{\rho-2} a_y^2 \phi_x^\sigma + 2\rho\sigma a_x^{\rho-1} a_y \phi_x^{\sigma-1} \phi_y \\ &\quad + \sigma(\sigma-1) a_x^\rho \phi_x^{\sigma-2} \phi_y^2, \end{aligned}$$

leading to

$$\begin{aligned} 0 &= m^2(m-1) \{ f \cdot f_y^2 - (f_y^1)^2 \} \\ &= \{ m\rho(\rho-1) - (m-1)\rho^2 \} a_x^{2\rho-2} a_y^2 \phi_x^2 \\ &\quad + 2\rho\sigma a_x^{2\rho-1} a_y \phi_x \phi_y + \{ m\sigma(\sigma-1) \phi_y^2 - (m-1)\sigma^2 \phi_y^1 \} a_x^{2\rho}; \end{aligned}$$

and, since each term on the right must vanish separately, $m = \rho$, $\sigma = 0$, which proves the theorem.

It has been established above that every symbolic product can be expressed by means of transvectants. We have now to show that every invariant can be expressed by means of symbolic products. It suffices to prove this for invariants as will appear.

When an invariant is expressed in terms of the umbrae $a_1, a_2; b_1, b_2; c_1, c_2; \dots$ it is homogeneous and of weight w in the series of symbols a_1, b_1, c_1, \dots and also in the series a_2, b_2, c_2, \dots . Let then an invariant j of weight w be written symbolically

$$j = (s_1 a_1 + s_2 b_1 + s_3 c_1 + \dots)^w (t_1 a_2 + t_2 b_2 + t_3 c_2 + \dots)^w;$$

transforming, by linear substitution, $J = (\lambda \mu)^w j$; or

$$\begin{aligned} J &= (s_1 a_\lambda + s_2 b_\lambda + s_3 c_\lambda + \dots)^w (t_1 a_\mu + t_2 b_\mu + t_3 c_\mu + \dots)^w \\ &= \{ (s_1 a_1 + s_2 b_1 + s_3 c_1 + \dots) \lambda_1 + (s_1 a_2 + s_2 b_2 + s_3 c_2 + \dots) \lambda_2 \}^w \\ &\quad \times \{ (t_1 a_1 + t_2 b_1 + t_3 c_1 + \dots) \mu_1 + (t_1 a_2 + t_2 b_2 + t_3 c_2 + \dots) \mu_2 \}^w \\ &= (p_1 \lambda_1 + p_2 \lambda_2)^w (q_1 \mu_1 + q_2 \mu_2)^w = p_\lambda q_\mu, \end{aligned}$$

where

$$\begin{aligned} p_1 &= s_1 a_1 + s_2 b_1 + s_3 c_1 + \dots, \\ p_2 &= s_1 a_2 + s_2 b_2 + s_3 c_2 + \dots, \\ q_1 &= t_1 a_1 + t_2 b_1 + t_3 c_1 + \dots, \\ q_2 &= t_1 a_2 + t_2 b_2 + t_3 c_2 + \dots, \end{aligned}$$

and

$$\begin{aligned} (pq) &= p_1 q_2 - p_2 q_1, \\ &= s_1 t_2 (ab) + s_1 t_3 (ac) + \dots + s_2 t_3 (bc) + \dots; \end{aligned}$$

now, since $p_\lambda q_\mu^w = (\lambda \mu)^w j$, if we operate with

$$\frac{\partial^2}{\partial \lambda_1 \partial \mu_2} - \frac{\partial^2}{\partial \lambda_2 \partial \mu_1}$$

we obtain

$$w^2 (pq) p_\lambda^{w-1} q_\mu^{w-1} = w(w+1) (\lambda \mu)^{w-1} j;$$

or

$$\frac{w}{w+1} (pq) p_\lambda^{w-1} q_\mu^{w-1} = (\lambda \mu)^{w-1} j;$$

again operating

$$\frac{w-1}{w+1} (pq) p_\lambda^{w-2} q_\mu^{w-2} = (\lambda \mu)^{w-2} j;$$

and continuing to operate we arrive at

$$\begin{aligned} j &= \frac{1}{w+1} (pq)^w, \\ &= \frac{1}{w+1} \{ s_1 t_2 (ab) + s_1 t_3 (ac) + \dots + s_2 t_3 (bc) + \dots \}^w; \end{aligned}$$

establishing that the invariant j is expressible as a sum of symbolic products, each product involving w determinant factors.

The Form $f + \lambda \phi$.—An important method for the formation of

covariants is connected with the form $f + \lambda \phi$, where f and ϕ are of the same order in the variables and λ is an arbitrary constant. If the invariants and covariants of this composite quantic be formed we obtain functions of λ such that the coefficients of the various powers of λ are simultaneous invariants of f and ϕ . In particular, when ϕ is a covariant of f , we obtain in this manner covariants of f . Consider, for example, the cubic

$$f = a_x^3,$$

and take for ϕ its cubic covariant

$$Q = (ab)^2 (cb) c_x^2 a_x.$$

If J be any covariant of f , denote by $J_{f+\lambda Q}$ the corresponding covariant of $f + \lambda Q$. There are four fundamental covariants of f , viz. :—

$$\begin{aligned} f &= a_x^3, \\ \Delta &= (f, f')^2 = (ab)^2 a_x b_x, \\ Q &= (f, \Delta)^1 = (ab)^2 (cb) c_x^2 a_x, \\ R &= (\Delta, \Delta')^2 = (ab)^2 (cd)^2 (ac)(bd). \end{aligned}$$

To find the fundamental system of $f + \lambda Q$ we have

$$\begin{aligned} f_{f+\lambda Q} &= f + \lambda Q, \\ \Delta_{f+\lambda Q} &= (f + \lambda Q, f + \lambda Q)^2, \\ &= (f, f')^2 + 2\lambda (f, Q)^2 + \lambda^2 (Q, Q')^2. \end{aligned}$$

To reduce this expression take the first polar of $\Delta = \Delta_x^2$,

$$2\Delta_x \Delta_y = (ab)^2 a_x b_y + (ab)^2 a_y b_x,$$

or

$$\Delta_x \Delta_y = (ab)^2 a_x b_y.$$

Herein, Δ_1, Δ_2 being symbols equivalent to Δ_1, Δ_2 , substitute Δ_1, Δ_2 for $-x_2, x_1$ and multiply by Δ_y , so that

$$(\Delta \Delta') \Delta_y \Delta_y' = (ab)^2 (a \Delta') b_y \Delta_y'.$$

Now

$$\begin{aligned} Q_x^2 &= (f, \Delta)^1 = (a \Delta) a_x^2 \Delta_x, \\ 3Q^2 Q_y &= (a \Delta) (a_x^2 \Delta_y + 2a_x a_y \Delta_x), \\ &= (a \Delta) \{ 3a_x^2 \Delta_y + 2a_x (a_y \Delta_x - a_x \Delta_y) \} \\ &= 3(a \Delta) a_x^2 \Delta_y + 2(xy) (a \Delta)^2 a_x; \end{aligned}$$

and, since it is easy to see that $(f, \Delta)^2 = (a \Delta)^2 a_x$ vanishes identically,

$$Q_x^2 Q_y = (a \Delta) a_x^2 \Delta_y;$$

and, herein writing $b_2, -b_1$ for x_1, x_2 ,

$$(bQ)^2 Q_y = (a \Delta) (ab)^2 \Delta_y;$$

or

$$\begin{aligned} (bQ)^2 b_x Q_x &= (a \Delta) (ab)^2 b_x \Delta_x, \\ &= (\Delta \Delta') \Delta_x \Delta_x = (\Delta, \Delta')^1; \\ \therefore (f, Q)^2 &= 0. \end{aligned}$$

Again, since

$$Q_x^2 Q_y = (a \Delta) a_x^2 \Delta_y,$$

substituting $Q_2', -Q_1'$ for x_1, x_2 ,

$$(QQ')^2 Q_y Q_y' = (a \Delta) (aQ)^2 \Delta_y Q_y'.$$

But

$$\begin{aligned} (f, Q)^2 &= (aQ)^2 a_x Q_x = 0, \\ \therefore (aQ)^2 (a_x Q_y + a_y Q_x) &= 0, \end{aligned}$$

and

$$(aQ)^2 (a_x Q_y - a_y Q_x) = (aQ)^2 (xy);$$

\therefore , by addition,

$$(aQ)^2 a_x Q_y = \frac{1}{2} (aQ)^2 (xy);$$

$$\therefore (a \Delta) (aQ)^2 \Delta_y Q_y = \frac{1}{2} (aQ)^2 \Delta_y^2 = \frac{1}{2} R \cdot \Delta_y^2,$$

since it is quite easy to show that $(aQ)^2 = (\Delta, \Delta')^2$,

$$\therefore (Q, Q')^2 = \frac{1}{2} R \cdot \Delta;$$

and finally

$$\Delta_{f+\lambda Q} = \Delta + \lambda^2 \cdot \frac{1}{2} R \cdot \Delta.$$

Similarly

$$\begin{aligned} Q_{f+\lambda Q} &= (f + \lambda Q, \Delta + \frac{1}{2} \lambda^2 R \Delta)^1, \\ &= (f, \Delta)^1 + \lambda (Q, \Delta)^1 + \frac{1}{2} \lambda^2 R (f, \Delta)^1 + \frac{1}{2} \lambda^2 R (Q, \Delta), \end{aligned}$$

wherein $(f, \Delta)^1 = Q$, and we have to reduce $(Q, \Delta)^1$.

From

$$Q_x^2 Q_y = (\alpha \Delta) \alpha_x^2 \Delta_y,$$

we obtain, substituting $+\Delta_2, -\Delta_1$ for y_1, y_2 ,

$$(Q\Delta) Q_x^2 \Delta_x = (\alpha \Delta) (\Delta \Delta') \alpha_x^2 \Delta_x,$$

or

$$(Q, \Delta)^1 = \frac{1}{2} (\Delta \Delta') \alpha_x^2 \{ (\alpha \Delta) \Delta_x - (\alpha \Delta') \Delta_x \},$$

$$= -\frac{1}{2} (\Delta \Delta') \alpha_x^2 = -\frac{1}{2} R_x f;$$

$$\therefore Q_{f+\lambda Q} = Q \left(1 + \frac{1}{2} \lambda^2 R \right) - \frac{1}{2} R f \left(\lambda + \frac{1}{2} \lambda^2 R \right),$$

$$= \left(1 + \frac{1}{2} \lambda^2 R \right) \left(Q - \frac{1}{2} \lambda R_x f \right).$$

So also it may be shown that

$$R_{f+\lambda Q} = R + \lambda^2 R^2 + \frac{1}{4} \lambda^4 R^3.$$

In general, if $f = \alpha_x^m, \phi = \alpha_x^n$, be any two forms, and any invariant of f be $j = \theta(\alpha_0, \alpha_1, \dots, \alpha_m)$, the corresponding invariant of $f + \lambda \phi$, viz.:

$$j_{f+\lambda \phi} = \theta(\bar{\alpha}_0 + \lambda \bar{\alpha}_0, \bar{\alpha}_1 + \lambda \alpha_1, \dots, \bar{\alpha}_m + \lambda \alpha_m)$$

$$= e^{\lambda \delta} j;$$

where

$$\delta = \bar{\alpha}_0 \frac{\partial}{\partial \alpha_0} + \bar{\alpha}_1 \frac{\partial}{\partial \alpha_1} + \dots + \bar{\alpha}_m \frac{\partial}{\partial \alpha_m}.$$

Now, if j be of degree ν in the coefficients $\bar{\alpha}$, it is a homogeneous function, and may be denoted symbolically by

$$P_a^\nu = (p_0 \alpha_0 + p_1 \alpha_1 + \dots + p_m \alpha_m)^\nu,$$

involving $m+1$ umbrae.

Thence

$$j_{f+\lambda \phi} = e^{\lambda \delta} j = (p_a + \lambda p_a)^\nu = \sum_k \binom{\nu}{k} p_a^{\nu-k} p_a^k;$$

and, comparison of the coefficients of λ^k , gives

$$\frac{1}{k!} (\delta^k j) = \binom{\nu}{k} p_a^{\nu-k} p_a^k = \binom{\nu}{k} (p_a^{\nu-k} p_a^k) / j_a^k,$$

which is simply a numerical multiple of the k^{th} α -polar of j . It must be noticed that (δ^k) denotes an operator of order k , and that it is only equivalent to k successive operations of δ in the particular case when the coefficients $\bar{\alpha}_0, \bar{\alpha}_1, \dots$ are independent of the coefficients $\alpha_0, \alpha_1, \dots$. The operation of δ upon a symbolic product is very simple; suppose Δ to be a symbol which occurs in the product; it may present itself in a determinant factor say $(\Delta \rho)$, or in a power form Δ_x^p . If we find $\delta \Delta_x^m = \psi_x^m$ we write ψ for Δ wherever Δ occurs, and thus obtain one term in the result of the operation; the complete result is obtained by summation in regard to all the symbols dealt with in this manner. The operation of δ upon a transvectant, expressed as such, is precisely similar.

Ex. gr.

$$\text{Let } F_1 = (\alpha b)^2 (\alpha c)^2 (bc)^2,$$

where

$$f = \alpha_x^4, \phi = \alpha_x^4,$$

and

$$\delta \alpha_x^4 = \delta b_x^4 = \delta c_x^4 = \alpha_x^4;$$

then

$$\delta F_1 = (\alpha b)^2 (\alpha c)^2 (bc)^2 + (\alpha a)^2 (\alpha c)^2 (\alpha c)^2 + (\alpha b)^2 (\alpha a)^2 (ba)^2,$$

$$= 3(\alpha b)^2 (\alpha a)^2 (ba)^2.$$

Again let

$$F_2 = \{ (f, f')^2, f''^4 \},$$

where

$$\delta f' = \delta f'' = \delta f''' = \phi;$$

then

$$\delta F_2 = \{ (\phi, f')^2, f''^4 \} + \{ (f, \phi)^2, f''^4 \} + \{ (f, f')^2, \phi^4 \},$$

$$= 3 \{ (f, f')^2, \phi^4 \}.$$

So far we may always go whatever the values of $\bar{\alpha}_0, \bar{\alpha}_1, \dots$ but when these are independent of $\alpha_0, \alpha_1, \dots$ we may introduce new symbols and obtain

$$\delta^2 F_1 = 3(\delta b)^2 (\beta a)^2 (ba)^2 + 3(\alpha \beta)^2 (\alpha a)^2 (\beta a)^2,$$

$$= 6(\alpha \beta)^2 (\alpha a)^2 (\alpha \beta)^2;$$

$$\delta^3 F_1 = 6(\gamma \beta)^2 (\gamma a)^2 (\alpha \beta)^2;$$

so that $e^{\lambda \delta} F_1$

$$= (\alpha b)^2 (\alpha c)^2 (bc)^2 + 3(\alpha b)^2 (\alpha a)^2 (ba) \lambda^2$$

$$+ 3(\alpha \beta)^2 (\alpha a)^2 (\alpha \beta)^2 \lambda^3 + (\beta \gamma)^2 (\alpha \gamma)^2 (\alpha \beta)^2 \lambda^3.$$

Also

$$\delta^2 F_2 = 3 \{ (\phi, f')^2, \phi^4 \} + 3 \{ (f, \phi)^2, \phi^4 \},$$

$$= 6 \{ (\phi, \phi')^2, f''^4 \},$$

$$\delta^3 F_2 = 6 \{ (\phi, \phi')^2, \phi^4 \};$$

leading to

$$e^{\lambda \delta} F_2 = \{ (f, f')^2, f''^4 \} + 3 \{ (f, f')^2, \phi^4 \} \lambda$$

$$+ 3 \{ (\phi, \phi')^2, f''^4 \} \lambda^2 + \{ (\phi, \phi')^2, \phi^4 \} \lambda^3.$$

When, on the other hand, $\bar{\alpha}_0, \bar{\alpha}_1, \dots$ are functions of $\alpha_0, \alpha_1, \dots$ the matter is not so simple, for now (δ^k) an operator of order k is not equivalent to δ^k , k successive operations of δ . Write $\delta = \delta_1$; then $\delta_1^2 = (\delta_1^2) + \delta_1 \delta_1$ when $\delta_1 \delta_1$ is an operator formed by operating upon $\bar{\alpha}_1$ with δ_1 regarding the former merely as a function of $\alpha_0, \alpha_1, \dots$; so that

$$\delta_1 \delta_1 = (\delta_1 \bar{\alpha}_0) \frac{d}{d\alpha_0} + (\delta_1 \bar{\alpha}_1) \frac{d}{d\alpha_1} + \dots;$$

write $\delta_1 \delta_1 = \delta_2$, and generally $\delta_1 \delta_2 = \delta_3$, then it is easy to show that

$$\frac{1}{2!} (\delta_1^2) = \frac{1}{2!} (\delta_1^2 - \delta_2),$$

$$\frac{1}{3!} (\delta_1^3) = \frac{1}{3!} (\delta_1^3 - 3\delta_1 \delta_2 + 2\delta_3),$$

according to a well-known law established by the theorem of operator-transformation given in the section on symmetric functions.

The Partial Differential Equations.—It will be shown later that covariants may be studied by restricting attention to the leading coefficient, viz., that affecting x_1^ϵ where ϵ is the order of the covariant. An important fact, discovered by Cayley, is that these coefficients, and also the complete covariants, satisfy certain partial differential equations which suffice to determine them, and to ascertain many of their properties. These equations can be arrived at in many ways; the method here given is due to Gordan. $\lambda_1, \lambda_2, \mu_1, \mu_2$ being as usual the coefficients of substitution, let

$$\lambda_1 \frac{\partial}{\partial \lambda_1} + \lambda_2 \frac{\partial}{\partial \lambda_2} = D_{\lambda\lambda}, \lambda_1 \frac{\partial}{\partial \mu_1} + \lambda_2 \frac{\partial}{\partial \mu_2} = D_{\lambda\mu},$$

$$\mu_1 \frac{\partial}{\partial \lambda_1} + \mu_2 \frac{\partial}{\partial \lambda_2} = D_{\mu\lambda}, \mu_1 \frac{\partial}{\partial \mu_1} + \mu_2 \frac{\partial}{\partial \mu_2} = D_{\mu\mu},$$

be linear operators. Then if J , J be the original and transformed forms of an invariant

$$J = (\lambda\mu)^{nj},$$

w being the weight of the invariant.

Operation upon J results as follows:—

$$D_{\lambda\lambda} J = wJ; D_{\lambda\mu} J = 0;$$

$$D_{\mu\lambda} J = 0; D_{\mu\mu} J = wJ.$$

The first and fourth of these indicate that $(\lambda\mu)^w$ is a homogeneous function of λ_1, λ_2 , and of μ_1, μ_2 separately, and the second and third arise from the fact that $(\lambda\mu)$ is caused to vanish by both $D_{\lambda\mu}$ and $D_{\mu\lambda}$.

Since $J = F(\bar{A}_0, \bar{A}_1, \dots, \bar{A}_k, \dots)$, where $\bar{A}_k = \alpha_\lambda^{n-k} \alpha_\mu^k$, we find that the results are equivalent to

$$\sum_k (D_{\lambda\lambda} \bar{A}_k) \frac{\partial J}{\partial \bar{A}_k} = wJ; \sum_k (D_{\lambda\mu} \bar{A}_k) \frac{\partial J}{\partial \bar{A}_k} = 0;$$

$$\sum_k (D_{\mu\lambda} \bar{A}_k) \frac{\partial J}{\partial \bar{A}_k} = 0; \sum_k (D_{\mu\mu} \bar{A}_k) \frac{\partial J}{\partial \bar{A}_k} = wJ.$$

According to the well-known law for the changes of independent variables. Now

$$D_{\lambda\lambda} \bar{A}_k = (n-k) \bar{A}_k; D_{\lambda\mu} \bar{A}_k = k \bar{A}_{k-1};$$

$$D_{\mu\lambda} \bar{A}_k = (n-k) \bar{A}_{k+1}; D_{\mu\mu} \bar{A}_k = k \bar{A}_k;$$

so we obtain

$$\sum_k (n-k) \bar{A}_k \frac{\partial J}{\partial \bar{A}_k} = wJ; \sum_k k \bar{A}_{k-1} \frac{\partial J}{\partial \bar{A}_k} = 0;$$

$$\sum_k (n-k) \bar{A}_{k+1} \frac{\partial J}{\partial \bar{A}_k} = 0; \sum_k k \bar{A}_k \frac{\partial J}{\partial \bar{A}_k} = wJ;$$

equations which are valid when $\lambda_1, \lambda_2, \mu_1, \mu_2$ have arbitrary values, and therefore when the values are such that $J = j, \bar{A}_k = \alpha_k$.

Hence

$$n \bar{\alpha}_0 \frac{\partial j}{\partial \alpha_0} + (n-1) \bar{\alpha}_1 \frac{\partial j}{\partial \alpha_1} + (n-2) \bar{\alpha}_2 \frac{\partial j}{\partial \alpha_2} + \dots = wj,$$

$$\bar{\alpha}_0 \frac{\partial j}{\partial \alpha_1} + 2 \bar{\alpha}_1 \frac{\partial j}{\partial \alpha_2} + 3 \bar{\alpha}_2 \frac{\partial j}{\partial \alpha_3} + \dots = 0,$$

$$n \bar{\alpha}_1 \frac{\partial j}{\partial \alpha_0} + (n-1) \bar{\alpha}_2 \frac{\partial j}{\partial \alpha_1} + (n-2) \bar{\alpha}_3 \frac{\partial j}{\partial \alpha_2} + \dots = 0,$$

$$\bar{\alpha}_1 \frac{\partial j}{\partial \alpha_1} + 2 \bar{\alpha}_2 \frac{\partial j}{\partial \alpha_2} + 3 \bar{\alpha}_3 \frac{\partial j}{\partial \alpha_3} + \dots = wj,$$

the complete system of equations satisfied by an invariant. The fourth shows that every term of the invariant is of the same weight. Moreover, if we add the first to the fourth we obtain

$$\sum_k a_k \frac{\partial j}{\partial a_k} = \frac{2w}{n} j = \theta j,$$

where θ is the degree of the invariant; this shows, as we have before observed, that for an invariant

$$w = \frac{1}{2} n \theta.$$

The second and third are those upon the solution of which the theory of the invariant may be said to depend. An instantaneous deduction from the relation $w = \frac{1}{2} n \theta$ is that forms of uneven orders possess only invariants of even degree in the coefficients. The two operators

$$\Omega = \bar{a}_0 \frac{\partial}{\partial a_1} + 2\bar{a}_1 \frac{\partial}{\partial a_2} + \dots + n\bar{a}_{n-1} \frac{\partial}{\partial a_n}$$

$$O = n\bar{a}_1 \frac{\partial}{\partial a_0} + (n-1)\bar{a}_2 \frac{\partial}{\partial a_1} + \dots + \bar{a}_n \frac{\partial}{\partial a_{n-1}}$$

have been much studied by Sylvester, Hammond, Hilbert, and Elliott (Elliott, *l.c.* ch. vi.) It has been established that, if $F(\bar{a}_0, \bar{a}_1, \dots, \bar{a}_n)$ be any rational, integral, homogeneous, and isobaric function of the coefficients,

$$F(\bar{A}_0, \bar{A}_1, \dots, \bar{A}_n) = (\lambda\mu)^w \lambda_1^{n\theta - 2w} \exp \left\{ \frac{\lambda_2}{\lambda_1} O + \frac{\lambda_1 \mu_1}{(\lambda\mu) \Omega} \right\} F(\bar{a}_0, \bar{a}_1, \dots, \bar{a}_n),$$

a result from which all the important facts concerning invariants may be deduced.

The analogous partial differential equations satisfied by any covariant j may be established as follows. We have

$$J = (\lambda\mu)^{w+\epsilon} j$$

where $J = F\{\bar{A}_0, \bar{A}_1, \dots, (x\mu), (\lambda x)\}$
 $j = F(a_0, a_1, \dots, x_1, x_2)$

the new variables being $\xi_1 = (x\mu) = \mu_2 x_1 - \mu_1 x_2$
 $\xi_2 = (\lambda x) = -\lambda_2 x_1 + \lambda_1 x_2.$

We then obtain

$$\sum_k (D_{\lambda\lambda} \bar{A}_k) \frac{\partial J}{\partial \bar{A}_k} + (D_{\lambda\lambda} \xi_2) \frac{\partial J}{\partial \xi_2} = (w + \epsilon) J,$$

$$\sum_k (D_{\lambda\mu} \bar{A}_k) \frac{\partial J}{\partial \bar{A}_k} + (D_{\lambda\mu} \xi_1) \frac{\partial J}{\partial \xi_1} = 0,$$

$$\sum_k (D_{\mu\lambda} \bar{A}_k) \frac{\partial J}{\partial \bar{A}_k} + (D_{\mu\lambda} \xi_2) \frac{\partial J}{\partial \xi_2} = 0,$$

$$\sum_k (D_{\mu\mu} \bar{A}_k) \frac{\partial J}{\partial \bar{A}_k} + (D_{\mu\mu} \xi_1) \frac{\partial J}{\partial \xi_1} = (w + \epsilon) J;$$

or $\sum_k (n-k) \bar{A}_k \frac{\partial J}{\partial \bar{A}_k} + \xi_2 \frac{\partial J}{\partial \xi_2} = (w + \epsilon) J,$

$$\sum_k k \bar{A}_k - 1 \frac{\partial J}{\partial \bar{A}_k} - \xi_2 \frac{\partial J}{\partial \xi_1} = 0,$$

$$\sum_k (n-k) \bar{A}_k + 1 \frac{\partial J}{\partial \bar{A}_k} - \xi_1 \frac{\partial J}{\partial \xi_2} = 0,$$

$$\sum_k k \bar{A}_k \frac{\partial J}{\partial \bar{A}_k} + \xi_1 \frac{\partial J}{\partial \xi_1} = (w + \epsilon) J.$$

Now, as before, we pass from J to j ; further, we make use of the formula

$$\xi_1 \frac{\partial j}{\partial \xi_1} + \xi_2 \frac{\partial j}{\partial \xi_2} = \epsilon j,$$

and we obtain

$$n\bar{a}_0 \frac{\partial j}{\partial a_0} + (n-1)\bar{a}_1 \frac{\partial j}{\partial a_1} + \dots - x_1 \frac{\partial j}{\partial a_1} = wj,$$

$$\bar{a}_0 \frac{\partial j}{\partial a_1} + 2\bar{a}_1 \frac{\partial j}{\partial a_2} + \dots - x_2 \frac{\partial j}{\partial a_1} = 0,$$

$$n\bar{a}_1 \frac{\partial j}{\partial a_0} + (n-1)\bar{a}_2 \frac{\partial j}{\partial a_1} + \dots - x_1 \frac{\partial j}{\partial a_2} = 0,$$

$$\bar{a}_1 \frac{\partial j}{\partial a_1} + 2\bar{a}_2 \frac{\partial j}{\partial a_2} + \dots - x_2 \frac{\partial j}{\partial a_2} = wj;$$

the complete system.

Adding the first and fourth equations we obtain

$$n\theta - \epsilon = 2w,$$

the invariant relation connecting the four numbers n, θ, ϵ, w . The satisfaction of the differential equations is not only necessary, but it is also sufficient. To establish this, in the case of invariants let J be any solution of the differential equations, in which the quantities \bar{A}_k are independent variables, and K any other solution. We obtain

$$\frac{1}{K^2} \left(K \frac{\partial J}{\partial \lambda_1} - J \frac{\partial K}{\partial \lambda_1} \right) \lambda_1 + \frac{1}{K^2} \left(K \frac{\partial J}{\partial \lambda_2} - J \frac{\partial K}{\partial \lambda_2} \right) \lambda_2 = 0,$$

$$\frac{1}{K^2} \left(K \frac{\partial J}{\partial \mu_1} - J \frac{\partial K}{\partial \mu_1} \right) \mu_1 + \frac{1}{K^2} \left(K \frac{\partial J}{\partial \mu_2} - J \frac{\partial K}{\partial \mu_2} \right) \mu_2 = 0,$$

$$\frac{1}{K^2} \left(K \frac{\partial J}{\partial \lambda_1} - J \frac{\partial K}{\partial \lambda_1} \right) \mu_1 + \frac{1}{K^2} \left(K \frac{\partial J}{\partial \lambda_2} - J \frac{\partial K}{\partial \lambda_2} \right) \mu_2 = 0,$$

$$\frac{1}{K^2} \left(K \frac{\partial J}{\partial \mu_1} - J \frac{\partial K}{\partial \mu_1} \right) \mu_1 + \frac{1}{K^2} \left(K \frac{\partial J}{\partial \mu_2} - J \frac{\partial K}{\partial \mu_2} \right) \mu_2 = 0;$$

or, if $J = KL$,

$$\frac{\partial L}{\partial \lambda_1} \lambda_1 + \frac{\partial L}{\partial \lambda_2} \lambda_2 = 0; \quad \frac{\partial L}{\partial \mu_1} \mu_1 + \frac{\partial L}{\partial \mu_2} \mu_2 = 0;$$

$$\frac{\partial L}{\partial \lambda_1} \mu_1 + \frac{\partial L}{\partial \lambda_2} \mu_2 = 0; \quad \frac{\partial L}{\partial \mu_1} \lambda_1 + \frac{\partial L}{\partial \mu_2} \lambda_2 = 0.$$

As $(\lambda\mu)$ does not vanish, these equations necessitate

$$\frac{\partial L}{\partial \lambda_1} = 0; \quad \frac{\partial L}{\partial \mu_1} = 0; \quad \frac{\partial L}{\partial \lambda_2} = 0; \quad \frac{\partial L}{\partial \mu_2} = 0,$$

showing that L is independent of $\lambda_1, \lambda_2, \mu_1, \mu_2$.

We may put $K = (\lambda\mu)^w$ so that

$$J = (\lambda\mu)^w L$$

and now putting $\lambda_1 = \mu_2 = 1, \lambda_2 = \mu_1 = 0, L$ becomes equal to j , and $J = (\lambda\mu)^w j$; hence this relation is satisfied by every solution j of the differential equations. If we have several binary quantics we have similarly the two operations

$$\sum \Omega - x_2 \frac{\partial}{\partial x_1},$$

$$\sum O - x_1 \frac{\partial}{\partial x_2},$$

which cause the vanishing of a covariant and the invariable relation

$$\Sigma n\theta - 2w = \epsilon$$

connecting the numbers $n_1, \theta_1, n_2, \theta_2, \dots, w, \epsilon$.

The Evectant Process.—If we have a symbolic product, which contains the symbol a only in determinant factors such as (ab) , we may write $x_2, -x_1$ for a_1, a_2 , and thus obtain a product in which (ab) is replaced by $b_x, (ac)$ by c_x and so on. In particular, when the product denotes an invariant we may transform each of the symbols a, b, \dots, x in succession, and take the sum of the resultant products; we thus obtain a covariant which is called the first evectant of the original invariant. The second, evectant is obtained by similarly operating upon all the symbols remaining which only occur in determinant factors, and so on for the higher evectants.

Ex. gr. From $(ac)^2 (bd)^2 (ad)(bc)$ we obtain

$$(bd)^2 (bc) c_x^2 d_x + (ac)^2 (ad) c_x d_x^2$$

$$- (bd)^2 (ad) a_x^2 b_x - (ac)^2 (bc) a_x b_x^2$$

$$= 4 (bd)^2 (bc) c_x^2 d_x \text{ the first evectant;}$$

and thence $4c_x^2 d_x^2$ the second evectant; in fact the two evectants are to numerical factors *près*, the cubic covariant Q , and the square of the original cubic.

If θ be the degree of an invariant j

$$\theta j = \bar{a}_0 \frac{\partial j}{\partial a_0} + \bar{a}_1 \frac{\partial j}{\partial a_1} + \dots + \bar{a}_n \frac{\partial j}{\partial a_n}$$

$$= \bar{a}_1^n \frac{\partial j}{\partial a_0} + \bar{a}_1^{n-1} \bar{a}_2 \frac{\partial j}{\partial a_1} + \dots + \bar{a}_2^n \frac{\partial j}{\partial a_n}$$

and, herein transforming from a to x , we obtain the first evectant

$$p_x^n = \sum_k (-)^k x_1^k x_2^{n-k} \frac{\partial j}{\partial a_k}.$$

Combinants.—An important class of invariants, of several binary forms of the same order, was discovered by Sylvester. The invariants in question are invariants *quod* linear transformation of the forms themselves as well as *quod* linear transformation of the variables. If the forms be $a_x^p, b_x^p, c_x^p, \dots$ the Aronhold process, given by the operation δ as between any two of the forms,

causes such an invariant to vanish. Thus it has annihilators of the forms

$$\begin{aligned} \dot{a}_0 \frac{d}{db_0} + \dot{a}_1 \frac{d}{db_1} + \dot{a}_2 \frac{d}{db_2} + \dots \\ \bar{b}_0 \frac{d}{da_0} + \bar{b}_1 \frac{d}{da_1} + \bar{b}_2 \frac{d}{da_2} + \dots \end{aligned}$$

and Gordan, in fact, takes the satisfaction of these conditions as defining those invariants which Sylvester termed "Combinants." The existence of such forms seems to have been brought to Sylvester's notice by observation of the fact that the resultant of a_x^p and b_x^p must be a factor of the resultant of $\lambda a_x^p + \mu b_x^p$ and $\lambda a_x^p + \mu' b_x^p$ for a common factor of the first pair must be also a common factor of the second pair; so that the condition for the existence of such common factor must be the same in the two cases. A leading proposition states that, if an invariant of λa_x^p and μb_x^p be considered as a form in the variables λ and μ , and an invariant of the latter be taken, the result will be a combinant of a_x^p and b_x^p . The idea can be generalized so as to have regard to ternary and higher forms each of the same order and of the same number of variables.

For further information see GORDAN. *Vorlesungen über Invariantentheorie*, B. ii. § 6, Leipzig, 1887; E. B. ELLIOTT. *Algebra of Quantics*, Art. 264, Oxford, 1895.

Associated Forms.—A system of forms, such that every form appertaining to the binary form is expressible as a rational and integral function of the members of the system, is difficult to obtain. If, however, we specify that all forms are to be rational, but not necessarily integral functions, a new system of forms arises which is easily obtainable. A binary form of order n contains n independent constants, three of which by linear transformation can be given determinate values; the remaining $n-3$ coefficients, together with the determinant of transformation, give us $n-2$ parameters, and in consequence one relation must exist between any $n-1$ invariants of the form, and fixing upon $n-2$ invariants every other invariant is a rational function of its members. Similarly regarding x_1, x_2 as additional parameters, we see that every covariant is expressible as a rational function of n fixed covariants. We can so determine these n covariants that every other covariant is expressed in terms of them by a fraction whose denominator is a power of the binary form.

First observe that with $f_x = a_x^n = b_x^n = \dots, f_1 = a_1 a_x^{n-1}, f_2 = a_2 a_x^{n-1}, f_x = f_1 x_1 + f_2 x_2$ we find

$$(ab) = \frac{(af)b_x - (bf)a_x}{f_x}$$

and that thence every symbolic product is equal to a rational function of covariants in the form of a fraction whose denominator is a power of f_x . Making the substitution in any symbolic product the only determinant factors that present themselves in the numerator are of the form $(af), (bf), (cf), \dots$ and every symbol a finally appears in the form

$$\psi_k = (af)^k a_x^{n-k}$$

ψ_k has f as a factor, and may be written $f \cdot u_k$; for, observing that $\psi_0 = f \cdot u_0 = f \cdot u_0$; $\psi_1 = 0 = f \cdot u_1$; where $u_0 = 1, u_1 = 0$,

assume that $\psi_k = (af)^k a_x^{n-k} = f \cdot u_k = a_x^n \cdot u_x^{k(n-2)}$.

Taking the first polar with regard to y

$$\begin{aligned} (n-k)(af)^k a_x^{n-k-1} a_y + k(af)^{k-1} a_x^{n-k} (ab)(n-1)b_x^{n-2} b_y \\ = k(n-2)a_x^n u_x^{kn-2k-1} u_y + n a_x^{n-1} u_y u_x^{k(n-2)}, \end{aligned}$$

and, writing f_2 and $-f_1$ for y_1 and y_2 ,

$$\begin{aligned} (n-k)(af)^{k+1} a_x^{n-k-1} + k(n-1)(ab)(af)^{k-1} (bf)a_x^{n-k} b_x^{n-2} \\ = k(n-2)f \cdot (uf)u_x^{kn-2k-1}. \end{aligned}$$

Moreover the second term on the left contains

$$(af)^{k-2} b_x^{k-2} = \frac{1}{2} \{ (af)^{k-2} b_x^{k-2} - (bf)^{k-2} a_x^{k-2} \},$$

if k be uneven, and

$$(af)^{k-1} b_x^{k-1} = \frac{1}{2} \{ (af)^{k-1} b_x^{k-1} - (bf)^{k-1} a_x^{k-1} \},$$

if k be even; in either case the factor

$$(af)b_x - (bf)a_x = (ab)f,$$

and therefore

$$(n-k)\psi_{k+1} + M \cdot f = k(n-2)f \cdot (uf)u_x^{kn-2k-1};$$

and ψ_{k+1} is seen to be of the form $f \cdot u_{k+1}$.

We may write therefore

$$u_k = \frac{(af)^k a_x^{n-k}}{f}$$

These forms, n in number, are called "associated forms" of f ("Schwesterformen" "formes associées").

Every covariant is rationally expressible by means of the forms f, u_2, u_3, \dots, u_n since, as we have seen, $u_0 = 1, u_1 = 0$. It is easy to find the relations

$$\begin{aligned} u_2 &= \frac{1}{2}(f, f')^2, \\ u_3 &= (f, f')^2, f'' \\ u_4 &= \frac{1}{2}(f, f')^4 \cdot f^2 - \frac{3}{4}\{(f, f')^2\}^2, \end{aligned}$$

and so on.

To exhibit any covariant as a function of u_0, u_1, u_2, \dots take $a_y^n = (a_1 y_1 + a_2 y_2)^n$ and transform it by the substitution

$$\begin{aligned} f_1 y_1 + f_2 y_2 = \xi \text{ where } f_1 = a_1 a_x^{n-1}, f_2 = a_2 a_x^{n-1}, \\ x_2 y_1 - x_1 y_2 = \eta \quad f = f_1 x_1 + f_2 x_2; \end{aligned}$$

thence

$$\begin{aligned} f \cdot y_1 = x_2 \xi + f_2 \eta; f \cdot y_2 = x_2 \xi - f_1 \eta, \\ f \cdot a_y = a_2 \xi + (af)\eta, \end{aligned}$$

and

$$f^{n-1} \cdot a_y^n = u_0 \xi^n + \binom{n}{2} u_2 \xi^{n-2} \eta^2 + \binom{n}{3} u_3 \xi^{n-3} \eta^3 + \dots + u_n \eta^n.$$

Now a covariant of $a_x^n = f$ is obtained from the similar covariant of a_y^n by writing therein x_1, x_2 , for y_1, y_2 and, since y_1, y_2 have been linearly transformed to ξ and η , it is merely necessary to form the covariants in respect of the form $(u_1 \xi + u_2 \eta)^n$, and then division, by the proper power of f , gives the covariant in question as a function of $f, u_0 = 1, u_2, u_3, \dots, u_n$.

Ex. gr., in the case of the binary quartic,

$$\begin{aligned} f^3 \cdot a_y^4 = \xi^4 + 3\Delta \xi^2 \eta^2 + 4k \xi \eta^3 + \left(\frac{1}{2} f^2 - \frac{3}{4} \Delta^2\right) \eta^4 \\ \text{and } j = 6 \begin{vmatrix} \bar{a}_0 & \bar{a}_1 & \bar{a}_2 \\ \alpha_1 & \alpha_2 & \alpha_3 \\ \alpha_2 & \alpha_3 & \alpha_4 \end{vmatrix} = \frac{3}{f^3} \left(\frac{1}{2} \Delta f^2 - \Delta^3 - 2k^2\right); \end{aligned}$$

which is exactly the relation connecting the five ground forms. The above system f, u_2, u_3, \dots, u_n is not, however, for many purposes the most convenient system of associated forms. Writing $(f, f')^{2k} = G_{2k}, ((f, f')^{2k}, f'') = H_{2k+1}$, Hermite and Clebsch have shown that u_s is expressible in terms of the s forms $f, G_2, H_2, G_4, \dots, G_s$ or H_s according as s is even or uneven. Hence, we may take this for an associated system appertaining to a form of order s .

We have

$$\begin{aligned} G_{2k} &= (ab)^{2k} a_x^{n-2k} b_x^{n-2k}, \\ H_{2k+1} &= (ab)^{2k} (ac) a_x^{n-2k-1} b_x^{n-2k-1} c_x; \end{aligned}$$

$$\text{but } f \cdot (ab) = (af)b_x - (bf)a_x; (ac)c_x^{n-1} = (af);$$

$$\therefore G_{2k} \cdot f^{2k} = a_x^{n-2k} b_x^{n-2k} \{ (af)b_x - (bf)a_x \}^{2k},$$

$$H_{2k+1} \cdot f^{2k} = a_x^{n-2k-1} b_x^{n-2k} (af) \{ (af)b_x - (bf)a_x \}^{2k}.$$

Whence expression, by the binomial theorem, gives

$$G_{2k} f^{2k} = u_{2k} f^{2k} - \binom{2k}{1} u_{2k-1} u_1 f^{2k-1} + \binom{2k}{2} u_{2k-2} u_2 f^{2k-2} - \dots + u_{2k} f^{2k},$$

or,

$$G_{2k} \cdot f^{2k-2} = 2 \{ u_{2k} u_0 + \binom{2k}{2} u_{2k-2} u_2 - \binom{2k}{3} u_{2k-3} u_3 + \dots - \frac{1}{2} (-)^k \binom{2k}{k} u_k^2 \};$$

and, similarly,

$$H_{2k+1} \cdot f^{2k-2} = u_{2k+1} u_0 + \frac{2k(2k-3)}{2!} u_{2k-1} u_2 - \dots - (-)^k \binom{2k}{k} u_{k+1} u_k;$$

and, from these, we can express the members of the u system in terms of the G and H system.

As the symbolic expression of forms with two series of cogredient variables, we take

$$\begin{aligned} a_x^m a_y^n &= (a_1 x_1 + a_2 x_2)^m (a_1 y_1 + a_2 y_2)^n, \\ &= \sum \binom{m}{k} \binom{n}{\lambda} \lambda^k a_1^{m-k} a_2^{m-k} a_1^{n-\lambda} a_2^{n-\lambda} x_1^k x_2^{m-k} y_1^\lambda y_2^{n-\lambda}, \end{aligned}$$

the real expression being $\sum \binom{m}{k} \binom{n}{\lambda} \lambda^k a_1^{m-k} a_2^{m-k} a_1^{n-\lambda} a_2^{n-\lambda} x_1^k x_2^{m-k} y_1^\lambda y_2^{n-\lambda}$; the form being of degree m in x_1, x_2 and of degree n in y_1, y_2 , and the coefficients $a_k a_\lambda$ being arbitrary.

It may happen that $a_x^m a_y^n$ is the product of the two forms a_x^m, a_y^n , and then $\bar{a}_k \bar{a}_\lambda = \bar{a} k \cdot \bar{a} \lambda$; this case is included in the general theory.

A symbolic product contains factors of seven types, viz. :-

- (i.) $a_x = b_x = \dots$, (ii.) $a_x = \beta_x = \dots$,
- (iii.) $a_y = b_y = \dots$, (iv.) $a_y = \beta_y = \dots$,
- (v.) (ab) , (vi.) $(a\beta)$, (vii.) $(a\beta)$,

and, if it is to have a real expression, each letter a, b, c, \dots must occur m times, and each letter $\alpha, \beta, \gamma, \dots$ n times. An important proposition is the expression of $a_x^m a_y^n$ in a series of polars of forms, of type $(aa)^\lambda a_x^{m-\lambda} a_y^{n-\lambda}$, each polar being multiplied by a power of (xy) . Gordan's formula is

$$a_x^m a_y^n = \sum_{k=0}^{\min(m,n)} \binom{m}{k} \binom{n}{k} \{ (aa)^k a_x^{m-k} a_y^{n-k} \}_y^{n-k} (xy)^k;$$

and the right-hand side is a simultaneous covariant of the forms $(aa)^k a_x^{m-k} a_y^{n-k}$ which involve but one series of variables.

Other useful series are

$$a_x^\lambda a_y^\mu = \sum_{k=0}^{\min(\lambda,\mu)} \binom{\lambda}{k} \binom{\mu}{k} \{ (aa)^k a_x^{\lambda-k} a_y^{\mu-k} \}_y^{\mu-k} (xy)^k;$$

$$(a_x a_y)^n = \sum_{k=0}^n (-1)^k \binom{m}{k} \binom{n}{k} (aa)^k a_x^{m-k} a_y^{n-k} (xy)^k.$$

As an application consider the second transvectant of the quartic a_x^4 with its Hessian, $(ab)^2 a_x^2 b_x^2 = \Delta_x^4$; Expand a member of the third polar of $(ab)a_x^2 b_x^2$, viz. :-

$$(ab)a_x^2 b_x^2 = (ab) \left\{ a_x^2 b_x^2 \right\}_y^2 + \frac{3}{2} \{ (ab)^2 a_x^2 b_x^2 \}_y (xy) + \frac{9}{10} (ab)^3 \{ a_x b_x \}_y \{ xy \}^2 + \frac{1}{4} (ab)^4 (xy)^3;$$

the first and third terms vanish, and hence

$$(ab)a_x^2 b_x^2 = \frac{3}{2} \{ \Delta_x^4 \}_y (xy) + \frac{1}{4} (ab)^4 (xy)^3.$$

By a previous theorem if we transform from y to c and multiply by c_x , $\{ \Delta_x^4 \}_y (xy)$ becomes $c_x^2 (ac)^2 \Delta_x^2 = (\Delta_x^4, a_x^4)$.

Hence

$$-(ab)(bc)^3 a_x^3 c_x = \frac{3}{2} (\Delta_x^4, a_x^4) + \frac{1}{4} (ab)^4 c_x^4,$$

and

$$-(ab)(bc)^3 a_x^3 c_x = \frac{1}{2} \{ (ac)(bc)^3 a_x^3 b_x - (ab)(bc)^3 a_x^3 c_x \} = \frac{1}{2} (bc)^3 a_x \{ (ac)b_x - (ab)c_x \} = \frac{1}{2} (bc)^4 a_x^4 = \frac{1}{2} (ab)^4 c_x^4.$$

$$\therefore (\Delta_x^4, a_x^4) = \frac{1}{6} (ab)^4 c_x^4 = \frac{1}{6} i \cdot f.$$

Summary of Results.—We will now give a short account of the results to which the foregoing processes lead. Of any form a_x^n there exists a finite number of invariants and covariants, in terms of which all other covariants are rational and integral functions (cf. Gordan, Band ii. § 21). This finite number of forms is said to constitute the complete system. Of two or more binary forms there are also complete systems containing a finite number of forms. There are also algebraic systems, as above mentioned, involving fewer covariants which are such that all other covariants are rationally expressible in terms of them; but these smaller systems do not possess the same mathematical interest as those first mentioned.

The Binary Quadratic.—The complete system consists of the form itself, a_x^2 , and the discriminant, which is the second transvectant of the form upon itself, viz.: $(f, f')^2 = (ab)^2$; or, in real coefficients, $2(\bar{a}_0 \bar{a}_2 - \bar{a}_1^2)$. The first transvectant, $(f, f') = (ab)a_x b_x$, vanishes identically. Calling the discriminant D , the solution of the quadratic $a_x^2 = 0$ is given by the formula

$$a_x^2 = \frac{1}{a_0} \left(\bar{a}_0 x_1 + \bar{a}_1 x_2 - x_2 \sqrt{-\frac{D}{2}} \right) \left(\bar{a}_0 x_1 + \bar{a}_1 x_2 + x_2 \sqrt{-\frac{D}{2}} \right).$$

If the form a_x^2 be written as the product of its linear factors $p_x q_x$ the discriminant takes the form $-\frac{1}{2}(pq)^2$. The vanishing of this invariant is the condition for equal roots. The simultaneous system of two quadratic forms a_x^2, a_x^2 , say f and ϕ , consists of six forms, viz.: the two quadratic forms f, ϕ ; the two discriminants $(f, f')^2, (\phi, \phi')^2$, and the first and second transvectants of f upon ϕ , (f, ϕ) and $(f, \phi)'$, which may be written $(aa)a_x a_x$ and $(aa)'$. These fundamental or ground forms are connected by the relation

$$-2\{(f, \phi)'\}^2 = f^2(\phi, \phi')^2 - 2f\phi(f, \phi) + \phi^2(f, f')^2.$$

If the covariant $(f, \phi)'$ vanishes f and ϕ are clearly proportional and if the second transvectant of $(f, \phi)'$ upon itself vanishes, f and ϕ possess a common linear factor; and the condition is both necessary and sufficient. In this case $(f, \phi)'$ is a perfect square since its discriminant vanishes. If $(f, \phi)'$ be not a perfect square, and r_x, s_x be its linear factors, it is possible to express f and ϕ in the canonical forms $\lambda_1(r_x)^2 + \lambda_2(s_x)^2, \mu_1(r_x)^2 + \mu_2(s_x)^2$ respectively. In fact, if f and ϕ have these forms, it is easy to verify that $(f, \phi)'$ is $(\lambda\mu)(rs)r_x s_x$. The fundamental system connected with n quadratic forms consists of (i.) the n forms themselves f_1, f_2, \dots, f_n , (ii.) the $\binom{n}{2}$ functional determinants $(f_i, f_k)'$, (iii.) the $\binom{n+1}{2}$ invariants $(f_i, f_k)''$, (iv.) the $\binom{n}{3}$ forms $(f_i, f_k, f_m)''$, each such form remaining unaltered for any permutations of i, k, m . Between these forms various relations exist (cf. Gordan, § 134).

The Binary Cubic.—The complete system consists of

$$f = a_x^3, (f, f')^2 = (ab)^2 a_x b_x = \Delta_x^2, (f, \Delta) = (ab)^2 (ca) b_x c_x^2 = Q_x^3,$$

and

$$(\Delta, \Delta')^2 = (ab)^2 (ca)^2 (ad)(bc) = R.$$

To prove that this system is complete we have to consider

$$(f, \Delta)^2, (\Delta, \Delta')^3, (f, Q)^3, (f, Q)^2, (f, Q), (\Delta, Q)^3, (\Delta, Q)^2,$$

and each of these can be shown either to be zero or to be a rational integral function f, Δ, Q and R . These forms are connected by the relation

$$2Q^2 + \Delta^3 + Rf^2 = 0.$$

The discriminant of f is equal to the discriminant of Δ , and is therefore $(\Delta, \Delta')^2 = R$; if it vanishes both f and Δ have two roots equal, Δ is a rational factor of f and Q is a perfect cube; the cube root being equal, to a numerical factor *près*, to the square root of Δ . The Hessian $\Delta = \Delta_x^2$ is such that $(f, \Delta)^2 = 0$, and if f is expressible in the form $\lambda(p_x)^2 + \mu(q_x)^2$, that is as the sum of two perfect cubes, we find that Δ_x^2 must be equal to $p_x q_x$ for then

$$\{\lambda(p_x)^2 + \mu(q_x)^2, p_x q_x\} = 0.$$

Hence, if p_x, q_x be the linear factors of the Hessian Δ_x^2 , the cubic can be put into the form $\lambda(p_x)^2 + \mu(q_x)^2$ and immediately solved. This method of solution fails when the discriminant R vanishes, for then the Hessian has equal roots, as also the cubic f . The Hessian in that case is a factor of f , and Q is the third power of the linear factor which occurs to the second power in f . If, moreover, Δ vanishes identically f is a perfect cube.

The Binary Quartic.—The fundamental system consists of five forms $a_x^4 = f; (f, f')^2 = (ab)^2 a_x^2 b_x^2 = \Delta_x^4; (f, f')^4 = (ab)^4 = i; (f, \Delta)^4 = (a\Delta) a_x^2 \Delta_x^2 = (ab)^2 (cb) a_x^2 b_x c_x^2 = t; (f, \Delta)^4 = (a\Delta)^4 = (ab)^2 (bc)^2 (ca)^2 = j$, viz., two invariants, two quartics, and a sextic. They are connected by the relation

$$2t^2 = \frac{1}{2} i f^2 \Delta - \Delta^3 - \frac{1}{3} j f^3.$$

The discriminant, whose vanishing is the condition that f may possess two equal roots, has the expression $f^2 - \frac{1}{6} t^2$; it is nine

times the discriminant of the cubic resolvent $k^3 - \frac{1}{2} i k - \frac{1}{3} j$, and

has also the expression $4(t, t')^2$. The quartic has four equal roots, that is to say, is a perfect fourth power, when the Hessian vanishes identically; and conversely. This can be verified by equating to zero the five coefficients of the Hessian $(ab)^2 a_x^2 b_x^2$. Gordan has also shown that the vanishing of the Hessian of the binary n^{th} is the necessary and sufficient condition to ensure the form being a perfect n^{th} power. The vanishing of the invariants i and j is the necessary and sufficient condition to ensure the quartic having three equal roots. On the one hand, assuming the quartic to have the form $4a_1^2 x^2$, we find $i = j = 0$, and on the other hand, assuming $i = j = 0$, we find that the quartic must have the form

$a_0 x^4 + 4a_1 x^3 x_2$ which proves the proposition. The quartic will have two pairs of equal roots, that is, will be a perfect square, if it and its Hessian merely differ by a numerical factor. For it is easy to establish the formula $(yx)^2 \Delta_x^4 = 2f \cdot f_y^2 - 2(f_y')^2$ connecting the Hessian with the quartic and its first and second polars; now a , a root of f , is also a root of Δ_x^4 , and consequently the first

polar $f_y = y_1 \frac{\partial f}{\partial x_1} + y_2 \frac{\partial f}{\partial x_2}$ must also vanish for the root a , and thence

$\frac{\partial f}{\partial x_1}$ and $\frac{\partial f}{\partial x_2}$ must also vanish for the same root; which proves that a is a double root of f , and f therefore a perfect square.

When $f = 6a_1^2 x_1^2$ it will be found that $\Delta = -f$. The simplest form

to which the quartic is in general reducible is $f = x_1^4 + 6mx_1^2x_2^2 + x_2^4$, involving one parameter m ; then $\Delta_x^2 = 2m(x_1^4 + x_2^4) + 2(1 - 3m^2)x_1^2x_2^2$; $i = 2(1 + 3m^2)$; $j = 6m(1 - m)^2$; $t = (1 - 9m^2)(x_1^2 - x_2^2)(x_1 + x_2)x_1x_2$. The sextic covariant t is seen to be factorizable into three quadratic factors $\phi = x_1x_2$, $\psi = x_1^2 + x_2^2$, $\chi = x_1^2 - x_2^2$, which are such that the three mutual second transvectants vanish identically; they are for this reason termed conjugate quadratic factors. It is on a consideration of these factors of t that Cayley bases his solution of the quartic equation. For, since $-2t^2 = \Delta^3 - \frac{1}{2}i^2f^2\Delta - \frac{1}{3}j(f-f)^3$, he compares the right-hand side with the cubic resolvent $k^3 - \frac{1}{2}ik^2\lambda - \frac{1}{3}j\lambda^3$, of $f=0$, and notices that they become identical on substituting Δ for k , and $-f$ for λ ; hence, if k_1, k_2, k_3 be the roots of the resolvent,

$$-2t^2 = (\Delta + k_1f)(\Delta + k_2f)(\Delta + k_3f);$$

and now, if all the roots of f be different, so also are those of the resolvent, since the latter, and f , have practically the same discriminant; consequently each of the three factors, of $-2t^2$, must be perfect squares and taking the square root

$$t = \frac{1}{\sqrt{-2}}\phi \cdot \chi \cdot \psi;$$

and it can be shown that ϕ, χ, ψ are the three conjugate quadratic factors of t above mentioned. We have $\Delta + k_1f = \phi^2$, $\Delta + k_2f = \chi^2$, $\Delta + k_3f = \psi^2$, and Cayley shows that a root of the quartic can be expressed in the determinant form

$\begin{vmatrix} 1, k_1, \phi_y^1 \\ 1, k_2, \chi_y^1 \\ 1, k_3, \psi_y^1 \end{vmatrix}$	the remaining roots being obtained by varying the signs which occur in the radicals $\phi_y^1, \chi_y^1, \psi_y^1$. The transformation to the normal form reduces the quartic to a quadratic. The new variables are the linear factors of ϕ . $y_1 = 0$ $y_2 = 1$ If $\phi = r_x \cdot s_x$, the normal form of a_x^4 can be shown to be given by
--	--

$$(rs)^4 \cdot a_x^4 = (ar)^4 s_x^4 + 6(ar)^2 (as)^2 r_x^2 s_x^2 + (as)^4 r_x^4;$$

ϕ is any one of the conjugate quadratic factors of t , so that, in determining r_x, s_x from $\sqrt{\Delta + k_1f} = 0$, k_1 is any root of the resolvent. The transformation to the normal form, by the solution of a cubic and a quadratic, therefore, supplies a solution of the quartic. If $(\lambda\mu)$ is the modulus of the transformation by which a_x^4 is reduced to the normal form, i becomes $(\lambda\mu)^4i$, and $j, (\lambda\mu)^6j$; hence $\frac{i^3}{j^2}$ is absolutely unaltered by transformation, and is termed the absolute invariant. Since therefore $\frac{i^3}{j^2} = \frac{2(1+3m^2)^3}{9m^2(1-m^2)^2}$ we have a cubic equation for determining m^2 as a function of the absolute invariant.

Remark.—Hermite has shown (*Crelle*, Bd. lii.) that the substitution, $z = \frac{i}{j} \frac{\Delta}{f^2}$, reduces $\frac{x_2 \partial x_1 - x_1 \partial x_2}{\sqrt{f}}$ to the form

$$\frac{1}{2i} \sqrt{-\frac{j}{2}} \frac{\partial z}{\sqrt{\frac{1}{3} - \frac{1}{2}z + \frac{j^2}{3^2}z^3}}$$

The Binary Quintic.—The complete system consists of 23 forms, of which the simplest are $f = a_x^5$; the Hessian $H = (f, f'')^2 = (ab)^2 a_x^2 b_x^3$; the quadratic covariant $i = (f, f''')^4 = (ab)^4 a_x b_x$; and the nonic covariant $T = (f, (f', f''')^2)^1 = (f, H)^1 = (aH) a_x^4 H_x^5 = (ab)^2 (ca) a_x^2 b_x^3 c_x^4$; the remaining 19 are expressible as transvectants of compounds of these four.

- There are four invariants $(i, i')^2, (i^3, H)^6, (f^2, i^5)^{10}, (f, i^7)^{14}$
- four linear forms $(f, i^2)^4, (f, i^3)^5, (i^4, T)^8, (i^5, T)^9$
- three quadratic forms $i, (H, i^2)^4, (H, i^3)^5$
- three cubic forms $(f, i)^2, (f, i^2)^3, (i^3, T)^6$
- two quartic forms $(H, i)^3, (H, i^2)^4$
- three quintic forms $f, (f, i)^1, (i^2, T)^4$
- two sextic forms $H, (H, i)^2$
- one septic form $(i, T)^2$
- one nonic form T .

We will write the cubic covariant $(f, i)^2 = j$, and then remark that the result, $(f, j)^3 = 0$, can be readily established. The form j is completely defined by the relation $(f, j)^3 = 0$ as no other covariant possesses this property.

Certain covariants of the quintic involve the same determinant factors as appeared in the system of the quartic; these are f, H, i, T , and j , and are of special importance. Further, it is convenient to have before us two other quadratic covariants, viz.,

$\tau = (j, j')^2_{j_x j_x}$; $\theta = (i\tau) i_x \tau_x$; four other linear covariants, viz., $\alpha = -(ji)^2_{j_x}$; $\beta = (i\alpha) i_x$; $\gamma = (\tau\alpha) \tau_x$; $\delta = (\tau\beta) \tau_x$. Further, in the case of invariants, we write $A = (i, i')^2$ and take three new forms $B = (i, \tau)^2$; $C = (\tau, \tau')^2$; $R = (\beta\gamma)$. Hermite expresses the quintic in a *forme-type* in which the constants are invariants and the variables linear covariants. If α, β be the linear forms, above defined, he raises the identity $\alpha_x(\alpha\beta) = \alpha_x(\alpha\beta) - \beta_x(\alpha\alpha)$ to the fifth power (and in general to the power n) obtaining

$$(\alpha\beta)^5 f = (\alpha\beta)^5 a_x^5 - 5(\alpha\beta)^4 (\alpha\alpha) a_x^4 \beta_x + \dots - (\alpha\alpha)^5 \beta_x^5;$$

and then expresses the coefficients, on the right, in terms of the fundamental invariants. On this principle the covariant j is expressible in the form

$$R^2 j = \delta^3 + \frac{3}{2} B \delta^2 \alpha + \frac{3}{4} A C \delta \alpha^2 + \frac{3}{8} C (3AB - 4C) \alpha^3$$

when δ, α are the above defined linear forms.

Hence, solving the cubic,

$$R^2 j = (\delta - m_1 \alpha)(\delta - m_2 \alpha)(\delta - m_3 \alpha)$$

wherein m_1, m_2, m_3 are invariants.

Sylvester showed that the quintic might, in general, be expressed as the sum of three fifth powers, viz., in the canonical form $f = k_1(p_x)^5 + k_2(q_x)^5 + k_3(r_x)^5$. Now, evidently, the third transvectant of f , expressed in this form, with the cubic $p_x q_x r_x$ is zero, and hence from a property of the covariant j we must have $j = p_x q_x r_x$; showing that the linear forms involved are the linear factors of j . We may therefore write

$$f = k_1(\delta - m_1 \alpha)^5 + k_2(\delta - m_2 \alpha)^5 + k_3(\delta - m_3 \alpha)^5;$$

and we have merely to determine the constants k_1, k_2, k_3 . To determine them notice that $R = (\alpha\delta)$ and then

$$\begin{aligned} (f, \alpha^5)^5 &= -R^5(k_1 + k_2 + k_3), \\ (f, \alpha^4 \delta)^5 &= -5R^5(m_1 k_1 + m_2 k_2 + m_3 k_3), \\ (f, \alpha^3 \delta^2)^5 &= -10R^5(m_1^2 k_1 + m_2^2 k_2 + m_3^2 k_3), \end{aligned}$$

three equations for determining k_1, k_2, k_3 . This canonical form depends upon j having three unequal linear factors. When C vanishes j has the form $j = p_x^2 q_x$, and $(f, j)^5 = (\alpha p)^2 (\alpha q) a_x^2 = 0$.

Hence, from the identity $\alpha_x(pq) = p_x(\alpha q) - q_x(\alpha p)$, we obtain $(pq)^5 f = (\alpha q)^5 p_x^2 - 5(\alpha p)(\alpha q)^4 p_x q_x - (\alpha p)^5 q_x^2$, the required canonical form. Now, when $C=0$, clearly (see *ante*) $R^2 j = \delta^2 \rho$ where $\rho = \delta + \frac{3}{2} B \alpha$; and Gordan then proves the relation

$$6R^4 \cdot f = B \delta^5 + 5B \delta^4 \rho - 4A^2 \rho^5,$$

which is Bring's form of quintic at which we can always arrive, by linear transformation, whenever the invariant C vanishes.

Remark.—The invariant C is a numerical multiple of the resultant of the covariants i and j , and if $C=0$, ρ is the common factor of i and j .

The discriminant is the resultant of $\frac{\partial f}{\partial x_1}$ and $\frac{\partial f}{\partial x_2}$ and of degree 8 in the coefficients; since it is a rational and integral function of the fundamental invariants it is expressible as a linear function of A^2 and B ; it is independent of C , and is therefore unaltered when C vanishes; we may therefore take f in the canonical form

$$6R^4 f = B \delta^5 + 5B \delta^4 \rho - 4A^2 \rho^5.$$

The two equations

$$\begin{aligned} \frac{\partial f}{\partial \delta} &= 5(B \delta^4 + 4B \delta^3 \rho) = 0, \\ \frac{\partial f}{\partial \rho} &= 5(B \delta^4 - 4A^2 \rho^4) = 0, \end{aligned}$$

yield by elimination of δ and ρ the discriminant

$$D = 64B - A^2.$$

The general equation of degree 5 cannot be solved algebraically, but the roots can be expressed by means of elliptic modular functions. For an algebraic solution the invariants must fulfil certain conditions. When $R=0$, and neither of the expressions $AC - B^2$; $2AB - 3C$ vanishes, the covariant α_x is a linear factor of f ; but, when $R=AC - B^2 = 2AB - 3C=0$, α_x also vanishes, and then f is the product of the form j_x^3 and of the Hessian of j_x^3 . When α_x and the invariants B and C all vanish, either A or j must vanish; in the former case j is a perfect cube, its Hessian vanishing, and further f contains j as a factor; in the latter case, if ρ_x, σ_x be the linear factors of i, f can be expressed as $(\rho\sigma)^3 f = c_1 \rho_x^5 + c_2 \sigma_x^5$; if both A and j vanish i also vanishes identically, and so also does f . If, however, the condition be the vanishing of i, f contains a linear factor to the fourth power.

The Binary Sextic.—The complete system consists of 26 forms, of which the simplest are $f = a_6^6$; the Hessian $H = (ab)^2 a_2^2 b_2^2$; the quartic $i = (ab)^4 a_2^2 b_2^2$; the covariants $l = (ai)^4 a_2^2$; $T = (ab)^2 (cb) a_2^2 b_2^2 c_2^2$; and the invariants $A = (ab)^3$; $B = (i^2)^2$. There are

- 5 invariants: $(a, b)^6, (i, i')^4, (l, l')^2, (f, f')^6, ((f, i), l^4)^2$;
- 6 of order 2: $l, (i, l)^2, (f, f')^4, (i, l')^2, (f, f')^2, ((f, i), l^2)^2$;
- 5 of order 4: $i, (f, l)^2, (i, l), (f, l')^2, ((f, i), l^2)^2$;
- 5 of order 6: $f, p = (ai)^2 a_2^2 b_2^2 c_2^2, (f, l), ((f, i), l)^2, (p, l)$;
- 3 of order 8: $H, (f, i), (H, l)$;
- 1 of order 10: (H, i) ;
- 1 of order 12: T .

For a further discussion of the binary sextic see Gordan *loc. cit.*, Clebsch *loc. cit.* The complete systems of the quintic and sextic were first obtained by Gordan in 1868 (*Journ. f. Math.* lxxix. 323-354). Von Gall in 1880 obtained the complete system of the binary octavic (*Math. Ann.* xvii. 31-52, 139-152, 456); and, in 1888, that of the binary septimic, which proved to be much more complicated (*Math. Ann.* xxxi. 318-336). Single binary forms of higher and finite order have not been studied with complete success, but the system of the binary form of infinite order has been completely determined by Sylvester, Cayley, MacMahon, and Stroh, each of whom contributed to the theory.

As regards simultaneous binary forms, the system of two quadratics, and of any number of quadratics, is alluded to above, and has long been known. The system of the quadratic and cubic, consisting of 15 forms, and that of two cubics, consisting of 26 forms, were obtained by Salmon and Clebsch; that of the cubic and quartic we owe to Gundelfinger (*Programm Stuttgart*, 1869, 1-43); that of the quadratic and quintic to Winter (*Programm Darmstadt*, 1880); that of the quadratic and sextic to von Gall (*Programm Lemgo*, 1873); that of two quartics to Gordan (*Math. Ann.* ii. 227-281, 1870); and to Bertini (*Batt. Giorn.* xiv. 1-14, 1876; also *Math. Ann.*, xi. 30-41, 1877). The system of four forms, of two of which two and two quadratic, has been investigated by Perrin (*S. M. F. Bull.* xv. 45-61, 1887).

Ternary and Higher Forms.—The ternary form of order n is represented symbolically by

$$(a_1 x_1 + a_2 x_2 + a_3 x_3)^n = a_n^n;$$

and, as usual, b, c, d, \dots are alternative symbols, so that

$$a_n^n = b_n^n = c_n^n = d_n^n = \dots$$

To form an invariant or covariant we have merely to form a product of factors of two kinds, viz. determinant factors $(abc), (abd), (bce), \dots$, and other factors a_2, b_2, c_2, \dots in such manner, that each of the symbols a, b, c, \dots occurs n times. Such a symbolic product, if it does not vanish identically, denotes an invariant or a covariant, according as factors a_2, b_2, c_2, \dots do not or do appear. To obtain the real form we multiply out, and, in the result, substitute for the products of symbols the real coefficients which they denote.

For example, take the ternary quadratic

$$(a_1 x_1 + a_2 x_2 + a_3 x_3)^2 = a_2^2,$$

or in real form $ax^2 + bx^2 + cx^2 + 2fx_2 x_3 + 2gx_2 x_1 + 2hx_2 x_3$. We can see that $(abc) a_2 b_2 c_2$ is not a covariant, because it vanishes identically, the interchange of a and b changing its sign instead of leaving it unchanged; but $(abc)^2$ is an invariant. If a_2^2, b_2^2, c_2^2 be different forms we obtain, after development of the squared determinant and conversion to the real form (employing single and double dashes to distinguish the real coefficients of b_2^2 and c_2^2),

$$\begin{aligned} & a(b'c'' + b''c') - 2f'f'' + b(c'a'' + c'a') - 2g'g'' \\ & + c(a'b'' + a''b') - 2h'h'' + 2f'(g'h'' + g''h') - a'f'' - a''f' \\ & + 2g(h'f'' + h''f') - b'g'' - b''g' + 2h(f'g'' + f''g') - c'h'' - c'h'; \end{aligned}$$

a simultaneous invariant of the three forms, and now suppressing the dashes we obtain

$$6(abc + 2fgh - af^2 - bg^2 - ch^2),$$

the expression in brackets being the well-known invariant of a_2^2 , the vanishing of which expresses the condition that the form may break up into two linear factors, or, geometrically, that the conic may represent two right lines. The complete system consists of the form itself and this invariant.

The ternary cubic has been investigated by Cayley, Aronhold, Hermite, Brioschi, and Gordan. The principal reference is to Gordan (*Math. Ann.* i. 90-128, 1869, and vi. 436-512, 1873). The complete covariant and contravariant system includes no fewer than 34 forms; from its complexity it is desirable to consider the cubic in a simple canonical form; that chosen by Cayley was

$ax^3 + by^3 + cz^3 + 6dxyz$ (*Amer. J. Math.* iv. 1-16, 1881). Another form, associated with the theory of elliptic functions, has been considered by Dingley (*Math. Ann.* xxxi. 157-176, 1888), viz. $xy^2 - 4x^2 + g_2 x^2 y + g_3 x^3$, and also the special form $axx^2 - 4by^3$ of the cuspidal cubic. An investigation, by non-symbolic methods, is due to Mertens (*Wien. Ber.* xc. 942-991, 1887). Hesse showed independently that the general ternary cubic can be reduced, by linear transformation, to the form

$$x^3 + y^3 + z^3 + 6mxyz,$$

a form which involves 9 independent constants, as should be the case; it must, however, be remarked that the counting of constants is not a sure guide to the existence of a conjectured canonical form. Thus the ternary quartic is not, in general, expressible as a sum of five 4th powers as the counting of constants might have led one to expect, a theorem due to Sylvester. Hesse's canonical form shows at once that there cannot be more than two independent invariants; for if there were three we could, by elimination of the modulus of transformation, obtain two functions of the coefficients equal to functions of m , and thus, by elimination of m , obtain a relation between the coefficients, showing them not to be independent, which is contrary to the hypothesis.

The simplest invariant is $S \equiv (abc)(abd)(acd)(bcd)$ of degree 4, which for the canonical form of Hesse is $m(1 - m^3)$; its vanishing indicates that the form is expressible as a sum of three cubes.

The Hessian is symbolically $(abc)^2 a_2 b_2 c_2 = H_2^3$, and for the canonical form $(1 + 2m^3)xyz - m^2(x^3 + y^3 + z^3)$. By the process of Aronhold we can form the invariant S for the cubic $a_2^3 + \lambda H_2^3$, and then the coefficient of λ is the second invariant T . Its symbolic expression, to a numerical factor *près*, is

$$(Hbc)(Hbd)(Hcd)(bcd),$$

and it is clearly of degree 6.

One more covariant is requisite to make an algebraically complete set. This is of degree 8 in the coefficients, and degree 6 in the variables, and, for the canonical form, has the expression

$$\begin{aligned} & -9m^2(x^3 + y^3 + z^3)^2 - (2m + 5m^4 + 20m^7)(x^3 + y^3 + z^3)xyz \\ & - (15m^2 + 78m^5 - 12m^8)x^2 y^2 z^2 + (1 + 8m^3)^2 (y^2 z^2 + z^2 x^2 + x^2 y^2). \end{aligned}$$

Passing on to the ternary quartic we find that the number of ground forms is apparently very great. Gordan (*Math. Ann.* xvii. 217-233), limiting himself to a particular case of the form, has determined 54 ground forms, and Maisano (*Batt. G.* xix. 198-237, 1881) has determined all up to and including the 5th degree in the coefficients.

The system of two ternary quadratics consists of 20 forms; it has been investigated by Gordan (*Clebsch-Lindemann's Vorlesungen*, i. 288, also *Math. Ann.* xix. 529-552); Perrin (*S. M. F. Bull.* xviii. 1-80, 1890); Rosanes (*Math. Ann.* vi. 264); and Gerbaldi (*Annali* (2), xvii. 161-196).

Ciamberlini has found a system of 127 forms appertaining to three ternary quadratics (*Batt. G.* xxiv. 141-157).

Forsyth has discussed the algebraically complete sets of ground forms of ternary and quaternary forms (see *Amer. J.* xii. 1-60, 115-160, and *Camb. Phil. Trans.* xiv. 409-466, 1889). He proves, by means of the six linear partial differential equations satisfied by the concomitants, that, if any concomitant be expanded in powers of x_1, x_2, x_3 , the point variables—and of u_1, u_2, u_3 , the contra-gradient line variables—it is completely determinate if its leading coefficient be known. For the unipartite ternary quantic of order

n he finds that the fundamental system contains $\frac{1}{2}(n+4)(n-1)$

individuals. He successfully considers the systems of two and three simultaneous ternary quadratics. In Part III. of the Memoir he discusses bi-ternary quantics, and in particular those which are lineo-linear, quadrato-linear, cubo-linear, quadrato-quadratic, cubo-cubic, and the system of two lineo-linear quantics. He shows that the system of the bi-ternary n^m ic comprises

$$\frac{1}{4}(n+1)(n+2)(m+1)(m+2) - 3 \text{ individuals.}$$

Bibliographical references to ternary forms are given by Forsyth (*Amer. J.* xii. p. 16), and by Cayley (*Amer. J.* iv. 1881).

IV. ENUMERATING GENERATING FUNCTIONS.

Professor Michael Roberts (*Quart. Math. J.* iv.) was the first to remark that the study of covariants may be reduced to the study of their leading coefficients, and that from any relations connecting the latter are immediately derivable the relations connecting the former. It has been shown above that a covariant, in general, satisfies four partial differential equations. Two of these show that the leading coefficient of any covariant is an isobaric and homogeneous function of the coefficients of the form; the remaining two may be regarded as operators which cause the

vanishing of the covariant. These may be written, for the binary n^{ic} ,

$$\sum k a_{k-1} \frac{d}{da_k} - x_2 \frac{d}{dx_1} = 0,$$

$$\sum (n-k) a_{k+1} \frac{d}{da_k} - x_1 \frac{d}{dx_2} = 0;$$

or in the form

$$\Omega - x_2 \frac{d}{dx_1} = 0, \quad 0 - x_1 \frac{d}{dx_2} = 0;$$

where

$$\Omega = a_0 \frac{d}{da_1} + 2a_1 \frac{d}{da_2} + \dots + na_{n-1} \frac{d}{da_n},$$

$$0 = na_1 \frac{d}{da_0} + (n-1)a_2 \frac{d}{da_1} + \dots + a_n \frac{d}{da_{n-1}}.$$

Let a covariant of degree ϵ in the variables, and of degree θ in the coefficients (the weight of the leading coefficient being w and $n\theta - \epsilon w = 2$), be

$$C_0 x_1^\epsilon + \epsilon C_1 x_1^{\epsilon-1} x_2 + \dots$$

Operating with $\Omega - x_2 \frac{d}{dx_1}$ we find $\Omega C_0 = 0$; that is to say, C_0 satisfies one of the two partial differential equations satisfied by an invariant. It is for this reason called a seminvariant, and every seminvariant is the leading coefficient of a covariant. The whole theory of invariants of a binary form depends upon the solutions of the equation $\Omega = 0$. Before discussing these it is best to transform the binary form by substituting $1! a_1, 2! a_2, 3! a_3, \dots, n! a_n$, for $a_1, a_2, a_3, \dots, a_n$ respectively; it then becomes

$$a_0 x_1^n + n a_1 x_1^{n-1} x_2 + n(n-1) a_2 x_1^{n-2} x_2^2 + \dots + n! a_n x_2^n,$$

and Ω takes the simpler form

$$a_0 \frac{d}{da_1} + a_1 \frac{d}{da_2} + a_2 \frac{d}{da_3} + \dots + a_{n-1} \frac{d}{da_n}.$$

One advantage we have obtained is that, if we now write $a_0 = 0$, and substitute a_{s-1} for a_s when $s > 0$, we obtain

$$a_0 \frac{d}{da_1} + a_1 \frac{d}{da_2} + a_2 \frac{d}{da_3} + \dots + a_{n-2} \frac{d}{da_{n-1}}$$

which is the form of Ω for a binary $n-1^{\text{ic}}$.

Hence, by merely diminishing each suffix in a seminvariant by unity, we obtain another seminvariant of the same degree, and of weight $w - \theta$, appertaining to the $n-1^{\text{ic}}$. Also, if we increase each suffix in a seminvariant, we obtain terms, free from a_0 , of some seminvariant of degree θ and weight $w + \theta$. *Ex. gr.* from the invariant $a_2^2 - 2a_1 a_3 + 2a_0 a_4$ of the quartic the diminishing process yields $a_1^2 - 2a_0 a_2$, the leading coefficient of the Hessian of the cubic, and the increasing process leads to $a_3^2 - 2a_2 a_4 + 2a_1 a_5$ which only requires the additional term $-2a_0 a_3$ to become a seminvariant of the sextic. A more important advantage, springing from the new form of Ω , arises from the fact that if

$$x^n - a_1 x^{n-1} + a_2 x^{n-2} - \dots + (-)^n a_n = (x - a_1)(x - a_2) \dots (x - a_n),$$

the sums of powers $\Sigma a^2, \Sigma a^3, \Sigma a^4, \dots, \Sigma a^n$ all satisfy the equation $\Omega = 0$. Hence, excluding a_0 , we may, in partition notation, write down the fundamental solutions of the equation, viz.—

$$(2), (3), (4), \dots, (n),$$

and say that, with a_0 , we have an algebraically complete system. Every symmetric function denoted by partitions, not involving the figure unity (say a non-unitary symmetric function), which remains unchanged by any increase of n , is also a seminvariant, and we may take if we please another fundamental system, viz.—

$$a_0, (2), (3), (22), (32), \dots, (2^n) \text{ or } (32^3(n-3)).$$

Observe that, if we subject any symmetric function ($p_1 p_2 p_3 \dots$) to the diminishing process, it becomes $a_0^{p_1 - p_2} (p_2 p_3 \dots)$.

Next consider the solutions of $\Omega = 0$ which are of degree θ and weight w . The general term in a solution involves the product $a_0^{n_0} a_1^{n_1} a_2^{n_2} \dots a_n^{n_n}$ wherein $\Sigma n_i = \theta, \Sigma n_i a_i = w$; the number of such products that may appear depends upon the number of partitions of w into θ or fewer parts limited not to exceed n in magnitude. Let this number be denoted by $(w; \theta, n)$. In order to obtain the seminvariants we would write down the $(w; \theta, n)$ terms each associated with a literal coefficient; if we now operate with Ω we obtain a linear function of $(w-1; \theta, n)$ products, for the vanishing of which the literal coefficients must satisfy $(w-1; \theta, n)$ linear equations; hence $(w; \theta, n) - (w-1; \theta, n)$ of these coefficients may be assumed arbitrarily, and the number of linearly independent solutions of $\Omega = 0$, of the given degree and weight, is precisely $(w; \theta, n) - (w-1; \theta, n)$. This theory is due to Cayley; its validity depends upon showing that the $(w-1; \theta, n)$ linear equations satisfied by the literal coefficients are independent; this has only

recently been established by E. B. Elliott. These seminvariants are said to form an aszygetic system. It is shown in the Article on COMBINATORIAL ANALYSIS that $(w; \theta, n)$ is the coefficient of $a^\theta z^w$ in the ascending expansion of the fraction

$$\frac{1}{1 - a \cdot 1 - az \cdot 1 - az^2 \dots 1 - az^n}.$$

Hence $(w; \theta, n) - (w-1; \theta, n)$ is given by the coefficient of $a^\theta z^w$ in the fraction

$$\frac{1-z}{1 - a \cdot 1 - az \cdot 1 - az^2 \dots 1 - az^n}.$$

the enumerating generating function of aszygetic seminvariants. We may, by a well-known theorem, write the result as a coefficient of z^w in the expansion of

$$\frac{1 - z^{n+1} \cdot 1 - z^{n+2} \dots 1 - z^{n+\theta}}{1 - z^2 \cdot 1 - z^3 \dots 1 - z^\theta};$$

and since this expression is unaltered by the interchange of n and θ we prove Hermite's Law of Reciprocity, which states that the aszygetic forms of degree θ for the n^{ic} are equinumerous with those of degree n for the θ^{ic} .

The degree of the covariant in the variables is $\epsilon = n\theta - 2w$; consequently we are only concerned with positive terms in the developments and $(w, \theta, n) - (w-1; \theta, n)$ will be negative unless $n\theta - 2w \geq 0$. It is convenient to enumerate the seminvariants of degree θ and order $\epsilon = n\theta - 2w$ by a generating function; so, in the first written generating function for seminvariants, write $\frac{1}{z^2}$ for z and az^n for a ; we obtain

$$\frac{1 - z^{-2}}{1 - az^n \cdot 1 - az^{n-2} \cdot 1 - az^{n-4} \dots 1 - az^{n+\theta} \cdot 1 - az^{n+2} \cdot 1 - az^n}$$

in which we have to take the coefficient of $a^\theta z^{n\theta - 2w}$, the expansion being in ascending powers of a . As we have to do only with that part of the expansion which involves positive powers of z , we must try to isolate that portion, say $A_n(z)$. For $n=2$ we can prove that the complete function may be written

$$A_2(z) = \frac{1}{z^2} A_2 \left(\frac{1}{z} \right),$$

where

$$A_2(z) = \frac{1}{1 - az^2 \cdot 1 - a^2};$$

and this is the reduced generating function which tells us, by its denominator factors, that the complete system of the quadratic is composed of the form itself of degree order 1, 2 shown by az^2 , and of the Hessian of degree order 2, 0 shown by a^2 .

Again, for the cubic, we can find

$$A_3(z) = \frac{1 - a^3 z^3}{1 - az^3 \cdot 1 - a^2 z^2 \cdot 1 - a^3 z \cdot 1 - a^4},$$

where the ground forms are indicated by the denominator factors, viz.: these are the cubic itself of degree order 1, 3; the Hessian of degree order 2, 2; the cubi-covariant G of degree order 3, 3, and the quartic invariant of degree order 4, 0. Further, the numerator factor establishes that these are not all algebraically independent, but are connected by a syzygy of degree order 6, 6.

Similarly for the quartic

$$A_4(z) = \frac{1 - a^4 z^{12}}{1 - az^4 \cdot 1 - a^2 \cdot 1 - a^3 z^4 \cdot 1 - a^3 \cdot 1 - a^3 z^3},$$

establishing the 5 ground forms and the syzygy which connects them.

The process is not applicable with complete success to quintic and higher ordered binary forms. This arises from the circumstance that the simple syzygies between the ground forms are not all independent, but are connected by second syzygies, and these again by third syzygies, and so on; this introduces new difficulties which have not been completely overcome. As regards invariants a little further progress has been made by Cayley, who established the two generating functions for the quintic

$$\frac{1 - a^{36}}{1 - a^4 \cdot 1 - a^3 \cdot 1 - a^{12} \cdot 1 - a^{16}},$$

and for the sextic

$$\frac{1 - a^{80}}{1 - a^2 \cdot 1 - a^4 \cdot 1 - a^3 \cdot 1 - a^{10} \cdot 1 - a^{13}}.$$

Accounts of further attempts in this direction will be found in Cayley's *Memoirs on Quantics* (Collected Papers), in the papers of Sylvester and Franklin (*Amer. J. i. iv.*), and in Elliott's *Algebra of Quantics*, chap. viii.

Perpetuants.—Many difficulties, connected with binary forms of finite order, disappear altogether when we come to consider the form of infinite order. In this case the ground forms, called also perpetuants, have been enumerated and actual representative

seminvariant forms established. Putting n equal to ∞ , in a generating function obtained above, we find that the function, which enumerates the aszygetic seminvariants of degree θ , is

$$\frac{1}{1 - z^2 \cdot 1 - z^3 \cdot 1 - z^4 \dots 1 - z^\theta}$$

that is to say, of the weight w , we have one form corresponding to each non-unitary partition of w into the parts 2, 3, 4, ... θ . The extraordinary advantage of the transformation of Ω to association with non-unitary symmetric functions is now apparent; for we may take, as representative forms, the symmetric functions which are symbolically denoted by the partitions referred to. *Ex. gr.*, of degrees 3 weight 8, we have the two forms $(3^2 2)$, $\alpha(2^4)$. If we wish merely to enumerate those whose partitions contain the figure θ , and do not therefore contain any power of α as a factor, we have the generator

$$\frac{z^\theta}{1 - z^2 \cdot 1 - z^3 \cdot 1 - z^4 \dots 1 - z^\theta}$$

If $\theta=2$, every form is obviously a ground form or perpetuant, and the series of forms is denoted by (2) , (2^2) , (2^3) , ... (2^{k+1}) ... Similarly, if $\theta=3$, every form $(3^{k+1} 2^\lambda)$ is a perpetuant. For these two cases the perpetuants are enumerated by

$$\frac{z^2}{1 - z^2} \text{ and } \frac{z^3}{1 - z^2 \cdot 1 - z^3}$$

respectively.

When $\theta=4$ it is clear that no form, whose partition contains a part 3, can be reduced; but every form, whose partition is composed of the parts 4 and 2, is by elementary algebra reducible by means of perpetuants of degree 2. These latter forms are enumerated by $\frac{z^4}{1 - z^2 \cdot 1 - z^4}$; hence the generator of quartic perpetuants must be

$$\frac{z^4}{1 - z^2 \cdot 1 - z^3 \cdot 1 - z^4} - \frac{z^4}{1 - z^2 \cdot 1 - z^4} = \frac{z^7}{1 - z^2 \cdot 1 - z^3 \cdot 1 - z^4}$$

and the general form of perpetuant is $(4^{k+1} 3^\lambda + 12^\mu)$.

When $\theta \geq 5$, the reducible forms are connected by syzygies which there is some difficulty in enumerating. Sylvester, Cayley, and MacMahon succeeded, by a laborious process, in establishing the generators for $\theta=5$, and $\theta=6$, viz.:

$$\frac{z^{15}}{1 - z^2 \cdot 1 - z^3 \cdot 1 - z^4 \cdot 1 - z^5} \text{ , } \frac{z^{24}}{1 - z^2 \cdot 1 - z^3 \cdot 1 - z^4 \cdot 1 - z^5 \cdot 1 - z^6}$$

but the true method of procedure is that of Stroh which we are about to explain.

Method of Stroh.—In the section on "Symmetric Functions," it was noted that Stroh considers

$$(\sigma_1 a_1 + \sigma_2 a_2 + \dots + \sigma_\theta a_\theta)^w,$$

where $\sigma_1 + \sigma_2 + \dots + \sigma_\theta = 0$ and $\frac{a_1^s}{s!} - \frac{a_2^s}{s!} = \dots = \frac{a_\theta^s}{s!} = a_s$, symbolically, to be the fundamental form of seminvariant of degree θ and weight w ; he observes that every form of this degree and weight is a linear function of such symbolic expressions. We may write

$$(1 + \sigma_1 \xi)(1 + \sigma_2 \xi) \dots (1 + \sigma_\theta \xi) = 1 + A_2 \xi^2 + A_3 \xi^3 + \dots + A_\theta \xi^\theta.$$

If we expand the symbolic expression by the multinomial theorem, and remember that any symbolic product $a_1^{\pi_1} a_2^{\pi_2} a_3^{\pi_3} \dots$ retains the same value, however the suffixes be permuted, we shall obtain a sum of terms, such as $w! \frac{a_1^{\pi_1} a_2^{\pi_2} a_3^{\pi_3} \dots}{\pi_1! \pi_2! \pi_3! \dots} \sum \sigma_1^{\pi_1} \sigma_2^{\pi_2} \sigma_3^{\pi_3} \dots$, which in real form is $w! a_{\pi_1} a_{\pi_2} a_{\pi_3} \dots \sum \sigma_1^{\pi_1} \sigma_2^{\pi_2} \sigma_3^{\pi_3} \dots$; and, if we express $\sum \sigma_1^{\pi_1} \sigma_2^{\pi_2} \sigma_3^{\pi_3} \dots$ in terms of A_2, A_3, \dots and arrange the whole as a linear function of products of A_2, A_3, \dots , each coefficient will be a seminvariant, and the aggregate of the coefficients will give us the complete aszygetic system of the given degree and weight. When the proper degree θ is $< w$ a factor $a_0^{w-\theta}$ must be of course understood.

Ex. gr.

$$\frac{1}{2!}(\sigma_1 a_1 + \sigma_2 a_2 + \sigma_3 a_3 + \sigma_4 a_4)^2 = \frac{a_1^2}{2!} \sum \sigma_1^2 + a_1 a_2 \sum \sigma_1 \sigma_2$$

$$= a_2(-2A_2) + a_2^2 A_2 = (a_1^2 - 2a_2) A_2 = (2) A_2 \equiv a_2^2 (2) A_2.$$

In general the coefficient, of any product $A_{\pi_1} A_{\pi_2} A_{\pi_3} \dots$, will have, as coefficient, a seminvariant which, when expressed by partitions, will have as leading partition (preceding in dictionary order all others) the partition $(\pi_1 \pi_2 \pi_3 \dots)$. Now the symbolic expression of the seminvariant can be expanded by the binomial theorem so as to be exhibited as a sum of products of seminvariants,

of lower degree if $\sigma_1 a_1 + \sigma_2 a_2 + \dots + \sigma_\theta a_\theta$ can be broken up into any two portions

$$(\sigma_1 a_1 + \sigma_2 a_2 + \dots + \sigma_s a_s) + (\sigma_{s+1} a_{s+1} + \sigma_{s+2} a_{s+2} + \dots + \sigma_\theta a_\theta),$$

such that $\sigma_1 + \sigma_2 + \dots + \sigma_s = 0$, for then

$$\sigma_{s+1} + \sigma_{s+2} + \dots + \sigma_\theta = 0;$$

and each portion raised to any power denotes a seminvariant.

Stroh assumes that every reducible seminvariant can in this way be reduced. The existence of such a relation, as $\sigma_1 + \sigma_2 + \dots + \sigma_s = 0$, necessitates the vanishing of a certain function of the coefficients $A_2, A_3, \dots, A_\theta$, and as a consequence one product of these coefficients can be eliminated from the expanded form and no seminvariant, which appears as a coefficient to such a product (which may be the whole or only a part of the complete product with which the seminvariant is associated), will be capable of reduction.

Ex. gr. for $\theta=2$, $(\sigma_1 a_1 + \sigma_2 a_2)^w$; either σ_1 or σ_2 will vanish if $\sigma_1 \sigma_2 = A_2 = 0$; but every term, in the development, is of the form $(22 \dots) A_2^{\frac{1}{2} w}$ and therefore vanishes; so that none are left to undergo reduction. Therefore every form of degree 2, except of course that one whose weight is zero, is a perpetuant. The

generating function is $\frac{z^2}{1 - z^2}$.

For $\theta=3$, $(\sigma_1 a_1 + \sigma_2 a_2 + \sigma_3 a_3)^w$; the condition is clearly $\sigma_1 \sigma_2 \sigma_3 = A_3 = 0$, and since every seminvariant, of proper degree 3, is associated, as coefficient, with a product containing A_3 , all such are perpetuants. The general form is $(3^k 2^\lambda)$ and the generating function $\frac{z^3}{1 - z^2 \cdot 1 - z^3}$.

For $\theta=4$, $(\sigma_1 a_1 + \sigma_2 a_2 + \sigma_3 a_3 + \sigma_4 a_4)^w$; the condition is

$$\sigma_1 \sigma_2 \sigma_3 \sigma_4 (\sigma_1 + \sigma_2)(\sigma_1 + \sigma_3)(\sigma_1 + \sigma_4) = A_4 A_3 = 0.$$

Hence every product of A_1, A_2, A_3, A_4 , which contains the product $A_4 A_3$ disappears before reduction; this means that every seminvariant, whose partition contains the parts 4, 3, is a perpetuant. The general form of perpetuant is $(4^k 3^\lambda 2^\mu)$ and the generating function

$$\frac{z^7}{1 - z^2 \cdot 1 - z^3 \cdot 1 - z^4}$$

In general when θ is even and $= 2\phi$, the condition is

$$\sigma_1 \sigma_2 \dots \sigma_{2\phi} \Pi(\sigma_1 + \sigma_2) \Pi(\sigma_1 + \sigma_2 + \sigma_3) \dots \Pi(\sigma_1 + \sigma_2 + \dots + \sigma_\phi) = 0;$$

and we can determine the lowest weight of a perpetuant; the degree in the quantities σ is

$$2\phi + \binom{2\phi}{2} + \binom{2\phi}{3} + \dots + \frac{1}{2} \binom{2\phi}{\phi} = 2^{2\phi-1} - 1 = 2^{\theta-1} - 1.$$

Again, if θ is uneven $= 2\phi + 1$, the condition is

$$\sigma_1 \sigma_2 \dots \sigma_{2\phi+1} \Pi(\sigma_1 + \sigma_2) \Pi(\sigma_1 + \sigma_2 + \sigma_3) \dots \Pi(\sigma_1 + \sigma_2 + \dots + \sigma_\phi) = 0;$$

and the degree, in the quantities σ , is

$$2\phi + 1 + \binom{2\phi+1}{2} + \binom{2\phi+1}{3} + \dots + \binom{2\phi+1}{\phi} = 2^{2\phi} - 1 = 2^{\theta-1} - 1.$$

Hence the lowest weight of a perpetuant is $2^{\theta-1} - 1$, when θ is > 2 . The generating function is thus

$$\frac{z^{2^{\theta-1}-1}}{(1 - z^2)(1 - z^3)(1 - z^4) \dots (1 - z^\theta)}$$

The actual form of a perpetuant of degree θ has been shown by MacMahon to be

$$(\theta^{\kappa_\theta+1} \frac{1}{\theta-1} \kappa_{\theta-1} + 1 \frac{1}{\theta-2} \kappa_{\theta-2} + 2 \frac{1}{\theta-3} \kappa_{\theta-3} + 4 \dots 3^{\kappa_3+2^{\theta-4}} 2^{\kappa_2}),$$

$\kappa_\theta, \kappa_{\theta-1}, \dots, \kappa_2$ being given any zero or positive integer values.

Simultaneous Seminvariants of two Binary Forms.—Taking the two forms to be

$$a_0 x^p + p a_1 x^{p-1} x_2 + p(p-1) a_2 x^{p-2} x_2^2 + \dots + a_p x_2^p,$$

$$b_0 x^q + q b_1 x^{q-1} x_2 + q(q-1) b_2 x^{q-2} x_2^2 + \dots + b_q x_2^q,$$

every leading coefficient of a simultaneous covariant vanishes by the operation of

$$\Omega_a + \Omega_b = a_0 \frac{d}{da_1} + a_1 \frac{d}{da_2} + \dots + a_{p-1} \frac{d}{da_p} + b_0 \frac{d}{db_1} + b_1 \frac{d}{db_2} + \dots + b_{q-1} \frac{d}{db_q}.$$

Observe that we may employ the principle of suffix diminution to obtain from any seminvariant one appertaining to a $p-1^{\text{ic}}$ and a $q-1^{\text{ic}}$, and that suffix augmentation produces a portion of a higher seminvariant, the degree in each case remaining unaltered. Remark, too, that we are in association with non-unitary symmetric functions of two systems of quantities which will be

denoted by partitions in brackets $()_a, ()_b$ respectively. Solving the equation

$$(\Omega_a + \Omega_b)u = 0,$$

by the ordinary theory of linear partial differential equations, we obtain $p+q+1$ independent solutions, of which p appertain to $\Omega_a u = 0, q$ to $\Omega_b u = 0$; the remaining one is $J_{ab} = a_0 b_1 - a_1 b_0$, the leading coefficient of the Jacobian of the two forms. This constitutes an algebraically complete system, and, in terms of its members, all seminvariants can be rationally expressed. A similar theorem holds in the case of any number of binary forms, the mixed seminvariants being derived from the Jacobians of the several pairs of forms. If the seminvariant be of degrees θ, θ' in the coefficients, the forms of orders p, q respectively, and the weight w , the degree of the covariant in the variables will be $p\theta + q\theta' - 2w = \epsilon$, an easy generalization of the theorem connected with a single form.

The general term of a seminvariant of degrees θ, θ' and weight w will be

$$a_0^{\rho_0} a_1^{\rho_1} a_2^{\rho_2} \dots a_p^{\rho_p} b_0^{\sigma_0} b_1^{\sigma_1} b_2^{\sigma_2} \dots b_q^{\sigma_q}$$

where $\sum_1^p \rho_i = \theta, \sum_1^q \sigma_i = \theta'$ and $\sum_1^p \rho_i + \sum_1^q \sigma_i = w$.

The number of such terms is the number of partitions of w into $\theta + \theta'$ parts, the part magnitudes, in the two portions, being limited not to exceed p and q respectively. Denote this number by $(w; \theta, p; \theta', q)$. The number of linearly independent seminvariants of the given type will then be denoted by

$$(w; \theta, p; \theta', q) - (w-1; \theta, p; \theta', q);$$

and will be given by the coefficient of $a^\theta b^{\theta'} z^w$ in

$$\frac{1-z}{1-a.1-az.1-az^2 \dots 1-az^p.1-b.1-bz.1-bz^2 \dots 1-bz^q};$$

that is, by the coefficient of z^w in

$$\frac{1-z^{p+1}.1-z^{p+2} \dots 1-z^{p+1}.1-z^{p+2} \dots 1-z^{p+1}}{1-z.1-z^2.1-z^3 \dots 1-z^p.1-z^{p+1}.1-z^{p+2} \dots 1-z^p};$$

which preserves its expression when θ and p and θ' and q are separately or simultaneously interchanged.

Taking the first generating function, and writing $az^p, bz^q, \frac{1}{z^2}$ for a, b , and z respectively, we obtain the coefficient of $a^\theta b^{\theta'} z^{p\theta + q\theta' - 2w}$, that is of $a^\theta b^{\theta'} z^\epsilon$, in

$$\frac{1-az^p.1-az^{p+2} \dots 1-az^{p+2}.1-az^{p+1}.1-bz^q.1-bz^{q+2} \dots 1-bz^{q+2}.1-bz^{q+1}}{1-z.1-z^2.1-z^3 \dots 1-z^p.1-z^{p+1}.1-z^{p+2} \dots 1-z^p};$$

the unreduced generating function which enumerates the covariants of degrees θ, θ' in the coefficients and order ϵ in the variables. Thus, for two linear forms, $p=q=1$, we find

$$\frac{1-z^{-2}}{1-az.1-az^{-1}.1-bz.1-bz^{-1}}$$

the positive part of which is

$$\frac{1}{1-az.1-bz.1-ab};$$

establishing the ground forms of degrees-order $(1, 0; 1), (0, 1; 1), (1, 1; 0)$, viz. :—the linear forms themselves and their Jacobian J_{ab} . Similarly, for a linear and a quadratic, $p=1, q=2$, and the reduced form is found to be

$$\frac{1-a^2 b^2 z^2}{1-az.1-bz^2.1-abz.1-b^2.1-a^2 b};$$

where the denominator factors indicate the forms themselves, their Jacobian, the invariant of the quadratic and their resultant; connected, as shown by the numerator, by a syzygy of degrees-order $(2, 2; 2)$.

The complete theory of the perpetuants appertaining to two or more forms of infinite order has not yet been established. For two forms the seminvariants of degrees $1, 1$ are enumerated by

$\frac{1}{1-z^2}$, and the only one which is reducible is $a_0 b_0$ of weight zero; hence the perpetuants of degrees $1, 1$ are enumerated by

$$\frac{1}{1-z} - 1 = \frac{z}{1-z};$$

and the series is evidently

$$a_0 b_1 - a_1 b_0, \\ a_0 b_2 - a_1 b_1 + a_2 b_0, \\ a_0 b_3 - a_1 b_2 + a_2 b_1 - a_3 b_0,$$

one for each of the weights $1, 2, 3, \dots$ *ad infin.*

For the degrees $1, 2$, the aszygetic forms are enumerated by

$\frac{1}{1-z.1-z^2}$, and the actual forms for the first three weights are

$$a_0 b_0^2, \\ (a_0 b_1 - a_1 b_0) b_0, \\ (a_0 b_2 - a_1 b_1 + a_2 b_0) b_0, \\ a_0 (b_1^2 - 2b_0 b_2), \\ (a_0 b_3 - a_1 b_2 + a_2 b_1 - a_3 b_0) b_0, \\ a_0 (b_1 b_2 - 3b_0 b_3) - a_1 (b_1^2 - 2b_0 b_2);$$

amongst these forms are included all the aszygetic forms of degrees $1, 1$, multiplied by b_0 , and also all the perpetuants of the second binary form multiplied by a_0 ; hence we have to subtract from the generating function $\frac{1}{1-z}$ and $\frac{z^2}{1-z^2}$ and we obtain the generating function of perpetuants of degrees $1, 2$

$$\frac{1}{1-z.1-z^2} - \frac{1}{1-z} - \frac{z^2}{1-z^2} = \frac{z^3}{1-z.1-z^2}.$$

The first perpetuant is the last seminvariant written, viz. :—

$$a_0 (b_0 b_2 - 3b_0 b_3) - a_1 (b_1^2 - 2b_0 b_2),$$

or, in partition notation,

$$a_0(21)_b - (1)_a(2)_b;$$

and, in this form, it is at once seen to satisfy the partial differential equation. It is important to notice that the expression

$$(\theta)_a (\theta' 1^\epsilon)_b - (\theta 1)_a (\theta' 1^{\epsilon-1})_b + (\theta 1^2)_a (\theta' 1^{\epsilon-2})_b - \dots \pm (\theta 1^\epsilon)_a (\theta')_b$$

denotes a seminvariant, if θ, θ' be neither of them unity, for, after operation, the terms destroy one another in pairs; when $\theta=0, (\theta)_a$ must be taken to denote a_0 and so for θ' . In general it is a seminvariant of degrees θ, θ' , and weight $\theta + \theta' + \epsilon$; to this there is an exception, viz., when $\theta=0$, or when $\theta'=0$, the corresponding partial degrees are 1 and 1 . When $\theta=\theta'=0$, we have the general perpetuant of degrees $1, 1$. There is a still more general form of seminvariant; we may have instead of θ, θ' any collections of non-unitary integers not exceeding θ, θ' in magnitude respectively. *Ex. gr.*

$$(2^{\lambda_2} 3^{\lambda_3} \dots \theta^{\lambda_\theta})_a (1^{\mu_2} 2^{\mu_3} \mu_3 \dots \theta^{\mu_\theta})_b \\ - (12^{\lambda_2} 3^{\lambda_3} \dots \theta^{\lambda_\theta})_a (1^{\epsilon-1} 2^{\mu_2} \mu_3 \dots \theta^{\mu_\theta})_b \\ + (1^2 2^{\lambda_2} 3^{\lambda_3} \dots \theta^{\lambda_\theta})_a (1^{\epsilon-2} 2^{\mu_2} \mu_3 \dots \theta^{\mu_\theta})_b \\ \dots \\ (-)^{\epsilon} (1^{\epsilon_2} 2^{\lambda_2} 3^{\lambda_3} \dots \theta^{\lambda_\theta})_a (2^{\mu_2} 3^{\mu_3} \dots \theta^{\mu_\theta})_b,$$

is a seminvariant; and since these forms are clearly enumerated by

$$\frac{1}{1-z.1-z^2 \dots 1-z^\theta.1-z^2.1-z^3 \dots 1-z^{\theta'}},$$

an expression which also enumerates the aszygetic seminvariants, we may regard the form, written, as denoting the general form of aszygetic seminvariant; a very important conclusion. For the case in hand, from the simplest perpetuant of degrees $1, 2$, we derive the perpetuants of weight w ,

$$a_0(21^{w-2})_b - a_1(21^{w-3})_b + a_2(21^{w-4})_b - \dots \pm a_{w-2}(2)_b, \\ a_0(2^2 1^{w-4})_b - a_1(2^2 1^{w-5})_b + a_2(2^2 1^{w-6})_b - \dots \pm a_{w-4}(2^2)_b, \\ a_0(2^3 1^{w-6})_b - a_1(2^3 1^{w-7})_b + a_2(2^3 1^{w-8})_b - \dots \pm a_{w-6}(2^3)_b,$$

a series of $\frac{1}{2}(w-2)$ or of $\frac{1}{2}(w-1)$ forms according as w is even or uneven. Their number for any weight w is the number of ways of composing $w-3$ with the parts $1, 2$, and thus the generating function is verified. We cannot, by this method, easily discuss the perpetuants of degrees $2, 2$, because a syzygy presents itself as early as weight 2 . It is better now to proceed by the method of Stroh.

We have the symbolic expression of a seminvariant,

$$\frac{1}{w!} (\sigma_1 \alpha_1 + \sigma_2 \alpha_2 + \dots + \sigma_\theta \alpha_\theta + \tau_1 \beta_1 + \tau_2 \beta_2 + \dots + \tau_{\theta'} \beta_{\theta'})^w$$

where

$$\frac{\alpha_i^s}{s!} = \frac{\alpha_i^s}{s!} = \dots = \alpha_i; \quad \frac{\beta_i^s}{s!} = \frac{\beta_i^s}{s!} = \dots = \beta_i;$$

and

$$\sigma_1 + \sigma_2 + \dots + \sigma_\theta + \tau_1 + \tau_2 + \dots + \tau_{\theta'} = 0.$$

Proceeding as we did in the case of the single binary form we find that for a given total degree $\theta + \theta'$, the condition which expresses reducibility is of total degree $2^{\theta+\theta'-1} - 1$ in the coefficients σ and τ ; combining this with the knowledge of the generating function of aszygetic forms of degrees θ, θ' , we find that the perpetuants of these degrees are enumerated by

$$\frac{z^{\theta+\theta'-1} - 1}{1-z.1-z^2.1-z^3 \dots 1-z^\theta.1-z^2.1-z^3 \dots 1-z^{\theta'}},$$

and this is true for $\theta + \theta' = 2$ as well as for other values of $\theta + \theta'$ (compare the case of the single binary form).

dition $\sigma_1\tau_1\nu_1 = A_1B_1C_1 = 0$, where $A_1 + B_1 + C_1 = 0$. We have a choice of six products for our base, viz.,

$$B_1^2C_1, B_1C_1^2, A_1^2C_1, A_1C_1^2, A_1^2B_1, A_1B_1^2,$$

and these yield respectively

$$\begin{aligned} & | \alpha_0(1^2)_b(1)_c |, | \alpha_0(1)_b(1^2)_c |, \\ & | (1^2)_a b_0(1)_c |, | (1)_a b_0(1^2)_c |, \\ & | (1^2)_a(1)_b c_0 |, | (1)_a(1^2)_b c_0 |, \end{aligned}$$

Taking the product $A_1^2B_1$ and the corresponding form

$$| (1^2)_a(1)_b c_0 |$$

we find

$$\begin{aligned} & | (1^2)_a(1)_b | c_0 - | (1)_a(1)_b | c_1 + | \alpha_0(1)_b | c_2 \\ & = (a_2b_1 - 3a_2b_0)c_0 - (a_1b_1 - 2a_2b_0)c_1 + (a_0b_1 - a_1b_0)c_2, \end{aligned}$$

the simplest perpetuant of the kind; the general form, given by the generator $\frac{z^3}{(1-z)^2}$, being

$$| (1^{k_1+2})_a(1^{\lambda_1+1})_b c_0 |.$$

Similarly for 4 binary forms the simplest perpetuant, of degrees 1, 1, 1, 1, is (corresponding to product $A_1^4B_1^2C_1$)

$$| (1^4)_a(1^2)_b(1)_c d_0 |;$$

and has the expression

$$\begin{aligned} & a_0(b_2c_1d_4 - 3b_3c_0d_4) \\ & + a_1(b_1c_1d_4 + 2b_2c_0d_4 - b_2c_1d_3 + 3b_3c_0d_3) \\ & + a_2(b_0c_1d_4 - b_1c_0d_4 + 2b_1c_1d_3 - 4b_2c_0d_3 + b_2c_1d_2 - 3b_3c_0d_2) \\ & + a_3(-3b_0c_1d_3 + 3b_1c_0d_3 - 3b_1c_1d_2 + 6b_2c_0d_2 - b_2c_1d_1 + 3b_3c_0d_1) \\ & + a_4(6b_0c_1d_2 - 6b_1c_0d_2 + 4b_1c_1d_1 - 8b_2c_0d_1 + b_2c_1d_0 - 3b_3c_0d_0) \\ & + a_5(-10b_0c_1d_1 + 10b_1c_0d_1 - 5b_1c_1d_0 + 10b_2c_0d_0) \\ & + a_6(15b_0c_1d_0 - 15b_1c_0d_0). \end{aligned}$$

V. RESTRICTED SUBSTITUTIONS.

We may regard the factors of a binary n^{ic} equated to zero as denoting n straight lines through the origin, the co-ordinates being Cartesian and the axes inclined at any angle. Taking the variables to be x, y and affecting the linear transformation

$$\begin{aligned} x &= \lambda_1 X + \mu_1 Y, \\ y &= \lambda_2 X + \mu_2 Y, \end{aligned}$$

so that

$$\frac{y}{x} = \frac{\lambda_2 + \mu_2 \frac{Y}{X}}{\lambda_1 + \mu_1 \frac{Y}{X}}, \quad \frac{Y}{X} = \frac{\lambda_1 \frac{y}{x} - \lambda_2}{\mu_2 - \mu_1 \frac{y}{x}};$$

it is seen that the two lines, on which lie $(x, y), (X, Y)$, have a definite projective correspondence. The linear transformation replaces points on lines through the origin by corresponding points on projectively corresponding lines through the origin; it therefore replaces a pencil of lines by another pencil, which corresponds projectively, and harmonic and other properties of pencils which are unaltered by linear transformation we may expect to find indicated in the invariant system. Or, instead of looking upon a linear substitution as replacing a pencil of lines by a projectively corresponding pencil retaining the same axes of co-ordinates, we may look upon the substitution as changing the axes of co-ordinates retaining the same pencil. Then a binary n^{ic} , equated to zero, represents n straight lines through the origin, and the x, y , of any line through the origin are given constant multiples of the sines of the angles which that line makes with two fixed lines, the axes of co-ordinates. As new axes of co-ordinates we may take any other pair of lines through the origin, and for the X, Y corresponding to x, y any new constant multiples of the sines of the angles which the line makes with the new axes. The substitution for x, y in terms of X, Y is the most general linear substitution in virtue of the four degrees of arbitrariness introduced, viz., two by the choice of axes, two by the choice of multiples. If now the n^{ic} denote a given pencil of lines, an invariant is the criterion of the pencil possessing some particular property which is independent alike of the axes and of the multiples, and a covariant expresses that the pencil of lines which it denotes is a fixed pencil whatever be the axes or the multiples.

Besides the invariants and covariants, hitherto studied, there are others which appertain to particular cases of the general linear substitution. Thus, what have been called, seminvariants are not all of them invariants for the general substitution, but are invariants for the particular substitution

$$\begin{aligned} x_1 &= \lambda_1 \xi_1 + \mu_1 \xi_2, \\ x_2 &= \mu_2 \xi_2. \end{aligned}$$

Again, in plane geometry, the most general equations of substitution which change from old axes inclined at ω to new axes inclined at $\omega' = \beta - \alpha$, and inclined at angles α, β to the old axis of x , without change of origin, are

$$\begin{aligned} x &= \frac{\sin(\omega - \alpha)}{\sin \omega} X + \frac{\sin(\omega - \beta)}{\sin \omega} Y, \\ y &= \frac{\sin \alpha}{\sin \omega} X + \frac{\sin \beta}{\sin \omega} Y, \end{aligned}$$

a transformation of modulus

$$\frac{\sin \omega'}{\sin \omega}.$$

The theory of invariants originated in the discussion, by Boole, of this system so important in geometry. Of the quadratic

$$ax^2 + 2bxy + cy^2,$$

he discovered the two invariants

$$ac - b^2, a - 2b \cos \omega + c,$$

and it may be verified that, if the transformed of the quadratic be

$$AX^2 + 2BXY + CY^2,$$

$$AC - B^2 = \left(\frac{\sin \omega'}{\sin \omega} \right)^2 (ac - b^2),$$

$$A - 2B \cos \omega' + C = \left(\frac{\sin \omega'}{\sin \omega} \right)^2 (a - 2b \cos \omega + c).$$

The fundamental fact that he discovered was the invariance of $x^2 + 2 \cos \omega xy + y^2$, viz. —

$$x^2 + 2 \cos \omega xy + y^2 = X^2 + 2 \cos \omega' XY + Y^2,$$

from which it appears that the Boolean invariants of $ax^2 + 2bxy + cy^2$ are nothing more than the full invariants of the simultaneous quadratics

$$ax^2 + 2bxy + cy^2, x^2 + 2 \cos \omega xy + y^2,$$

the word invariant including here covariant. In general the Boolean system, of the general n^{ic} , is coincident with the simultaneous system of the n^{ic} and the quadratic $x^2 + 2 \cos \omega xy + y^2$.

Orthogonal System.—In particular, if we consider the transformation from one pair of rectangular axes to another pair of rectangular axes we obtain an orthogonal system which we will now briefly inquire into. We have $\cos \omega' = \cos \omega = 0$ and the substitution

$$\begin{aligned} x_1 &= \cos \theta X_1 - \sin \theta X_2, \\ x_2 &= \sin \theta X_1 + \cos \theta X_2, \end{aligned}$$

with modulus unity. This is called the *direct* orthogonal substitution, because the sense of rotation from the axis of X_1 to the axis of X_2 is the same as that from that of x_1 to that of x_2 . If the senses of rotation be opposite we have the skew orthogonal substitution

$$\begin{aligned} x_1 &= \cos \theta X_1 + \sin \theta X_2, \\ x_2 &= \sin \theta X_1 - \cos \theta X_2, \end{aligned}$$

of modulus -1 . In both cases $\frac{d}{dx_1}$ and $\frac{d}{dx_2}$ are cogredient with x_1 and x_2 ; for, in the case of direct substitution,

$$\begin{aligned} \frac{d}{dx_1} &= \cos \theta \frac{d}{dX_1} - \sin \theta \frac{d}{dX_2}, \\ \frac{d}{dx_2} &= \sin \theta \frac{d}{dX_1} + \cos \theta \frac{d}{dX_2}; \end{aligned}$$

and for skew substitution

$$\begin{aligned} \frac{d}{dx_1} &= \cos \theta \frac{d}{dX_1} + \sin \theta \frac{d}{dX_2}, \\ \frac{d}{dx_2} &= \sin \theta \frac{d}{dX_1} - \cos \theta \frac{d}{dX_2}. \end{aligned}$$

Hence, in both cases, contragredency and cogredency are identical, and contravariants are included in covariants.

Consider the binary n^{ic} , $(a_1x_1 + a_2x_2)^n = a_x^2$, and the direct substitution

$$\begin{aligned} x_1 &= \lambda X_1 - \mu X_2, \\ x_2 &= \mu X_1 + \lambda X_2, \end{aligned}$$

where $\lambda^2 + \mu^2 = 1$; λ, μ replacing $\cos \theta, \sin \theta$ respectively. In the notation

$$a_x = a_1x_1 + a_2x_2,$$

observe that

$$\begin{aligned} a_x &= a_1^2 + a_2^2, \\ a_b &= a_1b_1 + a_2b_2. \end{aligned}$$

Suppose that

$$a_x = b_x = c_x = \dots$$

is transformed into

$$A_x = B_x = C_x = \dots$$

then of course $(AB) = (ab)$ the fundamental fact which appertains to the theory of the general linear substitution; now here we have additional and equally fundamental facts; for since

$$\begin{aligned} A_1 &= \lambda a_1 + \mu a_2, A_2 = -\mu a_1 + \lambda a_2, \\ A_A &= A_1^2 + A_2^2 = (\lambda^2 + \mu^2)(a_1^2 + a_2^2) = a_a; \\ A_B &= A_1B_1 + A_2B_2 = (\lambda^2 + \mu^2)(a_1b_1 + a_2b_2) = a_b; \\ (XA) &= X_1A_2 - X_2A_1 = (\lambda x_1 + \mu x_2)(-\mu a_1 + \lambda a_2) \\ &\quad - (-\mu x_1 + \lambda x_2)(\lambda a_1 + \mu a_2) = (\lambda^2 + \mu^2)(x_1a_2 - x_2a_1) = (xa); \end{aligned}$$

showing that, in the present theory, $a_a, a_b,$ and (ax) possess the invariant property. Since $x_1^2 + x_2^2 = x_x$ we have six types of symbolic factors which may be used to form invariants and covariants, viz.—

$$(ab), a_a, a_b, (ax), a_x, x_x.$$

The general form of covariant is therefore

$$\begin{aligned} & (ab)^{h_1}(ac)^{h_2}(bc)^{h_3} \dots a_a^{i_1} b_b^{i_2} c_c^{i_3} \dots a_x^{j_1} a_x^{j_2} b_x^{j_3} \dots \\ & \times (ax)^{k_1}(ab)^{k_2}(ac)^{k_3} \dots a_x^{l_1} b_x^{l_2} c_x^{l_3} \dots x_x^m \\ & = (\Delta B)^{h_1}(\Delta C)^{h_2}(\Delta C)^{h_3} \dots A_A^{i_1} B_B^{i_2} C_C^{i_3} \dots A_B^{j_1} A_C^{j_2} B_C^{j_3} \dots \\ & \times (XA)^{k_1}(XB)^{k_2}(XC)^{k_3} \dots A_X^{l_1} B_X^{l_2} C_X^{l_3} \dots X_X^m. \end{aligned}$$

If this be of order ϵ and appertain to an n^{ic}

$$\begin{aligned} \Sigma k + \Sigma l + 2m &= \epsilon, \\ h_1 + h_2 + \dots + 2i_1 + j_1 + j_2 + \dots + k_1 + l_1 &= n, \\ h_1 + h_3 + \dots + 2i_2 + j_1 + j_3 + \dots + k_2 + l_2 &= n, \\ h_2 + h_3 + \dots + 2i_3 + j_2 + j_3 + \dots + k_3 + l_3 &= n; \end{aligned}$$

viz., the symbols a, b, c, \dots must each occur n times. It may denote a simultaneous orthogonal invariant of forms of orders n_1, n_2, n_3, \dots ; the symbols must then present themselves n_1, n_2, n_3, \dots times respectively. The number of different symbols a, b, c, \dots denotes the degree θ of the covariant in the coefficients. The coefficients of the covariants are homogeneous, but not in general isobaric functions, of the coefficients of the original form or forms. Of the above general form of covariant there are important transformations due to the symbolic identities:—

$$(ab)^2 = a_a b_b - a_b^2; \quad (ax)^2 = a_a x_x - a_x^2;$$

as a consequence any even power of a determinant factor may be expressed in terms of the other symbolic factors, and any uneven power may be expressed as the product of its first power and a function of the other symbolic factors. Hence in the above general form of covariant we may suppose the exponents

$$h_1, h_2, h_3, \dots, k_1, k_2, k_3, \dots$$

if the determinant factors to be, each of them, either zero or unity. Or, if we please, we may leave the determinant factors untouched and consider the exponents $j_1, j_2, j_3, \dots, l_1, l_2, l_3, \dots$ to be, each of them, either zero or unity. Or, lastly, we may leave the exponents h, k, j, l untouched and consider the product

$$a_a^{i_1} b_b^{i_2} c_c^{i_3} \dots x_x^m,$$

to be reduced either to the form g_g^i where g is a symbol of the series a, b, c, \dots or to a power of x_x . To assist us in handling the symbolic products we have not only the identity

$$(ab)c_x + (bc)a_x + (ca)b_x = 0,$$

but also

$$\begin{aligned} (ab)x_x + (ba)a_x + (xa)b_x &= 0, \\ (ab)a_x + (bc)a_a + (ca)a_b &= 0, \end{aligned}$$

and many others which may be derived from these in the manner which will be familiar to students of the works of Aronhold, Clebsch, and Gordan. Previous to continuing the general discussion it is useful to have before us the orthogonal invariants and covariants of the binary linear and quadratic forms.

For the linear forms $a_0 x_1 + a_1 x_2 = a_x = b_x$ there are four fundamental forms,

- (i.) $a_x = \bar{a}_0 x_1 + \bar{a}_1 x_2$ of degree-order $(1, 1)$,
- (ii.) $x_x = x_1^2 + x_2^2$,, $(0, 2)$,
- (iii.) $(ax) = \bar{a}_1 x_1 - \bar{a}_0 x_2$,, $(1, 1)$,
- (iv.) $a_b = \bar{a}_0^2 + \bar{a}_1^2$,, $(2, 0)$,

(iii.) and (iv.) being the linear covariant and the quadrinvariant respectively. Every other concomitant is a rational integral function of these four forms. The linear covariant, obviously the Jacobian of a_x and x_x , is the line perpendicular to a_x , and the vanishing of the quadrinvariant a_b is the condition that a_x passes through one of the circular points at infinity. In general any pencil of lines, connected with the line a_x by descriptive or metrical properties, has for its equation a rational integral function of the four forms equated to zero.

For the quadratic $\bar{a}_0 x_1^2 + 2\bar{a}_1 x_1 x_2 + \bar{a}_2 x_2^2$, we have

- (i.) $a_x^2 = \bar{a}_1 x_1^2 + 2\bar{a}_2 x_1 x_2 + \bar{a}_2 x_2^2$,
- (ii.) $x_x = x_1^2 + x_2^2$,
- (iii.) $(ab)^2 = 2(\bar{a}_0 \bar{a}_2 - \bar{a}_1^2)$,
- (iv.) $a_a = \bar{a}_0 + \bar{a}_2$,
- (v.) $(ax)a_x = \bar{a}_1 x_1^2 + (\bar{a}_2 - \bar{a}_0)x_1 x_2 - \bar{a}_1 x_2^2$.

This is the fundamental system; we may, if we choose, replace

$(ab)^2$ by $a_b^2 = \bar{a}_0^2 + 2\bar{a}_1^2 + \bar{a}_2^2$ since the identity $a_a b_b - a_b^2 = (ab)^2$ shows the syzygetic relation

$$(a_0 + a_2)^2 - (\bar{a}_0^2 + 2\bar{a}_1^2 + \bar{a}_2^2) = 2(\bar{a}_0 \bar{a}_2 - \bar{a}_1^2).$$

There is no linear covariant, since it is impossible to form a symbolic product which will contain x once and at the same time appertain to a quadratic. $(v.)$ is the Jacobian; geometrically it denotes the bisectors of the angles between the lines a_x^2 or, as we may say, the common harmonic conjugates of the lines a_x^2 and the lines a_x . The linear invariant a_a is such that, when equated to zero, it determines the lines a_x^2 as harmonically conjugate to the lines a_x ; or, in other words, it is the condition that a_x^2 may denote lines at right angles.

To resume the general discussion we recall the relations

$$A_1 = \lambda a_1 + \mu a_2, \quad A_2 = -\mu a_1 + \lambda a_2,$$

and put so that

$$\begin{aligned} \lambda &= \lambda_1 = \mu_2; \quad \mu = \mu_1 = -\lambda_2; \\ A_1 &= a_\lambda = (a\mu), \\ A_2 &= a_\mu = (\lambda a), \end{aligned}$$

giving

$$\begin{aligned} \bar{A}_k &= A_1^{n-k} A_2^k = a_\lambda^{n-k} a_\mu^k \\ &= (a\mu)^{n-k} a_\mu^k = a_\lambda^{n-k} (\lambda a)^k = (a\mu)^{n-k} (\lambda a)^k \\ A_x^n &= (a_\lambda X_1 + a_\mu X_2)^n = \{ (a\mu)X_1 + a_\mu X_2 \}^n \\ &= \{ a_\lambda X_1 + (\lambda a)X_2 \}^n = \{ (a\mu)X_1 + (\lambda a)X_2 \}^n; \end{aligned}$$

four forms of expression.

The polar process is available here to an enhanced degree. For put

$$f = a_x^m, \quad \phi = (ax)^n,$$

we not only have

$$f_y^k = a_x^{m-k} a_y^k,$$

but also

$$\phi_y^k = (ax)^{n-k} (ya)^k;$$

and just as the substitution of $x_1 + ty_1, x_2 + ty_2$ for x_1, x_2 converts a_x into $a_x + ta_y$, the same substitution converts (ax) into $(ax) + t(ya)$, and the symbolic power

$$\{ (ax) + t(ya) \}^n$$

may be regarded as the generator of polars of $(ax)^n$. Note also the results

$$\begin{aligned} \frac{1}{m} \left(\frac{d}{dy} \frac{d}{dx} \right) a_x^m &= a_x^{m-1} (ya), \\ \frac{1}{n} \left(\frac{d}{dx} y \right) (ax)^n &= (ax)^{n-1} a_y, \end{aligned}$$

where

$$y_1 \frac{d}{dx_1} - y_2 \frac{d}{dx_2} = \left(y \frac{d}{dx} \right) = - \left(\frac{d}{dx} y \right);$$

indicating processes analogous to the polar process by which

$$\begin{aligned} a_x^m &\text{ is converted into } a_x^{m-k} (ya)^k, \\ (ax)^n &\text{ is converted into } (ax)^{n-k} a_y^k. \end{aligned}$$

Combining the processes we find that we are in possession of a process, equivalent to a compound partial differential operation, by which a_x^m can be converted into $a_x^{m-k_1-k_2} a_y^{k_1} (ya)^{k_2}$, and one also by which $(ax)^n$ can be converted into $(ax)^{n-k_1-k_2} (ya)^{k_1} a_y^{k_2}$.

We already know that the polar $a_x^{m-k} a_y^k$ satisfies the partial differential equation of the second order

$$\frac{\partial^2 u}{\partial x_1 \partial y_2} - \frac{\partial^2 u}{\partial x_2 \partial y_1} = 0;$$

and the performance of the operation

$$\frac{1}{(m-k)k} \left(\frac{\partial^2}{\partial x_1 \partial y_2} - \frac{\partial^2}{\partial x_2 \partial y_1} \right)$$

has been termed the Ω process. As regards the new forms

$$u_1 = a_x^{m-k} (ya)^k, \quad u_2 = (ax)^{n-k} a_y^k,$$

since

$$\begin{aligned} \frac{\partial^2 u_1}{\partial x_1 \partial y_1} &= (m-k)k a_x^{m-k-1} (ya)^{k-1} a_1 a_2, \\ \frac{\partial^2 u_1}{\partial x_2 \partial y_2} &= (m-k)k a_x^{m-k-1} (ya)^{k-1} (-a_1 a_2), \\ \frac{\partial^2 u_2}{\partial x_1 \partial y_1} &= (n-k)k (ax)^{n-k-1} a_y^{k-1} a_1 a_2, \\ \frac{\partial^2 u_2}{\partial x_2 \partial y_2} &= (n-k)k (ax)^{n-k-1} a_y^{k-1} (-a_1 a_2), \end{aligned}$$

we find that they both satisfy the partial differential equation of the second order

$$\frac{\partial^2 u}{\partial x_1 \partial y_1} + \frac{\partial^2 u}{\partial x_2 \partial y_2} = 0;$$

and the operation indicated occupies the same position in regard to the new forms that the Ω process does in regard to polars.

Gordan finds it convenient sometimes to denote the Ω operation by $\left| \begin{smallmatrix} x_1 x_2 \\ y_1 y_2 \end{smallmatrix} \right| = (xy)$ symbolically. In the same symbolism the new process O is denoted by $x_1 y_1 + x_2 y_2 = xy$.

Let
$$O(f) = \frac{1}{m \cdot n} \left(\frac{\partial^2 f}{\partial x_1 \partial y_1} + \frac{\partial^2 f}{\partial x_2 \partial y_2} \right),$$

the operand being any form $p_x^m q_y^n$.

Then
$$O a_x^m (y b)^n = (ab) a_x^{m-1} (y b)^{n-1},$$

and thence
$$O^k a_x^m (y b)^n = (ab)^k a_x^{m-k} (y b)^{n-k};$$

also
$$O(ax)^m b_y^n = (ab)(ax)^{m-1} b_y^{n-1},$$

and thence
$$O^k (ax)^m b_y^n = (ab)^k (ax)^{m-k} b_y^{n-k},$$

which should be compared with the result

$$\Omega^k a_x^m b_y^n = (ab)^k a_x^{m-k} b_y^{n-k}.$$

Moreover, it is easy to see that $(ax)^m (ya)^n$ satisfies the Ω equation, and that

$$\Omega^k (ax)^m (yb)^n = (ab)^k (ax)^{m-k} (yb)^{n-k}.$$

We may catalogue results as follows:—

$$\Omega^k a_x^m b_y^n = (ab)^k a_x^{m-k} b_y^{n-k},$$

$$O^k a_x^m b_y^n = a_b^k a_x^{m-k} b_y^{n-k},$$

$$\Omega^k a_x^m (by)^n = a_y^k a_x^{m-k} (by)^{n-k},$$

$$O^k a_x^m (yb)^n = (ab)^k a_x^{m-k} (yb)^{n-k},$$

$$\Omega^k (ax)^m b_y^n = a_b^k (ax)^{m-k} b_y^{n-k},$$

$$O^k (ax)^m b_y^n = (ab)^k (ax)^{m-k} b_y^{n-k},$$

$$\Omega^k (ax)^m (yb)^n = (ab)^k (ax)^{m-k} (yb)^{n-k},$$

$$O^k (ax)^m (yb)^n = a_b^k (ax)^{m-k} (yb)^{n-k}.$$

The important point is that we always obtain symbolic products when we operate with Ω or O on symbolic products. It is clear that we may write

$$\Omega^k O^l a_x^m b_y^n = (ab)^k a_b^l a_x^{m-k-l} b_y^{n-k-l},$$

$$\Omega^k O^l a_x^m (yb)^n = (-)^k a_b^l (ab)^k a_x^{m-k-l} (yb)^{n-k-l},$$

$$\Omega^k O^l (ax)^m b_y^n = (-)^l a_b^k (ab)^l (ax)^{m-k-l} b_y^{n-k-l},$$

$$\Omega^k O^l (ax)^m (yb)^n = (ab)^k a_b^l (ax)^{m-k-l} (yb)^{n-k-l};$$

foreshadowing an extension of the process of transvection which will be reached later.

The co-polar processes, by which a_x^n is converted to $a_x^{n-k} (ya)^k$, and $(xa)^n$ to $(xa)^{n-k} a_y^k$, are representable by writing $x - ty$, $x_2 + ty_1$ for x_1, x_2 in a_x^n , and $x_1 + ty_2, x_2 - ty_1$ for x_1, x_2 in $(xa)^n$; for a_x^n becomes

$$\{a_x + t(ya)\}^n,$$

and $(xa)^n$ becomes

$$\{(xa) + ta_y\}^n.$$

The combined polar and co-polar process on a_x^n can be obtained by writing $x_1 + (yt)$, $x_2 + y_t$ for x_1, x_2 , and expanding in powers of t_1, t_2 ; for then a_x becomes $a_x + t_1(ya) + t_2 a_y$, the n^{th} power of which generates the functions; similarly if the function be $(xa)^n$ we can substitute $x_1 + t_y, x_2 + (ty)$ for x_1, x_2 , converting (xa) into $(xa) + t_1(ya) + t_2 a_y$, and the n^{th} power generates the polar functions.

To find the polar and co-polar functions of the product

$$F = a_x^m b_x^n = p_x^{m+n},$$

write

$$F_y^{k_1, k_2} = p_x^{m+n-k_1-k_2} (ya)^{k_1} p_y^{k_2}.$$

This, obviously, arises from p_x^{m+n} when we write $x_1 + (yt)$, $x_2 + y_t$ for x , and x_2 in p_x^{m+n} , and take the co-factor of $\binom{m+n}{k_1, k_2} t_1^{k_1} t_2^{k_2}$. Since

$$(p_x + t_1(y p) + t_2 p_y)^{m+n} = (a_x + t_1(ya) + t_2 a_y)^m (b_x + t_1(yb) + t_2 b_y)^n,$$

$$\binom{m+n}{k_1, k_2} F_y^{k_1, k_2} = \text{coefficient of } t_1^{k_1} t_2^{k_2} \text{ in the product}$$

$$(a_x + t_1(ya) + t_2 a_y)^m (b_x + t_1(yb) + t_2 b_y)^n.$$

Ex. gr. To find all the polars and co-polars of $a_x^3 b_x^2 = F$

$$\begin{aligned} (a_x + t_1(ya) + t_2 a_y)^3 &= a_x^3 + 3a_x^2(ya)t_1 + 3a_x a_y^2 t_2 + 3a_x(ya)^2 t_1^2 \\ &+ 6a_x(ya)a_y t_1 t_2 + 3a_x a_y^2 t_2^2 + (ya)^3 t_1^3 + 3(ya)^2 a_y t_1^2 t_2 + 3(ya)a_y^2 t_1 t_2^2 + a_y^3 t_2^3. \\ (b_x + t_1(yb) + t_2 b_y)^2 &= b_x^2 + 2b_x(yb)t_1 + 2b_x b_y t_2 \\ &+ (yb)^2 t_1^2 + 2(yb)b_y t_1 t_2 + b_y^2 t_2^2. \end{aligned}$$

Multiplying and applying the formulas

$$F_y^{0,0} = a_x^3 b_x^2,$$

$$F_y^{1,0} = \frac{2}{5} a_x^2 b_x (yb) + \frac{3}{5} a_x^2 b_x^2 (ya),$$

$$F_y^{0,1} = \frac{2}{5} a_x^2 b_x b_y + \frac{3}{5} a_x^2 b_x^2 a_y,$$

$$F_y^{2,0} = \frac{1}{10} a_x^3 (yb)^2 + \frac{3}{5} a_x^2 b_x (ya)(yb) + \frac{3}{10} a_x b_x^2 (ya)^2,$$

$$F_y^{1,1} = \frac{1}{10} a_x^3 b_y (yb) + \frac{3}{10} a_x^2 b_x b_y (ya) + \frac{3}{10} a_x^2 b_x a_y (yb) + \frac{3}{10} a_x b_x^2 a_y (ya),$$

$$F_y^{0,2} = \frac{1}{10} a_x^3 b_y^2 + \frac{3}{5} a_x^2 b_x a_y b_y + \frac{3}{10} a_x b_x^2 a_y^2,$$

$$F_y^{3,0} = \frac{3}{10} a_x^3 (ya)(yb)^2 + \frac{3}{5} a_x b_x (ya)^2 (yb) + \frac{1}{10} b_x^2 (ya)^3,$$

$$\begin{aligned} F_y^{2,1} &= \frac{3}{5} a_x^2 b_y (ya)(yb) + \frac{1}{10} a_x^2 a_y (yb)^2 + \frac{1}{5} a_x b_x b_y (ya)^2 + \frac{2}{5} a_x b_x a_y (ya)(yb) \\ &+ \frac{1}{10} b_x^2 a_y (ya)^2, \end{aligned}$$

$$\begin{aligned} F_y^{1,2} &= \frac{1}{10} a_x^2 b_y^2 (ya) + \frac{1}{5} a_x^2 a_y b_y (yb) + \frac{2}{5} a_x b_x a_y b_y (ya) + \frac{1}{5} a_x b_x a_y^2 (yb) \\ &+ \frac{1}{10} b_x^2 a_y^2 (ya), \end{aligned}$$

$$F_y^{0,3} = \frac{3}{10} a_x^2 a_y b_y^2 + \frac{3}{5} a_x b_x a_y^2 b_y + \frac{1}{10} b_x^2 a_y^3,$$

$$F_y^{4,0} = \frac{3}{5} a_x (ya)^2 (yb)^2 + \frac{2}{5} b_x (ya)^3 (yb),$$

$$\begin{aligned} F_y^{3,1} &= \frac{3}{10} a_x b_y (ya)^2 (yb) + \frac{3}{10} a_x a_y (ya)(yb)^2 + \frac{1}{10} b_x b_y (ya)^3 \\ &+ \frac{3}{10} b_x a_y (ya)^2 (yb), \end{aligned}$$

$$\begin{aligned} F_y^{2,2} &= \frac{1}{10} a_x b_y^2 (ya)^2 + \frac{2}{5} a_x a_y b_y (ya)(yb) + \frac{1}{10} a_x a_y^2 (yb)^2 + \frac{1}{5} b_x a_y b_y (ya)^2 \\ &+ \frac{1}{5} b_x a_y^2 (ya)(yb), \end{aligned}$$

$$F_y^{1,3} = \frac{3}{10} a_x a_y b_y^2 (ya) + \frac{3}{10} a_x a_y^2 b_y (yb) + \frac{3}{10} b_x a_y^2 b_y (ya) + \frac{1}{10} b_x a_y^3 (yb),$$

$$F_y^{0,4} = \frac{3}{5} a_x a_y^2 b_y^2 + \frac{2}{5} b_x a_y^3 b_y,$$

$$F_y^{5,0} = (ya)^3 (yb)^2,$$

$$F_y^{4,1} = \frac{2}{5} b_y (ya)^3 (yb) + \frac{3}{5} a_y (ya)^2 (yb)^2,$$

$$F_y^{3,2} = \frac{1}{10} b_y^2 (ya)^3 + \frac{3}{5} a_y b_y (ya)^2 (yb) + \frac{3}{10} a_y^2 (ya)(yb)^2,$$

$$F_y^{2,3} = \frac{3}{10} a_y b_y^2 (ya)^2 + \frac{3}{5} a_y^2 b_y (ya)(yb) + \frac{1}{10} a_y^3 (yb)^2,$$

$$F_y^{1,4} = \frac{3}{5} a_y^2 b_y^2 (ya) + \frac{2}{5} a_y^3 b_y (yb),$$

$$F_y^{0,5} = a_y^3 b_y^2.$$

Of any order, $k_1 + k_2 = k$, there are $k+1$ polars corresponding to the binary compositions of k . It will be remarked that the sum of the coefficients of the terms of the polar is always unity. A term, without its numerical coefficient, is termed a member of the polar. If we take a member of the polar $F_y^{k_1, k_2}$ and put in it $b = a$, we obtain $a_y^{k_2} (ya)^{k_1}$; and this is exactly what we obtain on putting $b = a$ in $F_y^{k_1, k_2}$; hence, making this substitution, we find that the sum of the coefficient of the members is unity. What we may call the leading member of $F_y^{k_1, k_2}$, where $F = a_x^m b_x^n$ involves k_1 factors of the kind (ya) or (yb) ; say $(ya)_{k_1} (yb)_{k_2}$ where $k_{11} + k_{12} = k_1$; and also k_2 factors of the kind a_y or b_y say $a_y^{k_{21}} b_y^{k_{22}}$ where $k_{21} + k_{22} = k_2$. So the member may be written $a_x^{m-k_{11}-k_{12}-k_{21}-k_{22}} b_x^{n-k_{11}-k_{12}-k_{21}-k_{22}} (ya)^{k_{11}} (yb)^{k_{12}} a_y^{k_{21}} b_y^{k_{22}}$. We may arrange the members (i.) in descending order as regards the exponent of a_x ;

(ii.) in descending order as regards the exponents of b_y and (ya) ; (iii.) in ascending order in regard to the exponents of a_y , (yb) , and b_x . We have then the notion of adjacent members, and we can show that the difference between any two adjacent members is either divisible by $(ab)(xy)$, $(ab)x_y$, or $(ab)y_x$, and the theory of the polar members may be proceeded with in the usual manner.

The process of transvection can be extended in the same way as the polar process. Of two forms

$$f = a_x^m, \phi = b_x^n$$

we define the transvectant of orders k, l to be

$$(f, \phi)^{k,l} = \left\{ \Omega^k \Omega^l a_x^m b_x^n \right\}_{y=x} \\ = (ab)^k a_b^l a_x^{m-k-l} b_x^{n-k-l};$$

and similarly

$$\left\{ a_x^m, (xb)^n \right\}^{k,l} = (-)^k a_b^k (ab)^l a_x^{m-k-l} (xb)^{n-k-l}, \\ \left\{ (xa)^m, b_x^n \right\}^{k,l} = (-)^l a_b^l (ab)^k a_x^{m-k-l} b_x^{n-k-l}, \\ \left\{ (xa)^m, (xb)^n \right\}^{k,l} = (ab)^k a_b^l (xa)^{m-k-l} (xb)^{n-k-l};$$

and if the forms be

$$\phi_x^m, \psi_x^n, \\ (\phi_x^m, \psi_x^n)^{k,l} = (\phi\psi)^k \phi_\psi^l a_x^{m-k-l} \psi_x^{n-k-l};$$

and similarly

$$\left\{ (x\phi)^m, (x\psi)^n \right\}^{k,l} = (\phi\psi)^k \phi_\psi^l (x\phi)^{m-k-l} (x\psi)^{n-k-l};$$

and the intermediate processes also in the same way. Taking as before $f = a_x^m, \phi = b_x^n$, we find that the process of transvection of order $k+l$ is equivalent to the performance of the differential operation

$$\left(\frac{\partial f}{\partial a_1} \frac{\partial \phi}{\partial a_2} - \frac{\partial f}{\partial a_2} \frac{\partial \phi}{\partial a_1} \right)^k \left(\frac{\partial f}{\partial a_1} \frac{\partial \phi}{\partial a_1} + \frac{\partial f}{\partial a_2} \frac{\partial \phi}{\partial a_2} \right)^l;$$

omitting a mere numerical factor. The multiplication of operations is, of course, symbolic, so that

$$\left(\frac{\partial f}{\partial a_1} \right)^i \left(\frac{\partial f}{\partial a_2} \right)^j = \frac{\partial^{i+j} f}{\partial a_1^i \partial a_2^j}.$$

We will now give some examples of transvectants.

Ex. gr. if $f = a_x^2, \phi = b_x^2$

$$(f, \phi)^{0,0} = a_x^2 b_x^2$$

$$(f, \phi)^{1,0} = (ab) a_x b_x = (\bar{a}_0 \bar{b}_1 - \bar{a}_1 \bar{b}_0) x_1^2 + (\bar{a}_0 \bar{b}_2 - \bar{a}_2 \bar{b}_0) x_1 x_2 + (\bar{a}_1 \bar{b}_2 - \bar{a}_2 \bar{b}_1) x_2^2;$$

$$(f, \phi)^{0,1} = a_x a_x b_x = (\bar{a}_0 \bar{b}_0 + \bar{a}_1 \bar{b}_1) x_1^2 + (\bar{a}_0 \bar{b}_1 + \bar{a}_1 \bar{b}_0 + \bar{a}_1 \bar{b}_2 + \bar{a}_2 \bar{b}_1) x_1 x_2 + (\bar{a}_1 \bar{b}_1 + \bar{a}_2 \bar{b}_2) x_2^2;$$

$$(f, \phi)^{2,0} = (ab)^2 = \bar{a}_0 \bar{b}_2 - 2\bar{a}_1 \bar{b}_1 + \bar{a}_2 \bar{b}_0;$$

$$(f, \phi)^{1,1} = (ab) a_b = \bar{a}_0 \bar{b}_1 - \bar{a}_1 \bar{b}_0 + \bar{a}_1 \bar{b}_2 - \bar{a}_2 \bar{b}_1;$$

$$(f, \phi)^{0,2} = a_b^2 = \bar{a}_0 \bar{b}_0 + 2\bar{a}_1 \bar{b}_1 + \bar{a}_2 \bar{b}_2;$$

five orthogonal concomitants of two simultaneous quadratics obtained by simple transvection. If a, b be alternative symbols $(f, f')^{1,0}$ and $(f, f')^{0,1}$ vanish identically, and we are left with the quadratic covariant

$$(f, f')^{0,1} = (\bar{a}_0^2 + \bar{a}_2^2) x_1^2 + 2(\bar{a}_0 \bar{a}_1 + \bar{a}_1 \bar{a}_2) x_1 x_2 + (\bar{a}_1^2 + \bar{a}_2^2) x_2^2;$$

and the two invariants

$$(f, f')^{2,0} = 2(\bar{a}_0 \bar{a}_2 - \bar{a}_1^2), (f, f')^{0,2} = \bar{a}_0^2 + 2\bar{a}_1^2 + \bar{a}_2^2.$$

We may proceed by transvection from the forms $(xa)a_x$ and $(xa)^2$. Observe that

$$(xa)a_x = \bar{a}_1 x_1^2 - (\bar{a}_0 - \bar{a}_2) x_1 x_2 - \bar{a}_1 x_2^2,$$

$$(xa)^2 = \bar{a}_2 x_1^2 - 2\bar{a}_1 x_1 x_2 + \bar{a}_0 x_2^2;$$

thus

$$\left\{ (xa)^2, b_x^2 \right\}^{1,0} = a_b (xa) b_x \\ = (\bar{a}_1 \bar{b}_0 + \bar{a}_2 \bar{b}_1) x_1^2 - (\bar{a}_0 \bar{b}_0 - \bar{a}_2 \bar{b}_2) x_1 x_2 - (\bar{a}_0 \bar{b}_1 + \bar{a}_1 \bar{b}_2) x_2^2; \\ \left\{ (xa)^2, b_x^2 \right\}^{0,1} = - (ab) (xa) b_x \\ = - \left\{ (\bar{a}_1 \bar{b}_1 - \bar{a}_2 \bar{b}_0) x_1^2 + (-\bar{a}_0 \bar{b}_1 + \bar{a}_1 \bar{b}_0 + \bar{a}_1 \bar{b}_2 - \bar{a}_2 \bar{b}_1) x_1 x_2 + (\bar{a}_1 \bar{b}_1 - \bar{a}_0 \bar{b}_2) x_2^2 \right\}; \\ \left\{ (xa)^2, (xb)^2 \right\}^{1,0} = (ab) (xa) (xb) \\ = (\bar{a}_1 \bar{b}_2 - \bar{a}_2 \bar{b}_1) x_1^2 - (\bar{a}_0 \bar{b}_2 - \bar{a}_2 \bar{b}_0) x_1 x_2 + (\bar{a}_0 \bar{b}_1 - \bar{a}_1 \bar{b}_0) x_2^2;$$

where observe that this form is obtained from $(ab)a_x b_x$ by writing $-x_2, x_1$ in place of x_1, x_2 , a process which is always invariant. From one covariant we can in this way always derive another of

the same degree-order. To see how this is take the linear operator

$$x_1 \frac{\partial}{\partial a_2} - x_2 \frac{\partial}{\partial a_1} = \left(x \frac{\partial}{\partial a} \right),$$

and further the operator of order k

$$\left(x_1 \frac{\partial}{\partial a} - x_2 \frac{\partial}{\partial a} \right)^k = \left(x \frac{\partial}{\partial a} \right)^k,$$

obtained by symbolic expansion.

Then

$$\left(x \frac{\partial}{\partial a} \right) a_x^n = \frac{n!}{(n-k)!} (xa)^k a_x^{n-k}, \\ \left(x \frac{\partial}{\partial a} \right)^k (xa)^n = (-)^k \frac{n!}{(n-k)!} (xa)^{n-k} a_x^k;$$

so that

$$\frac{1}{n!} \left(x \frac{\partial}{\partial a} \right)^n a_x^n = (xa)^n, \\ \frac{(-)^n}{n!} \left(x \frac{\partial}{\partial a} \right)^n (xa)^n = a_x^n,$$

and

$$\frac{(-)^n}{(n!)^2} \left(x \frac{\partial}{\partial a} \right)^n \left(x \frac{\partial}{\partial a} \right)^n a_x^n = a_x^n.$$

Hence the operation of writing $-x_2, x_1$ in place of x_1, x_2 in any form a_x^n or $(xa)^n$ is, disregarding a numerical factor, equal to the performance of $\left(x \frac{\partial}{\partial a} \right)^n$, an operation of order n . Hence, when this operation is performed upon any symbolic product

$$(xa)^p (xb)^q \dots a_x^s b_x^t \dots$$

of order n in x , it effectively produces

$$a_x^{p+q} \dots (xa)^s (xb)^t \dots$$

The operations

$$\left(x \frac{\partial}{\partial a} \right), \left(x \frac{\partial}{\partial a} \right)^2, \dots \left(x \frac{\partial}{\partial a} \right)^n,$$

when performed upon a_x^n or $(xa)^n$ produce the $n+1$ covariants, of order n ,

$$a_x^n, (xa)a_x^{n-1}, (xa)^2 a_x^{n-2}, \dots (xa)^n;$$

which we may conceive to be generated by the expansion of $\{a_x + \lambda(xa)\}^n$; that is to say, by giving, in a_x^n, a_1, a_2 the increments $+\lambda a_2, -\lambda a_1$, respectively. We have a relation connecting any two quasi-adjacent covariants of the series, for since

$$a_x^2 + (xa)^2 = a_x a_x,$$

$$(xa)^{\rho-2} a_x^{n-\rho+2} + (xa)^\rho a_x^{n-\rho} = a_x (xa)^{\rho-2} a_x^{n-\rho} a_x;$$

which shows that the sum of every two quasi-adjacent covariants contains the factor $a_x a_x$. The identity obtains whether n be the order of the original form or no. From it may be derived others of the kind

$$(xa)^{\rho-2} a_x^{n-\rho+2} + 2(xa)^\rho a_x^{n-\rho} + (xa)^{\rho+2} a_x^{n-\rho-2} \\ = a_x^2 (xa)^{\rho-2} a_x^{n-\rho-2} a_x^{n-\rho-2} a_x^2.$$

These relations indicate that these covariants do not constitute a fundamentally irreducible set of covariants; for the covariant $a_x (xa)^{\rho-2} a_x^{n-\rho} a_x$, is the product of $a_x (xa)^{\rho-2} a_x^{n-\rho}$, a_x , each of which is a covariant; and similarly $a_x^2 (xa)^{\rho-2} a_x^{n-\rho-2} a_x^2$ is the product of $a_x^2 (xa)^{\rho-2} a_x^{n-\rho-2}$ and a_x^2 , each of which is a covariant. Between the $n+1$ covariants we can establish $n-1$ independent relations giving $n-1$ reductions; the system is therefore reduced to two forms which we may take to be a_x^n and $(xa)a_x^{n-1}$. So also,

in regard to any covariant ϕ_x^n , we need only consider the further form $(x\phi)\phi_x^{n-1}$,

A process, somewhat similar to transvection, may like $\left(x \frac{\partial}{\partial a} \right)$ be performed upon a single form; this is

$$\frac{\partial^2}{\partial x_1^2} + \frac{\partial^2}{\partial x_2^2} = \frac{\partial}{\partial x} \frac{\partial}{\partial x}$$

in analogy with the notation $x_1^2 + x_2^2 = x_x$.

We have

$$\frac{1}{2!} \left(\frac{\partial^2}{\partial x_1^2} + \frac{\partial^2}{\partial x_2^2} \right) a_x^n = \binom{n}{2} a_x a_x^{n-2},$$

a covariant of degree-order 1, $n-2$.

While, in general,

$$\left(\frac{\partial^2}{\partial x_1^2} + \frac{\partial^2}{\partial x_2^2}\right)^k \alpha_x^n = \frac{n!}{(n-2k)!} \alpha_x^{n-2k},$$

$$\left(\frac{\partial^2}{\partial x_1^2} + \frac{\partial^2}{\partial x_2^2}\right)^k (x\alpha)^n = \frac{n!}{(n-2k)!} \alpha_x^k (x\alpha)^{n-2k}.$$

To these results it is useful to add

$$\left(\frac{\partial^2}{\partial x_1^2} + \frac{\partial^2}{\partial x_2^2}\right)^k \alpha_x^{n-1} (x\alpha) = \frac{(n-1)!}{(n-2k-1)!} \alpha_x^k \alpha_x^{n-2k-1} (x\alpha).$$

Ex. gr. from the quadratic α_x^2 we derive
 $\alpha_a = \alpha_1^2 + \alpha_2^2 = \bar{\alpha}_0 + \bar{\alpha}_2,$

from the cubic α_x^3 the linear covariant

$$\alpha_a \alpha_x = (\bar{\alpha}_0 + \bar{\alpha}_2)x_1 + (\bar{\alpha}_1 + \bar{\alpha}_3)x_2,$$

and from the cubic covariant $\alpha_x^3(x\alpha)$ of the cubic

$$\alpha_a(x\alpha) = (\bar{\alpha}_1 + \bar{\alpha}_3)x_1 - (\bar{\alpha}_0 + \bar{\alpha}_2)x_2,$$

a linear covariant otherwise obtainable by operating upon $\alpha_a \alpha_x$ with

$$\frac{\partial}{\partial x_1} \frac{\partial}{\partial x_2} - x_2 \frac{\partial}{\partial x_1}.$$

Similarly, from the quartic α_x^4 , we obtain the quadratic covariant

$$\alpha_a \alpha_x^2 = (\bar{\alpha}_0 + \bar{\alpha}_2)x_1^2 + 2(\bar{\alpha}_1 + \bar{\alpha}_3)x_1x_2 + (\bar{\alpha}_2 + \bar{\alpha}_4)x_2^2,$$

and the invariant

$$\alpha_a^2 = \bar{\alpha}_0 + 2\bar{\alpha}_2 + \bar{\alpha}_4.$$

It has been shown, by Sylvester, that all orthogonal covariants satisfy the partial differential equation

$$\alpha_0 \frac{\partial}{\partial \alpha_1} + 2\alpha_1 \frac{\partial}{\partial \alpha_2} + \dots + n\alpha_{n-1} \frac{\partial}{\partial \alpha_n} - \left\{ n\alpha_1 \frac{\partial}{\partial \alpha_0} + (n-1)\alpha_2 \frac{\partial}{\partial \alpha_1} + \dots + \alpha_n \frac{\partial}{\partial \alpha_{n-1}} \right\} + x_1 \frac{\partial}{\partial x_2} - x_2 \frac{\partial}{\partial x_1} = 0,$$

which, in the notation employed in a previous page, is

$$\Omega_a - O_a + \left(\frac{\partial}{\partial x}\right) = 0.$$

If then a covariant, of order ϵ to an n^{th} , be

$$\Sigma C_k \alpha_1^{\epsilon-k} \alpha_2^k,$$

the operation produces

$$\Sigma \left\{ x_1^{\epsilon-k} x_2^k (\Omega_a - O_a) C_k + C_k k x_1^{\epsilon-k+1} x_2^{k-1} - C_k (\epsilon-k) x_1^{\epsilon-k-1} x_2^{k+1} \right\},$$

the vanishing of which necessitates the relations which, writing $O_a - \Omega_a = V$, take the form

$$\begin{aligned} C_1 - VC_0 &= 0, \\ 2C_2 - VC_1 &= \epsilon C_0 = 0, \\ 3C_3 - VC_2 - (\epsilon-1)C_1 &= 0, \end{aligned}$$

$$\epsilon C_\epsilon - VC_{\epsilon-1} - 2C_{\epsilon-2} = 0;$$

and thence

$$\begin{aligned} C_1 &= VC_0, \\ 2C_2 &= \{(V^2+1) + (\epsilon-1)\} C_0, \\ 3!C_3 &= \{V(V^2+4) + 3(\epsilon-2)V\} C_0, \\ 4!C_4 &= \{(V^2+1)(V^2+9) + 6(\epsilon-3)(V^2+1) + 3(\epsilon-1)(\epsilon-3)\} C_0, \\ 5!C_5 &= \{V(V^2+4)(V^2+16) + 10(\epsilon-4)V(V^2+4) \\ &\quad + 15(\epsilon-2)(\epsilon-4)\} C_0; \end{aligned}$$

indicating the manner of obtaining the successive covariant coefficients when once the leading coefficient C_0 is known.

Ex. gr. Taking as leading coefficient α_0^2 , the order of the covariant is $2n-4$, and the three first terms

$$\begin{aligned} &(\alpha_0^2 + 2\alpha_1^2 + \alpha_2^2)x_1^{2n-4} \\ &+ 2(n-2)(\bar{\alpha}_0\bar{\alpha}_1 + 2\bar{\alpha}_1\bar{\alpha}_2 + \bar{\alpha}_2\bar{\alpha}_3)x_1^{2n-5}x_2 \\ &+ (n-2)\left\{(n-2)(\bar{\alpha}_1^2 + 2\bar{\alpha}_2^2 + \bar{\alpha}_3^2) + (n-3)(\bar{\alpha}_0\bar{\alpha}_2 + 2\bar{\alpha}_1\bar{\alpha}_3 + \bar{\alpha}_2\bar{\alpha}_4)\right\} \\ &\quad \times \alpha_1^{2n-6}\alpha_2^2 \\ &+ \dots \end{aligned}$$

It may be gathered, from the above relations, that, for covariants of orders 0, 1, 2, 3, 4, ..., the leading coefficients C_0 satisfy the equations

$$\begin{aligned} VC_0 &= 0, \\ (V^2+1)C_1 &= 0, \\ V(V^2+4)C_2 &= 0, \\ (V^2+1)(V^2+9)C_3 &= 0, \\ V(V^2+4)(V^2+16)C_4 &= 0, \end{aligned}$$

respectively. It is thus important to notice that for each order

of covariant we have a special differential equation. We can infer from the annihilating operator $V(V^2+4)$ for covariants of the second order that the function $(V^2+4)C_0$ is an invariant of the same binary form.

Ex. gr. For the binary quadratic α_x^2 , α_0 is the leading coefficient of the form itself, a covariant of the second order, and as a consequence the operation

$$\left(2\alpha_1 \frac{\partial}{\partial \alpha_0} + \alpha_2 \frac{\partial}{\partial \alpha_1} - \alpha_0 \frac{\partial}{\partial \alpha_1} - 2\alpha_1 \frac{\partial}{\partial \alpha_2}\right)^2 + 4$$

when performed upon α_0 must produce an invariant; it, in fact, produces the invariant

$$2(\bar{\alpha}_0 + \bar{\alpha}_2).$$

The annihilator, in respect of a covariant of order $2s$, is

$$V(V^2+2^2)(V^2+4^2)\dots(V^2+4s^2);$$

and if the order be $2s+1$

$$(V^2+1^2)(V^2+3^2)\dots(V^2+4s^2+4s+1);$$

so that, in general, the operation $V^2+\epsilon^2$ upon a leading coefficient of a covariant of order ϵ produces a leader of a covariant of order $\epsilon-2$ pertaining to the same binary form, and this must necessarily be of the same degree in the coefficients.

Ex. gr. From the Hessian of the cubic α_x^3 , viz., $(ab)^2\alpha_x b_x$, we thus obtain the invariant

$$\bar{\alpha}_0\bar{\alpha}_2 - \bar{\alpha}_1^2 + \bar{\alpha}_1\bar{\alpha}_3 - \bar{\alpha}_2^2 = \alpha_0(ab)^2.$$

It will be noticed that a source of a linear covariant is annihilated by V^2+1 .

The Boolean System.—The form is $\alpha_x^n = (\alpha_1 x_1 + \alpha_2 x_2)^n$, associated with the quadratic $x_1^2 + 2\cos \omega x_1 x_2 + x_2^2$. α_x^n is transformed to $\Lambda_x^n = (\Lambda_1 x_1 + \Lambda_2 x_2)^n$, by the substitutions

$$x_1 = \frac{\sin(\omega - \alpha)}{\sin \omega} X_1 + \frac{\sin(\omega - \beta)}{\sin \omega} X_2,$$

$$x_2 = \frac{\sin \alpha}{\sin \omega} X_1 + \frac{\sin \beta}{\sin \omega} X_2,$$

of modulus $\frac{\sin \omega'}{\sin \omega}$; where $\omega' = \beta - \alpha$.

The problem is to find functions of the original coefficients, variables, and ω , which by the transformation become the like functions of the new coefficients and variables and ω' , save as to a power of the modulus. α_x and (ab) clearly possess the invariant property.

$$\begin{aligned} \text{Put } \alpha_1 - \alpha_2 \cos \omega &= b_1 - b_2 \cos \omega = \dots = a_1 = \beta_1 = \dots, \\ \alpha_2 - \alpha_1 \cos \omega &= b_2 - b_1 \cos \omega = \dots = a_2 = \beta_2 = \dots \\ \alpha_1 + \alpha_2 \cos \omega &= \xi_1, \\ \alpha_2 + \alpha_1 \cos \omega &= \xi_2, \end{aligned}$$

where $\alpha_1, \alpha_2; \beta_1, \beta_2, \dots$ are new umbrae and ξ_1, ξ_2 are auxiliary variables.

Let the transformation convert α_1, α_2 into $\mathbf{A}_1, \mathbf{A}_2$, where

$$\begin{aligned} \mathbf{A}_1 &= \alpha_1 - \alpha_2 \cos \omega', \\ \mathbf{A}_2 &= \alpha_2 - \alpha_1 \cos \omega', \end{aligned}$$

and ξ_1, ξ_2 into Ξ_1, Ξ_2 , where

$$\begin{aligned} \Xi_1 &= X_1 + X_2 \cos \omega' = \cos \alpha x_1 + \cos(\omega - \alpha)x_2, \\ \Xi_2 &= X_2 + X_1 \cos \omega' = \cos \beta x_1 + \cos(\omega - \beta)x_2. \end{aligned}$$

Observe that

$$x \xi = \alpha_1 \xi_1 + \alpha_2 \xi_2 = x_1^2 + 2 \cos \omega x_1 x_2 + x_2^2.$$

Now

$$X_1 = \frac{\sin \beta}{\sin \omega'} x_1 - \frac{\sin(\omega - \beta)}{\sin \omega'} x_2,$$

$$X_2 = -\frac{\sin \alpha}{\sin \omega'} x_1 + \frac{\sin(\omega - \alpha)}{\sin \omega'} x_2,$$

$$\mathbf{A}_1 = \frac{\sin(\omega - \alpha)}{\sin \omega} \alpha_1 + \frac{\sin \alpha}{\sin \omega} \alpha_2,$$

$$\mathbf{A}_2 = \frac{\sin(\omega - \beta)}{\sin \omega} \alpha_1 + \frac{\sin \beta}{\sin \omega} \alpha_2,$$

$$\mathbf{A}_1 = \frac{\sin \omega'}{\sin \omega} \{ \cos(\omega - \beta) \alpha_1 - \cos \beta \alpha_2 \},$$

$$\mathbf{A}_2 = \frac{\sin \omega'}{\sin \omega} \{ -\cos(\omega - \alpha) \alpha_1 + \cos \alpha \alpha_2 \};$$

whence it can be shown that

$$\begin{aligned} (X\mathbf{A}) &= X_1 \mathbf{A}_2 - X_2 \mathbf{A}_1 = X_1(\mathbf{A}_2 - \mathbf{A}_1 \cos \omega') - X_2(\mathbf{A}_1 - \mathbf{A}_2 \cos \omega') \\ &= \frac{\sin \omega'}{\sin \omega} (x\alpha); \end{aligned}$$

from which we learn that $(x\alpha)$ possesses the invariant property. Further, it may be verified that

$$\mathbf{A}_\mathbf{A} = \left(\frac{\sin \omega'}{\sin \omega}\right)^2 \alpha_a; \quad \mathbf{A}_\mathbf{B} = \left(\frac{\sin \omega'}{\sin \omega}\right)^2 \alpha_\beta;$$

so that a_α, a_β possess, each of them, the invariant property. There are thus six invariant symbolic factors, viz., $(ab), a_\alpha, a_\beta, (x\alpha), a_x, x_\xi$; and from these types we are able to form invariant symbolic products. We must note the results—

$$(\xi a) = (x\alpha); a_\xi = \sin^2 \omega a_x; (a\beta) = \sin^2 \omega (ab)$$

$$(x\xi) = \cos \omega (a_1^2 - a_2^2); (x\alpha) = \cos \omega (a_1^2 - a_2^2).$$

Since $\sin^2 \omega$ is the discriminant of x_ξ we may regard a_ξ and $(a\beta)$ as reducible, and we take as the general form of invariant—

$$(ab)^{h_1} (ac)^{h_2} (bc)^{h_3} \dots a_\alpha^{i_1} a_\beta^{i_2} a_\gamma^{i_3} \dots a_\beta^{j_1} a_\gamma^{j_2} a_\gamma^{j_3} \dots \\ \times (x\alpha)^{k_1} (x\beta)^{k_2} (x\gamma)^{k_3} \dots a_x^{l_1} a_x^{l_2} a_x^{l_3} \dots x_\xi^m,$$

which should be contrasted with the corresponding expression for orthogonal invariants.

If this be of order ϵ and appertain to an $n^i c$:

$$\sum k + \sum l + 2m = \epsilon,$$

the pair of symbols a, α must together appear n times; so also for $b, \beta; c, \gamma; \dots$

We have the symbolic identities

$$b_\alpha = a_\beta, y_\xi = x_\eta;$$

$$a_\alpha b_\beta - a_\beta b_\alpha = (a\beta)(ab) = \sin^2 \omega (ab)^2;$$

$$a_\alpha x_\xi - (x\alpha)^2 = a_x a_\xi = \sin^2 \omega a_x^2;$$

$$(ab)c_\alpha + (bc)a_\alpha + (ca)b_\alpha = 0;$$

and many others, derivable from these, which are of assistance in the reduction of symbolic products. We may give here some simple examples of Boolean invariants.

Ex. gr. For the linear form $a_x = b_x = \dots$, we have

$$(i.) a_x = \bar{a}_0 x_1 + \bar{a}_1 x_2,$$

$$(ii.) x_\xi^2 = x_1^2 + 2 \cos \omega x_1 x_2 + x_2^2,$$

$$(iii.) \sin^2 \omega,$$

$$(iv.) (x\alpha) = (\bar{a}_1 - \bar{a}_0 \cos \omega) x_1 - (a_0 - a_1 \cos \omega) x_2,$$

$$(v.) a_\beta = \bar{a}_0^2 - 2\bar{a}_0 \bar{a}_1 \cos \omega + \bar{a}_1^2.$$

For two linear forms (v.) yields the simultaneous invariant

$$\bar{a}_0 \bar{b}_0 + \bar{a}_1 \bar{b}_1 - \cos \omega (\bar{a}_0 \bar{b}_1 + \bar{a}_1 \bar{b}_0).$$

For the quadratic form $a_x^2 = b_x^2 = \dots$, we have the system

$$(i.) a_x^2,$$

$$(ii.) x_\xi^2,$$

$$(iii.) \sin^2 \omega,$$

$$(iv.) \frac{1}{2}(ab)^2 = \bar{a}_0 \bar{a}_2 - \bar{a}_1^2,$$

$$(v.) (x\alpha)a_x = (\bar{a}_1 - \bar{a}_0 \cos \omega) x_1^2 + (\bar{a}_2 - \bar{a}_0) x_1 x_2 + (\bar{a}_2 \cos \omega - \bar{a}_1) x_2^2,$$

which is the Jacobian of a_x^2 and x_ξ ;

$$(vi.) a_\alpha = \bar{a}_0 - 2 \cos \omega \bar{a}_1 + \bar{a}_2;$$

and it may be shown that all other covariants are rational integral functions of these six forms.

Again, take the quadratic $a_x^2 = b_x^2 = \dots$ and the linear form $a'_x = b'_x = \dots$; besides the forms, appertaining to the linear form and quadratic separately, which have been already given, we have four additional forms involving the coefficients of both forms, viz. :—

$$(aa')(ab') = \bar{a}_0 \bar{a}'_1 - 2\bar{a}_1 \bar{a}'_0 \bar{a}_1 + \bar{a}_2 \bar{a}'_0,$$

$$a'_\alpha (aa') = (a_1 - a_0 \cos \omega) \bar{a}'_1 + (\bar{a}'_0 - \bar{a}_2) \bar{a}'_0 \bar{a}_1 + (\bar{a}_2 \cos \omega - \bar{a}_1) \bar{a}'_0^2,$$

$$(aa')a_x = (\bar{a}'_0 \bar{a}_1 - \bar{a}_1 \bar{a}'_0) x_1 + (\bar{a}'_1 \bar{a}_1 - \bar{a}_2 \bar{a}'_0) x_2,$$

$$(x\alpha)(aa') = \{ \bar{a}'_0 \bar{a}_1 - \bar{a}_2 \bar{a}'_0 - \cos \omega (\bar{a}'_0 \bar{a}_1 - \bar{a}_1 \bar{a}'_0) \} x_1$$

$$- \{ \bar{a}'_0 \bar{a}_1 - \bar{a}_1 \bar{a}'_0 - \cos \omega (\bar{a}'_1 \bar{a}_1 - \bar{a}_2 \bar{a}'_0) \} x_2.$$

(See Elliott, *loc. cit.* p. 366).

The polar processes must now be examined. We have, η_1, η_2 , being cogredient with ξ_1, ξ_2 ,

$$\frac{(m-k)!}{m!} \left(y_1 \frac{\partial}{\partial x_1} + y_2 \frac{\partial}{\partial x_2} \right)^k a_x^m = a_x^{m-k} a_y^k,$$

$$\frac{(m-k)!}{m!} \left(y_1 \frac{\partial}{\partial x_1} + y_2 \frac{\partial}{\partial x_2} \right)^k (x\alpha)^m = (x\alpha)^{m-k} (y\alpha)^k,$$

$$\frac{(m-k)!}{m!} \left(\eta_1 \frac{\partial}{\partial \xi_1} + \eta_2 \frac{\partial}{\partial \xi_2} \right)^k a_x^m = a_x^{m-k} a_y^k,$$

$$\frac{(m-k)!}{m!} \left(\eta_1 \frac{\partial}{\partial \xi_1} + \eta_2 \frac{\partial}{\partial \xi_2} \right)^k (x\alpha)^m = (x\alpha)^{m-k} (y\alpha)^k,$$

$$\frac{(m-k)!}{m!} \left\{ \sin^2 \omega \left(y_1 \frac{\partial}{\partial \xi_2} - y_2 \frac{\partial}{\partial \xi_1} \right) \right\}^k a_x^m = a_x^{m-k} (y\alpha)^k,$$

$$\frac{(m-k)!}{m!} \left(y_1 \frac{\partial}{\partial \xi_2} - y_2 \frac{\partial}{\partial \xi_1} \right)^k (x\alpha)^m = (x\alpha)^{m-k} a_y^k,$$

$$\frac{(m-k)!}{m!} \left(\eta_1 \frac{\partial}{\partial x_2} - \eta_2 \frac{\partial}{\partial x_1} \right)^k a_x^m = a_x^{m-k} (y\alpha)^k,$$

$$\frac{(m-k)!}{m!} \left\{ \sin^2 \omega \left(\eta_1 \frac{\partial}{\partial x_2} - \eta_2 \frac{\partial}{\partial x_1} \right) \right\}^k (x\alpha)^m = (x\alpha)^{m-k} a_y^k;$$

from which it appears that, as regards a_x^m , we need only consider the operations

$$y_1 \frac{\partial}{\partial x_1} + y_2 \frac{\partial}{\partial x_2} \text{ and } \eta_1 \frac{\partial}{\partial x_2} - \eta_2 \frac{\partial}{\partial x_1};$$

and, as regards $(x\alpha)^m$, only

$$y_1 \frac{\partial}{\partial x_1} + y_2 \frac{\partial}{\partial x_2} \text{ and } y_1 \frac{\partial}{\partial \xi_2} - y_2 \frac{\partial}{\partial \xi_1};$$

and we have the processes

$$\frac{(m-k_1-k_2)!}{m!} \left(y_1 \frac{\partial}{\partial x_1} + y_2 \frac{\partial}{\partial x_2} \right)^{k_1} \left(\eta_1 \frac{\partial}{\partial x_2} - \eta_2 \frac{\partial}{\partial x_1} \right)^{k_2} a_x^m \\ = a_x^{m-k_1-k_2} a_y^{k_1} (y\alpha)^{k_2};$$

$$\frac{(m-k_1-k_2)!}{m!} \left(y_1 \frac{\partial}{\partial x_1} + y_2 \frac{\partial}{\partial x_2} \right)^{k_1} \left(y_1 \frac{\partial}{\partial \xi_2} - y_2 \frac{\partial}{\partial \xi_1} \right)^{k_2} (x\alpha)^m \\ = (x\alpha)^{m-k_1-k_2} (a_y)^{k_1} a_y^{k_2}.$$

The two forms $a_x^{m-k} a_y^k, (x\alpha)^{m-k} (y\alpha)^k$, satisfy the partial differential equation

$$\frac{\partial^2 u_1}{\partial x_1 \partial y_2} - \frac{\partial^2 u_1}{\partial x_2 \partial y_1} = 0;$$

and the two forms $a_x^{m-k} (y\alpha)^k, (x\alpha)^{m-k} a_y^k$, the partial differential equation

$$\frac{\partial^2 u_2}{\partial x_1 \partial \eta_1} + \frac{\partial^2 u_2}{\partial x_2 \partial \eta_2} = 0;$$

to verify this statement recall that

$$(y\alpha) = (\eta a), a_\eta = \sin^2 \omega a_y.$$

Taking, as operand, any form $a_x^{m-k} a_y^k$, we write

$$\Omega = \frac{1}{(m-k)k} \left(\frac{\partial^2}{\partial x_1 \partial y_2} - \frac{\partial^2}{\partial x_2 \partial y_1} \right),$$

$$O_{\alpha, \eta} = \frac{1}{(m-k)k} \left(\frac{\partial^2}{\partial x_1 \partial \eta_1} + \frac{\partial^2}{\partial x_2 \partial \eta_2} \right),$$

and we can establish the relations

$$\Omega^{k_1} (O_{\alpha \eta} \sin^2 \omega)^{k_2} a_x^{m-k_1-k_2} a_y^{k_1+k_2} = (ab)^{k_1} a_\beta^{k_2} a_x^{m-k_1-k_2} a_y^{k_1+k_2},$$

$$\Omega^{k_1} O_{\alpha \eta}^{k_2} (y\beta)^n = (-)^{k_1} (ab)^{k_2} a_\beta^{k_1} a_x^{m-k_1-k_2} (y\beta)^{n-k_1-k_2},$$

$$\Omega^{k_1} O_{\alpha \eta}^{k_2} (x\alpha)^m a_y^n = (-)^{k_2} (ab)^{k_2} a_\beta^{k_1} (x\alpha)^{m-k_1-k_2} a_y^{n-k_1-k_2},$$

$$(\Omega \operatorname{cosec}^2 \omega)^{k_1} O_{\alpha \eta}^{k_2} (x\alpha)^m (y\beta)^n = (ab)^{k_1} a_\beta^{k_2} (x\alpha)^{m-k_1-k_2} (y\beta)^{n-k_1-k_2}.$$

From these relations, by putting $y=x$, we derive the processes of transvection, and we may write

$$\left(a_x^m, a_x^m \right)_{k_1, k_2} = (ab)^{k_1} a_\beta^{k_2} a_x^{m-k_1-k_2} a_x^{n-k_1-k_2},$$

$$\left\{ a_x^m, (x\beta)^n \right\}_{k_1, k_2} = a_\beta^{k_1} (ab)^{k_2} a_x^{m-k_1-k_2} a_x^{n-k_1-k_2},$$

$$\left\{ (x\alpha)^m, a_x^n \right\}_{k_1, k_2} = a_\beta^{k_1} (ab)^{k_2} (x\alpha)^{m-k_1-k_2} a_x^{n-k_1-k_2},$$

$$\left\{ (x\alpha)^m, (x\beta)^n \right\}_{k_1, k_2} = (ab)^{k_1} a_\beta^{k_2} (x\alpha)^{m-k_1-k_2} (x\beta)^{n-k_1-k_2}.$$

Of order $k=k_1+k_2$ there are $k+1$ transvectants, and k may have any value not greater than the least of the numbers m, n .

The process is practically equivalent to the performance of the differential operation

$$\left(\frac{\partial f}{\partial x_1} \frac{\partial \phi}{\partial x_2} - \frac{\partial f}{\partial x_2} \frac{\partial \phi}{\partial x_1} \right)_{k_1} \left(\frac{\partial f}{\partial x_1} \frac{\partial \phi}{\partial \xi_1} + \frac{\partial f}{\partial x_2} \frac{\partial \phi}{\partial \xi_2} \right)_{k_2},$$

the multiplication of operators being symbolic. We have next to consider the operation

$\left(\frac{\partial}{\partial \xi}\right) = x_1 \frac{\partial}{\partial \xi_2} - x_2 \frac{\partial}{\partial \xi_1}$, upon $a_x^m = (\sin^2 \omega)^{-m} a_x^m$; we find

$$\left(x_1 \frac{\partial}{\partial \xi_2} - x_2 \frac{\partial}{\partial \xi_1}\right) a_x^m = m(\sin^2 \omega)^{-m} a_x^{m-1}(xa) = \frac{m}{\sin^2 \omega} a_x^{m-1}(xa);$$

∴ Calling the operation

$$\frac{1}{m} \sin^2 \omega \left(x_1 \frac{\partial}{\partial \xi_2} - x_2 \frac{\partial}{\partial \xi_1}\right),$$

when performed upon a_x^m , P, we have $P^k a_x^m = (xa)^k a_x^{m-k}$;

P^k is, in fact, $\frac{(m-k)!}{m!} \sin^{2k} \omega \left(x_1 \frac{\partial}{\partial \xi_2} - x_2 \frac{\partial}{\partial \xi_1}\right)^k$,

the operator being expanded symbolically. Similarly

$$(-)^k \frac{(m-k)!}{m!} \left(x \frac{\partial}{\partial \xi}\right)^k (xa)^m = (xa)^{m-k} a_x^k.$$

Hence

$$\left(\frac{\partial}{\partial \xi}\right)^m$$

has the effect, practically, of converting a_x^m into $(xa)^m$; this can be otherwise accomplished by writing $-x_2, x_1$ in place of x_1, x_2 , and changing a into α . $(xa)^m$ is similarly converted into a_x^m , only here α is changed into a . If the operand be $a_x^{m-k} (xa)^k$ it becomes converted by the operation into $(xa)^{m-k} a_x^k$. The covariants of the series $(xa)^k a_x^{m-k}$ are all reducible except a_x^m and $(xa)a_x^{m-1}$, as may be seen from the identities

$$\begin{aligned} \sin^2 \omega (xa)^k a_x^{m-k} + (xa)^{k+2} a_x^{m-k-2} \\ = (xa)^k a_x^{m-k-2} \{ \sin^2 \omega a_x^2 + (xa)^2 \} \\ = a_x (xa)^k a_x^{m-k-2} x_\xi^2; \end{aligned}$$

which exhibits the reduction of $(xa)^{k+2} a_x^{m-k-2}$. Next consider the operation of

$$\frac{\partial^2}{\partial x_1 \partial \xi_1} + \frac{\partial^2}{\partial x_2 \partial \xi_2},$$

upon a_x^m and $(xa)^m$. We find

$$\sin^{2k} \omega \left(\frac{\partial^2}{\partial x_1 \partial \xi_1} + \frac{\partial^2}{\partial x_2 \partial \xi_2}\right)^k a_x^m = \frac{m!}{(m-2k)!} a_x^k a_x^{m-2k},$$

$$\left(\frac{\partial^2}{\partial x_1 \partial \xi_1} + \frac{\partial^2}{\partial x_2 \partial \xi_2}\right)^k (xa)^m = \frac{m!}{(m-2k)!} a_x^k (xa)^{m-2k},$$

$$\sin^{2k} \omega \left(\frac{\partial^2}{\partial x_1 \partial \xi_1} + \frac{\partial^2}{\partial x_2 \partial \xi_2}\right)^k a_x^{m-1} (xa) = \frac{(m-1)!}{(m-2k-1)!} a_x^k a_x^{m-2k-1} (xa).$$

Before proceeding to give examples of these processes it must be observed that the transvectant

$$(a_x^m, b_x^n)^0, k_2$$

is always reducible where k_2 is even. This arises from the symbolic identity

$$\sin^2 \omega (ab)^2 + a_\beta^2 = a_\alpha b_\beta;$$

for, thence,

$$(a_x^m, b_x^n)^0, 2 + \sin^2 \omega (a_x^m, b_x^n)^2, 0 = (a_\alpha a_x^{m-2}, b_\beta b_x^{n-2}),$$

$$\begin{aligned} (a_x^m, b_x^n)^0, 4 + 2 \sin^2 \omega (a_x^m, b_x^n)^2, 2 + \sin^4 \omega (a_x^m, b_x^n)^4, 0 \\ = (a_\alpha a_x^{m-4}, b_\beta b_x^{n-4}), \end{aligned}$$

with similar identities which establish the theorem.

Ex. gr. Consider transvectants of a_x^3 over b_x^2

$$(a_x^3, b_x^2)^1, 0 = (ab) a_\alpha^2 b_\beta^2,$$

$$(a_x^3, b_x^2)^0, 1 = a_\beta a_\alpha b_\beta^2; \text{ which, for the single cubic } a_x^3 \text{ gives}$$

$$\begin{aligned} (a^2 - 2ab \cos \omega + b^2) x^4 + 4 \{ ab - (ac + b^2) \cos \omega + bc \} x^3 y \\ + 2 \{ ac + 2b^2 - (ad + 5bc) \cos \omega + bd + 2c^2 \} x^2 y^2 \\ + 4 \{ bc - (bd + c^2) \cos \omega + cd \} x y^3 \\ + (c^2 - 2cd \cos \omega + d^2) y^4, \end{aligned}$$

which is unchanged when a, b, c, d, x, y are changed into $\bar{a}, \bar{c}, \bar{b}, \bar{a}, y, x$ respectively.

$$(a_x^3, b_x^2)^2, 0 = (ab)^2 a_\alpha b_\beta,$$

$$(a_x^3, b_x^2)^1, 1 = (ab) a_\beta a_\alpha b_\beta, \text{ which vanishes for the single cubic,}$$

$$(a_x^3, b_x^2)^3, 0 = (ab)^3,$$

$$(a_x^3, b_x^2)^2, 1 = (ab)^2 a_\beta; \text{ which for a single cubic, is}$$

$$2 \{ (ac - b^2) - (ad - bc) \cos \omega + (bd - c^2) \}.$$

$(a_x^3, b_x^2)^1, 2 = (ab) a_\beta^2$; which vanishes for a single cubic, but, for two cubics, is

$$\begin{aligned} ab' - ba' + 2(bc' - cb') + (cd' - dc') \\ - 2(ac' - ca' + bd' - db') \cos \omega \\ + (ad' - da' + bc' - cb') \cos^2 \omega. \end{aligned}$$

$(a_x^3, b_x^2)^0, 3 = a_\beta^3$ which, for a single cubic, is

$$\begin{aligned} a^3 + 3b^2 + 3c^2 + d^2 - 6(ab + 2bc + cd) \cos \omega \\ + 6(ac + b^2 + bd + c^2) \cos^2 \omega - 2(ad + 3bc) \cos^3 \omega. \end{aligned}$$

Again the linear covariant $a_\alpha a_x$ is

$$(a - 2b \cos \omega + c)x + (b - 2c \cos \omega + d)y;$$

and the linear covariant $a_\alpha (xa)$ is

$$\begin{aligned} \{ b + d - (a + 3c) \cos \omega + 2b \cos^2 \omega \} x \\ - \{ a + c - (3b + d) \cos \omega + 2c \cos^2 \omega \} y. \end{aligned}$$

An invariant of the cubic which is of the fourth degree in the coefficients is

$$a_\beta^2 c_\beta^2 a_\alpha b_\beta$$

which is derived from

$$(ab)^2 (cd)^2 (ac)(bd)$$

by an obvious method of universal application. Generally, from any covariant given by its symbolic product in the theory of the general linear substitution, we may derive a conjugate form by writing m_ν for (mn) and $(x\mu)$ for m_x , and we are permitted to do this whether or no the former ultimately vanishes; the conjugate cannot vanish. In the general Boolean theory, in any symbolic product, we can pass to a conjugate form by writing

$$m_\nu \text{ for } (mn), (mn) \text{ for } m_\nu, (x\mu) \text{ for } m_x, m_x \text{ for } (x\mu).$$

A form, containing only a_x or x_ξ , will have no conjugates, and may be called a non-conjugate form. Other forms may have vanishing conjugates.

The differential equation, satisfied by Boolean covariants of the binary form a_x^n , has been shown, by Sylvester, to be

$$\cos \omega \left(x_1 \frac{\partial}{\partial x_1} - x_2 \frac{\partial}{\partial x_2}\right) + \left(x_2 \frac{\partial}{\partial x_1} - x_1 \frac{\partial}{\partial x_2}\right) + L = 0$$

$$\begin{aligned} \text{where } L = O_\alpha - \Omega_\alpha - \cos \omega \left\{ n a_{\alpha_0} \frac{\partial}{\partial a_\alpha} + (n-2) a_{\alpha_1} \frac{\partial}{\partial a_1} \right. \\ \left. + (n-4) a_{\alpha_2} \frac{\partial}{\partial a_2} + \dots + (n-2) a_{\alpha_{n-1}} \frac{\partial}{\partial a_{n-1}} + n a_{\alpha_n} \frac{\partial}{\partial a_n} \right\}; \end{aligned}$$

if then a covariant be

$$\Sigma C_k a_x^{\epsilon-k} x_\xi^k,$$

operation gives

$$\Sigma [(\epsilon - 2k) \cos \omega C_k x_1^{\epsilon-k} x_2^k + C_k \{ (\epsilon - k) x_1^{\epsilon-k-1} x_2^{k+1} - k x_1^{\epsilon-k+1} x_2^{k-1} \} + x_1^{\epsilon-k} x_2^k L \cdot C_k] = 0;$$

leading to

$$-(k+1)C_{k+1} + \{L + (\epsilon - 2k) \cos \omega\} C_k + (\epsilon - k + 1)C_{k-1} = 0,$$

and thence to the series of relations

$$\begin{aligned} -C_1 + (L + \epsilon \cos \omega) C_0 &= 0, \\ -2C_2 + \{L + (\epsilon - 2) \cos \omega\} C_1 + \epsilon C_0 &= 0, \\ -3C_3 + \{L + (\epsilon - 4) \cos \omega\} C_2 + (\epsilon - 1) C_1 &= 0, \\ -4C_4 + \{L + (\epsilon - 6) \cos \omega\} C_3 + (\epsilon - 2) C_2 &= 0, \end{aligned}$$

which may be written

$$\begin{aligned} C_1 &= (L + \epsilon \cos \omega) C_0, \\ 2C_2 &= \{L^2 + \sin^2 \omega + (\epsilon - 1)(\dots)\} C_0, \\ 6C_3 &= \{L(L^2 + 4 \sin^2 \omega) + (\epsilon - 2)(\dots)\} C_0 \\ 24C_4 &= \{L^2 + \sin^2 \omega\} (L^2 + 9 \sin^2 \omega) + (\epsilon - 3)(\dots) C_0. \end{aligned}$$

Hence for leading coefficients of covariants of orders $2s$ and $2s+1$ we have annihilators

$$\begin{aligned} L(L^2 + 2^2 \sin^2 \omega)(L^2 + 4^2 \sin^2 \omega) \dots (L^2 + 4s^2 \sin^2 \omega), \\ (L^2 + 1^2 \sin^2 \omega)(L^2 + 3^2 \sin^2 \omega) \dots \{L^2 + (4s+1)^2 \sin^2 \omega\} \end{aligned}$$

respectively. These conditions are necessary but plainly not sufficient; for every leading coefficient of a covariant, of even order $\equiv 2s$, satisfies the first operator and, of uneven order $\equiv 2s+1$, the second operator. We may say, however, that, if the order be $2s$, either

$$(L^2 + 4s^2 \sin^2 \omega) C_0 = 0,$$

or else $(L^2 + 4s^2 \sin^2 \omega) C_0$ is the leading coefficient of a covariant of even order $\equiv 2s-2$. Similarly, for uneven order $2s+1$, either

$$\{L^2 + (2s+1)^2 \sin^2 \omega\} C_0 = 0,$$

or $\{L^2 + (2s+1)^2 \sin^2 \omega\} C_0$, as the leading coefficient of a covariant of uneven order $\equiv 2s-1$.

Ex. gr. For order 3 of the cubic a_2^3 we find

$$(L^2 + 9 \sin^2 \omega) \bar{a}_0 = 6(\bar{a}_0 - 2\bar{a}_1 \cos \omega + \bar{a}_2),$$

where $\bar{a}_0 - 2\bar{a}_1 \cos \omega + \bar{a}_2$ appertains to the linear covariant $a_a a_x$; and it is easy to verify that $(L^2 + \sin^2 \omega) a_a a_x = 0$.

It is to be remarked that the sources of linear covariants are annihilated by $L^2 + \sin^2 \omega$. It has been customary for writers to regard the orthogonal and Boolean theories as particular cases of that arising from the general linear substitution. The above sketch will convince the reader that the latter theory is more properly viewed as a particular case of the former theories. Investigations, connected with this section, are a desideratum. No references can be given other than those alluded to, incidentally, in the text.

Algeria, in North Africa, the most important of the colonies of France, lies between Tunis on the east and Morocco on the west, and extends from the Mediterranean to the Sahara. Its area is estimated at 98,500,000 acres, or 153,906 square miles. The principal indentations of

reality of seventeen distinct ranges, among which it is sufficient to mention the Tlemcen range (5500 feet), the Warausenis (6000 feet), the Titéri range (4900 feet), the Jerjéra or Grand Kabyle range (7100 feet), with the peak of Lalla Kedija, and the Babor range (6000 feet).

SKETCH MAP OF ALGERIA.

the coast are the Gulf of Oran, the Gulf of Arzeu, the Bay of Algiers, the Gulfs of Bougie, Stora, and Bône. The ports are Nemours, Mers el Kebir, Oran, Arzeu, Mostaganem, Tenes, Cherchelle, Algiers, Dellys, Bougie, Jijelli, Collo, Philippeville, Bône, La Calle. Algeria is

The streams of the Tell are the Tafna (105 miles), the Macta, formed by the Sig and the Habra; the Cheliff (415 miles), the Isser (130 miles), the Sahel (125 miles), the Kebir (140 miles), the Seybouse (145 miles), and the Mejerda, which flows through Tunis to the sea. None of these rivers is navigable. The temperature of the Tell is moderated by the sea-breeze, but the sirocco wind sometimes brings scorching heat. The climate is very healthy, except in the extreme coast region. The high plateaus form a plain of an average height of from 2500 to 3000 feet, dominated by the ridges of the second or Saharan chain of the Atlas, of which the chief points are the Ksour (6000 feet), the Amour and the Aurès (7200 feet). At the foot and to the north of this chain, towards the middle of the plateaus, is a depression containing saline lakes or chotts, of which the best known are the Chergui and the Hodna. The rivers are unimportant; the temperature is variable, passing from one extreme to the other, and

rain seldom falls. The Saharan region consists of wide sandy or rocky plains without noteworthy features. The water in general remains under the surface; the temperature is very high by day; rain falls scarcely in one year out of three. Life exists only round the oases or cultivated places. Geologically, the Atlas of the Tell consists of crystalline rocks, schists, and lias. The Tertiary formation hardly ever appears except in its eastern portion. On the other hand, the Little or Saharan Atlas is essentially of Cretaceous and Jurassic formation, like the rocks of the desert itself.

Population.—The population consists of Kabyles or Berbers, Arabs, Moors, Jews, Turks, Coulouglis, Negroes, Mozabides, and

B. V. Darbishire & O. F. R. Howarth French Territory French Protectorate
MAP SHOWING THE POLITICAL POSITION OF ALGERIA.

naturally divided into three parts—the Tell, or coast region, with a breadth varying from 75 to 160 miles; the high plateaus; and the Sahara region. The Tell is traversed by the first chain of the Atlas, consisting in

	1881.	1896.
Native	2,850,886	3,847,448
French and naturalized	269,502	334,713
Other Europeans	190,014	211,535
Total	3,310,402	4,393,696

Europeans of various nationality. The Berber population is estimated at 75 per cent. and the Arab at 15 per cent. of the

whole, but this estimate, due to General Faidherbe, is not easy to verify. The total population increased from 3,310,402 in 1881 to 4,393,696 in 1896. In those years the numbers of the native and of the European inhabitants are shown in the above table.

According to these figures, the native element increased by 28 per cent., the French by 25 per cent., and the non-French European by 12 per cent.

Of the European (non-French) population in 1896, 63,205 lived in the department of Algiers, 113,279 in the department of Oran, 35,051 in the department of Constantine. About half the number were Spanish; after them came Italians, Maltese, Germans, &c.

In 1896 the area and population of the three departments and the population of the military territory in each department were as follows:—

Departments.	Area, Square Miles.	Total Population.	Population of Military Territory.
Algiers	65,929	1,526,667	213,461
Oran	44,616	1,028,248	140,071
Constantine	73,921	1,838,781	202,611
Total	184,466	4,393,696	556,143

The area of the Algerian Sahara is about 123,500 square miles, and the population about 50,000.

Movement of population.—During three years the registered marriages, births, and deaths were as follows:—

Years.	Marriages.	Births.	Deaths.	Surplus of Births.
1897	37,140	133,164	78,951	54,213
1898	36,484	123,674	87,671	36,003
1899	42,816	135,479	90,557	44,922

In 1897 the divorces numbered 12,267; in 1898, 11,876; in 1899, 12,364. In those years, respectively, the still-births numbered 2423, 2837, and 2803. Of the living births in 1899, 17,637 were European, 2464 Jewish, and 115,274 Mussulman. In 1899, 1017 persons were naturalized. From 1865 to 1899, 25,611 were naturalized, of whom 8001 were Italian, 4816 Spanish, 6633 German, and 1315 Anglo-Maltese.

Algeria, in its three departments, contains 17 subordinate prefectures and 348 communes. The important towns are Algiers (96,784 inhabitants), Blidah (27,772), Médéa (16,235), Tizi-Ouzou (27,466), in the department of Algiers; Constantine (51,997), Bône (34,498), Bougie (14,299), Guelma (7288), Philippeville (20,450), Sétif (16,061), in the department of Constantine; Oran (85,081), Mascara (22,203), Mostaganem (17,353), Tlemcen (34,866), in the department of Oran.

Government.—Algeria is administered by a civil governor-general. By decree of 26th August 1881, the budget of the colony was divided among the budgets of the various ministries, and the various services were placed under the direct authority of the respective ministers of France (a system called the *rattachement*), but, after the parliamentary inquiry of 1891, the system was modified, and the decree of 1st January 1897, augmenting the powers of the governor-general, suppressed the *rattachement*, except as regards worship, non-Mussulman justice, public instruction, and the customs. The governor is assisted by a superior council of government, the number of members of which was increased by a decree of 23rd August 1898. Another decree of the same date created the Algerian financial delegations, an elective body representing three categories of taxpayers: (1) the colonists, (2) taxpayers other than colonists, and (3) the natives. The duty of the delegations is to investigate all questions of taxation. Since 1900 Algeria has had a special budget of its own.

Education.—Algiers is the capital of an academic circumscription comprising the whole colony, and is besides the seat of an establishment for superior instruction consisting of faculties of law and of sciences, and a superior school of letters. The total number of students is 786, of whom 300 are students of law. Algeria has three *lycées* (at Algiers, Constantine, and Oran) with 2000 pupils, and nine communal colleges with 3863 pupils, besides a college for girls at Oran with 194 pupils. Most primary schools are Arab-French; the purely Arab are not numerous; some purely French exist. In the year 1897-98 the total number of primary schools was 1168, of which 489 were in the department of Algiers, 347 in that of Constantine, and 332 in that of Oran. The total number of pupils in the schools was 108,000, of whom 65,000 were boys and 43,000 girls. In the year 1897-98 the number of children at infant schools was 29,000. There are three superior Mussulman schools at Algiers, Tlemcen, and Constantine, where pupils are prepared for native employments.

Justice.—Justice is administered in the last resort by a court of appeal sitting at Algiers. There are sixteen tribunals of arrondissements or tribunals of first instance, besides tribunals of commerce

and justices of the peace with extensive jurisdiction. Criminal justice is organized as in France. In 1897, 470 criminal charges were laid, resulting in 439 convictions; 71,210 persons were accused of minor offences and 21,228 of misdemeanours. In the penal establishments there were registered 50,223 entrances, of which 797 were for long terms of imprisonment and 49,426 (including 1416 women) were for shorter terms. Concurrently with the French there is a Mussulman system of justice for the decision of suits between natives. It is administered in the first instance by the *cadis*, whose sentences, on appeal, are within the jurisdiction of French courts.

Finance.—The increase of the expenditure is shown by the following budget estimates for 1880, 1890, and 1899 (25 francs = £1):—

Years.	Expenditure.
1880	£4,040,000
1890	4,920,000
1899	5,100,000

In 1899 the civil expenditure amounted to £2,920,000, the military to £2,080,000, and the pensions to £100,000. The receipts for 1899 were put at £2,166,000, of which £1,584,000 was from taxation, £218,000 from monopolies, and £178,000 from customs. The expenditure thus exceeded the receipts by £2,934,000, the deficit being met by the French Treasury, which besides providing for the military outlay contributes £860,000 towards the civil expenditure. But for a proper estimate of the cost of Algeria to France, besides the sums paid to the state as contributions to the public service, those paid to the departments and to the communes, amounting to about £1,600,000 annually, must be taken into account. Altogether Algeria spends about £6,680,000, towards which it contributes only £3,760,000.

Army.—The army constitutes the nineteenth French army corps. Its three divisions are at Algiers, Oran, and Constantine respectively, and contain a total strength of 60,800 rank and file. The elements of the divisions are the Zouaves (13,670), Algerian Rifles (15,249), the foreign legion (10,759), the African light infantry (8253), the African chasseurs (5314), and the Spahis (3532).

Agriculture.—By far the most important of the resources of the colony is agriculture, on which on 1st January 1898, 3,644,614 persons were estimated to be dependent, 207,310 being Europeans. At the same date the area cultivated was estimated at 26,182,000 acres, of which 7,647,100 acres were under wheat and other cereals (1,188,100 acres belonging to Europeans, and 6,459,000 acres to natives). In 1880 the area under cereals did not exceed 7,768,000 acres. The crops of wheat, barley, and oats yielded respectively 12, 16, and 1·2 millions of cwt. in 1880, and 14·6, 18, and 1·6 in 1898. In the latter year rye and maize yielded respectively 1,748,000 and 200,000 cwts. The cultivation of the vine, after encountering serious difficulties, has greatly extended. The vineyard area and produce in various years were:—

Years.	Acres.	Gallons.
1872	39,500	4,994,000
1880	55,800	9,504,000
1888	308,750	60,742,000
1898	348,270	100,194,600

The value of the wine-yield in 1898 was not less than £6,600,000 sterling. Of the three departments Oran produced the largest quantity, 40,772,600 gallons; then Algiers, 37,037,000 gallons; and Constantine, 22,385,000 gallons. Tobacco covers 17,330 acres, yielding 106,480 cwt. Early fruits are cultivated with success in the Mitija. There are about 7,000,000 olive-trees, which promise to become a source of wealth. Alfa-grass, an important article of commerce with England, grows on the high plateaus, where about 410,000 tons are annually gathered on an area of about 2,964,000 acres or 4630 square miles.

Forests.—The forests cover an area (chiefly on the mountain slopes) of about 7,410,000 acres, or 11,600 square miles. About 1,235,000 acres are in private ownership, 247,000 acres belong to communes, and the whole of the remainder is the property of the state. The cork-oak extends over an area of 684,000 acres, the zeen-oak and the aleppo pine belong to valuable species. The date-palm is cultivated in the oases; at Biskra there are 150,000 palm-trees; in the Ziban, 556,000; in the Wed Kir, 637,000; in the Souf, 180,000.

Live Stock.—The live stock in 1898 consisted of 202,343 horses, 142,796 mules, 255,870 asses, 205,827 dromedaries, 1,004,175 cattle, 7,026,290 sheep, 3,566,508 goats, and 90,765 pigs; in all, 12,494,574 animals, of which 831,457 belonged to non-natives and 11,663,117 to natives. The value of the agricultural material was estimated at £1,160,000 sterling.

Mines and quarries.—In the department of Algiers are coal-mines yielding about 10,000 tons of coal annually. Iron is mined at Mokta el Hadid, at Ain Mokra, and at other places; the yearly

output being about 470,000 tons, worth £200,000 sterling. In the extraction of the ore about 1500 workpeople are employed. The zinc and lead mines yield about 43,000 tons, worth £55,000 sterling. Antimony is found in the department of Constantine. The phosphate beds recently discovered provide material for a rapidly increasing industry. They yielded 240,000 tons of phosphate in 1899. There are more than 300 quarries of stone, marble, &c. Salt is collected on the margins of the chotts or lakes on the high plateaus.

Industry.—Industries are not very active. The more important are pottery, employing 1520 workmen; shipbuilding, 256; tanning and leather-dressing, 2462; weaving and plaiting esparto goods, 9272; chemical works. In 1898 there were altogether 19,398 industrial establishments, employing 59,077 persons.

Commerce.—The principal imports are living animals, cereals, coffee, timber, coal, and tissues; while the chief exports are wine, alfa, tobacco, iron-ore, hides, cork, phosphates. The general trade (imports and exports) in 1870 amounted to the value of 12 millions sterling; in 1880 to 18.4 millions, in 1889 to 16.4 millions, in 1898 to 23.5 millions. The special trade in 1898 amounted to 11.6 millions sterling for imports and 10.6 millions for exports. The imports from France were of the value of 9 millions sterling, and the exports to France almost reached the same amount. France sends to Algeria tissues, ready-made clothing, furniture, metal goods, leather and leather goods; and receives from Algeria wine, cereals, sheep, wool, and horses. The imports from Great Britain reached the value of £248,000, and the exports to Great Britain £544,000. Other countries trading with Algeria were in 1898 (in order of importance) Morocco, Russia, Tunis, Spain, the United States, Italy, Brazil, and Belgium.

Shipping.—In 1898, 1834 vessels of 1,101,668 tons entered Algerian ports from abroad, and 1798 of 1,117,408 tons cleared for ports outside of Algeria. In the coasting trade, 8627 vessels, aggregating 1,621,623 tons, entered, and the same cleared. Direct shipping relations between Algeria and France are reserved exclusively for the national flag. The most frequented Algerian port is Algiers (1,700,000 tons), then Oran (1,000,000), Philippeville (500,000), and Bona (500,000). On 1st January 1899 the mercantile marine consisted of 657 sailing vessels of 7420 tons, and 64 steamers of 10,958 tons.

Railways.—In 1888 Algeria had 1740 miles of railway; in 1900, 2087 miles, of which 1357 were of normal gauge, besides 1134 miles under construction, of which 160 miles were of normal gauge. The principal lines are those from Algiers to Constantine, 290 miles; from Algiers to Oran, 266 miles; and the lines crossing or penetrating the country from Mostaganem to Am Sefra in the department of Oran, and from Philippeville to Biskra in the department of Constantine. The line from Algiers to Constantine is continued across the Tunisian frontier as far as the city of Tunis. The railway receipts in various years and the receipts per mile were as follows:—

Years.	Total Receipts.	Receipts per Mile.
1870	£94,000	£431
1880	489,600	594
1890	965,840	554
1896	968,000	500
1898	1,040,000	498

The receipts per mile have fallen off since 1880 owing to the construction of new lines.

Roads.—The length of the national roads in 1884 was 1784 miles; in 1888, 1794; in 1898, 1791.

Post-offices.—In 1897 there were 553 post-offices. The post and telegraph receipts in 1883 amounted to £150,600; in 1892 to £164,100; in 1897 to £183,000. The post-office orders issued in 1888 numbered 618,861 and were of the value of £1,364,818; in 1897, 925,498, of the value of £1,602,770. The payments into the post-office savings bank in 1888 amounted to £154,750; in 1897 to £387,940.

Banks.—The movement of coin and notes at the Bank of Algeria, whose head office is at Algiers, amounted in 1897-98 to over 56 millions sterling; that at the office of the Algerian Company to 52 millions; and at the five branches of the *Crédit Lyonnais* to 29½ millions. In 1897 the *Crédit Foncier et Agricole* of Algeria made advances to the amount of over 4 millions sterling.

History.—Since the great insurrection of 1871 there have been two revolts in Algeria, that of El Amri in 1876, and that of Bou Amama in 1881, in southern Oran, which was repressed not without difficulty. Another important event was the annexation of Myab (1882), where the inhabitants, tributary since 1853, had refused to fulfil their engagements. Since 1896 Algeria has suffered from the anti-Jewish agitation, which on several occasions, especially at Algiers, Oran, and Constantine, has led to riot and bloodshed. In consequence of the difficulties raised by this propaganda, there has lately been a constant change in governors (see also ANTI-SEMITISM).

Algiers, capital city and seaport of Algeria, the seat of the government-general, of a court of appeal, and of an archbishop, and station of the 19th Corps d'Armée. Taking into account only the ancient Algiers within the circuit of the city walls to the exclusion of the suburban faubourgs, the population, 48,908 in 1872, had increased to 82,585 in 1891, and reached 96,784 in 1900. The French population, 18,216 in 1872 and 38,041 in 1891, numbered 42,004 in 1900; but this increase was mainly due to the facilities offered for the acquisition of writs of naturalization. The Jews numbered 7857; the Arabs, 23,202; foreigners, 23,721. Including the suburban faubourgs from the Pointe Pescade to Maison Carrée, namely, St Eugène, Hussein Dey, Busarea, El-biar, El-Kouba, to mention only the most important groups of population, the inhabitants of Algiers in 1900 numbered 135,000 against about 66,000 within the same area in 1872. Such a marked growth of population is to be ascribed to the extension of commerce, of shipping, of the public services, and of agriculture. Resting on high hills all covered with gardens, Algiers enjoys a delightful situation, and has become one of the most frequented winter resorts. The old Algiers of narrow and steep streets, crowned by the Citadel, the Kasbah, is distinguished from the new Algiers, on level ground, which has for its principal road the superb Boulevard de la République. The chief public buildings are the Government House (Palais du Gouvernement), the cathedral, the Grand Mosque, the library, and museum. The old walls of Algiers will soon be completely demolished, and in their place will be planted a line of forts which will occupy the edge of Mount Busarea at an elevation of over 1300 feet above the sea. The port of Algiers is to be entirely transformed, the Chamber of Commerce and the Government having taken the necessary measures to push forward the works rapidly. The main object is to do away with the sorry port of Agha. At present, however, a public warehouse has been established in connexion with the loading and unloading of the goods. The jetty to the south of the port has been enlarged, pending the extension of the north jetty. Owing to the improvement already accomplished, Algiers has become one of the most considerable colonial maritime *entrepôts*. The tonnage, which in 1883 did not exceed 314,633, entered and cleared, amounted in 1894 to 924,616, and in 1898 to 1,702,310. In short, Algiers engrosses more than 40 per cent. of the total traffic of Algeria. The merchant ships at the port numbered, in 1898, 250 of 10,348 tons, or 72 per cent. of the total tonnage of the merchant marine of Algeria. The seat of a college, with schools of law, medicine, science, and letters, Algiers in 1898 counted 1069 students of higher instruction—509 in letters, 64 in science, 230 in medicine, and 266 in law. Algiers maintains communication with Marseilles by a quick service of steamers, which run the 497 miles across the Mediterranean in twenty-eight to thirty hours. The journey between Algiers and Paris, from which it is distant 1031 miles, is accomplished in about forty-five hours.

Alhama de Granada, a town in the province of Granada, Spain. Population, 7382. In 1884 five churches, the hospital, the prison, the theatre, and more than a thousand houses were destroyed by an earthquake. Eight hundred persons were buried under the ruins. A new town was built near the old one, mostly by subscriptions raised in the rest of Spain. Strange to say, the baths, situate outside the town, were not much injured.

Aliaga, a town of 17,000 inhabitants in the west-central portion of the province of Nueva Ecija, Luzon, Philippine Islands. It is well situated in the midst of a rich Indian corn, rice, sugar, and tobacco-producing region, and has a comparatively cool and healthful climate. Tagalog is the most important language; Ilocano, Pangango, and Pangasinan are also used.

Alicante, a maritime province in the S.E. of Spain, with an area of 2096 square miles. Population (1897), 451,174. The coast-line has an extent of 107 miles. The roads are not in very good condition. Railways run through the province from Alicante to Madrid, and to Murcia and the south of Spain. The province is divided into 14 districts and 138 parishes. There are, in working condition, 7 mines of iron ore, 2 of lignite, and 2 salt-mines. The salt-mines of Torrevieja employed 561 men, and produced in 1898 93,493 tons of the estimated value of £31,082. The live stock in the province includes 4031 horses, 14,960 mules, 8908 donkeys, 2160 oxen and cows, 52,790 sheep, 19,461 goats, and 6555 pigs. Wheat is grown on 9000 acres, rye, oats, barley, and maize on 59,000, vines on 259,000, olive on 41,250. The births in the province average five to every four deaths. The population does not increase, however, owing to the emigration, mainly to Oran in Algeria. Only the provinces of Almeria and Pontevedra show more emigrants annually than Alicante.

Alicante, a town of Spain, capital of the above province, and a resort in winter for invalids on account of its mild and steady climate. Population in 1897, 49,463. Alicante was more affected than the other Mediterranean ports in 1898 when Spain lost her colonies, after her struggle with the United States, as is shown by the figures of the shipping at the port in 1897 and 1898. In 1897 the return of all the shipping gives 1769 vessels, with 1,475,994 tons, and in 1898, 1660 vessels, with 1,008,937 tons. The coasting trade has been on the increase for several years, and this partly explains how 1250 Spanish vessels, with 836,795 tons, rank in the returns for 1898. The principal exports were wines, valued at £700,000 in 1897, and £800,000 in 1898; lead, valued at £160,000 in 1897, and £150,000 in 1898; almonds, valued at £60,000 in 1897, and £65,000 in 1898; esparto, valued at £10,000 in 1897, and £20,000 in 1898; saffron, valued at £75,000 in 1897, and £40,000 in 1898.

Alice Maud Mary, GRAND-DUCHESS OF HESSE-DARMSTADT (1843-1878), second daughter and third child of Queen Victoria, was born at Buckingham Palace, 25th April 1843. A pretty, delicate-featured child—"cheerful, merry, full of fun and mischief," as her elder sister described her—fond of gymnastics, a good skater, and a devoted rider, she was a general favourite from her earliest days. Her first years were passed without particular incident in the home circle, where the training of their children was a matter of the greatest concern to the Queen and the Prince Consort. Among other things, the royal children were encouraged to visit the poor, and the effect of this training was very noticeable in the later life of Princess Alice. After the marriage of the Princess Royal in 1858, the new responsibilities devolving upon Princess Alice, as the eldest daughter at home, called forth the

higher traits of her character, and brought her into still closer relationship with her parents, and especially with her father. In the summer of 1860, at Windsor Castle, Princess Alice first met her future husband, Prince Louis of Hesse. An attachment quickly sprang up, and on the prince's second visit in November they were formally engaged. In the following year, on the announcement of the contemplated marriage, the House of Commons unanimously voted a dowry of £30,000 and an annuity of £6000 to the princess. In December 1861, while preparations were being made for the marriage, the Prince Consort was struck down with typhoid fever, and died on the 14th. Princess Alice nursed her father during his short illness with the utmost care, and after his death devoted herself to comforting her mother under this terrible blow. Her marriage took place at Osborne, on 1st July 1862. The princess unconsciously wrote her own biography from this period in her constant letters to Queen Victoria, a selection of which were allowed to be printed in 1883. They first appeared in Germany, under the editorship of Doctor Sell; the English edition which followed being edited by Princess Helena (Princess Christian). These letters give a complete picture of the daily life of the duke and duchess, and they also show the intense love of the latter for her husband, her mother, and her native land. She managed to visit England every year, and it was at her special request that when she died her husband laid an English flag upon her coffin.

In the war between Austria and Prussia in 1866, Hesse-Darmstadt was upon the side of the Austrians; Prince Louis accompanied his troops to the front, and was duly appointed by the grand-duke to the command of the Hessian division. This was a time of intense trial to the princess, whose husband and brother-in-law, the crown prince of Prussia, were necessarily fighting upon opposite sides. The duke of Hesse also took part in the principal battles of the Franco-Prussian war, while the duchess was actively engaged in organizing hospitals for the relief of the sick and wounded. The death of the duke's father, Prince Charles of Hesse, on 20th March 1877, was followed by that of the grand-duke on 13th June, and Prince Louis succeeded to the throne as Grand Duke Louis IV. In the summer of 1878 the grand-duke and duchess, with their family, came again to England, and went to Eastbourne, where the duchess remained for some time. She returned to Darmstadt in the autumn, and on 8th November 1878 her daughter, Princess Victoria, was attacked by diphtheria. Three more of her children, as well as her husband, quickly caught the disease, and the youngest, "May," succumbed on the 16th. On 7th December the princess was herself attacked, and, being weakened by nursing and anxiety, had not strength to resist the disease, which proved fatal on 14th December, the seventeenth anniversary of her father's death. In a sermon preached on the day after her death, Canon Duckworth admirably summed up the character of the princess: "Endowed with rich intellectual gifts, and with a force and charm of character which would have made her a conspicuous power in any rank, the princess whom we mourn has passed her brief days in unwearied use of great opportunities." She left one son and four daughters. (G. F. B.)

Aligarh, a city and district of British India, in the Meerut division of the North-West Provinces. The city, also known as Koil, is a station on the East Indian railway, 876 miles from Calcutta. Sir Sayad Ahmad Khan, K.C.S.I., who died in 1898, founded in 1864 the Aligarh Institute and Scientific Society for the translation into the vernacular of western literature; and afterwards the Mahomedan Anglo-Oriental College, under English professors, with an English school attached. In 1896-97 the college had 114

students, and meets with strong support from the enlightened portion of the Mussulman community, whose aim is to raise it to the status of a university, with the power of conferring degrees. Population (1881), 61,730; (1891), 61,485; (1901), 70,127, showing an increase of 14 per cent; the municipal income in 1897-98 was Rs.63,923; the death-rate in 1897 was 40 per thousand. There are three flour-mills, several cotton-presses, and a dairy farm.

The district of ALIGARH is traversed by several railways, and also by the Ganges Canal, which is navigable. The chief trading centre is Hathras. Area, 1952 square miles; population (1891), 1,043,172, being 534 persons per square mile; (1901), 1,203,047, showing an increase of 15 per cent., due to the extension of irrigation. The land revenue and rates are Rs.25,97,223, the incidence of assessment being R.1 : 11 : 4 per acre; the cultivated area in 1896-97 was 889,182 acres, of which 526,667 were irrigated from wells, &c.; the number of police was 2954; there are 78 vernacular schools, with 6979 pupils; the registered death-rate in 1897 was 34 per thousand. There are 12 factories for ginning and pressing cotton, and 182 indigo factories, with an out-turn which is valued at Rs.6,88,000.

Alipur. See CALCUTTA.

Alirajpur, a native state of India, under the Bhopawar agency. It lies in Malwa, near the frontier of Bombay. It has an area of 837 square miles; and a population (1891) of 70,091, being 84 persons per square mile. The country is hilly, and many of the inhabitants are aboriginal Bhils. It has from time to time been under British administration. The chief, whose title is Rana, is a Rahtor Rajput. He has an estimated revenue of Rs.130,633 and pays a tribute of Rs.11,000. The town of Alirajpur is situated in 22° 11' N. lat. and 74° 24' E. long. The Victoria bridge was built to commemorate the Diamond Jubilee of 1897.

Alison, Sir Archibald, BART. (1826—), G.C.B., British general and colonel of the Seaforth Highlanders, eldest son of the first baronet, the well-known historian, was born at Edinburgh, on 21st January 1826. Educated at Glasgow and Edinburgh Universities, he entered the 72nd Highlanders as ensign in 1846. He was promoted captain in 1853, and served in the Crimean campaign at the siege of Sebastopol (medal with clasp, Turkish medal, brevet majority). During the Indian Mutiny he was military secretary to Sir Colin Campbell, commander-in-chief, and was severely wounded at the relief of Lucknow, losing an arm (medal with clasp, brevet lieutenant-colonelcy, C.B.). From 1862 to 1873 he served on the staff as an assistant adjutant-general at headquarters, Portsmouth, and Aldershot. He commanded the European brigade, and was second in command of the Ashanti Expedition 1873-74, distinguishing himself at the battle of Amoafu, capture of Bequah, action of Ordahsu, and capture of Kumassi (medal with clasp, thanks of parliament, and K.C.B.). For three years Alison was deputy adjutant-general on the headquarters staff in Ireland and then, for a few months, commandant of the Staff College. He was promoted to be major-general in 1877, and from 1878 to 1882 was head of the intelligence branch of the War Office. He commanded the troops at Alexandria in 1882 until the arrival of Sir Garnet Wolseley, commanded the Highland Brigade at the battle of Tel-el-Kebir in the Egyptian campaign, and remained in command of the army of occupation of Egypt until 1883 (medal with clasp, bronze star, second class Osmanieh, thanks of parliament, and promoted lieutenant-general for distinguished service). He commanded the Aldershot division from 1883 to 1888, was for some

months adjutant-general to the forces during Lord Wolseley's absence in Egypt, was made G.C.B. in 1887, and was promoted general and became a military member of the Council of India in 1889.

Alliù-amba. See ABYSSINIA.

Aliwal, a village of British India, in the Ludhiana district of the Punjab, situated in 30° 57' N. lat. and 75° 37' E. long., on the left bank of the Sutlej. Here, on 28th June 1846, Sir Harry Smith, in command of a cavalry force, inflicted a severe defeat upon the Sikhs.

Aliwal North, a town of Cape Colony, on the left bank of the Orange river, which is here spanned by a fine railway bridge, 860 feet long. It is the present terminus of the line running from East London through Molteno and Burghersdorp northwards, and carries on a brisk trade with the Orange River Colony and surrounding districts. The population is about 3000. Aliwal North is so named to distinguish it from ALI WAL SOUTH, which is the seaport of the pastoral Grasveld district, and stands on the west side of Mossel Bay under the Cape St Blaize headland, by which it is sheltered from the fierce southern winds. It has a considerable import and export trade, ranking in this respect fourth amongst the seaports of Cape Colony. The population is about 3000.

Alkmaar, a town of the Netherlands in the province of North Holland, about 20 miles N.N.W. of Amsterdam by rail. It is also connected by steam tramway (1896) with Purmerend, Amsterdam, and Hoorn. There is a military school here. Population in 1870, 11,410; in 1900, 18,275.

Allada. See DAHOMEY.

Allahabad, a city of British India, the capital of the North-West Provinces, also a district and a division. The city is situated at the confluence of the Ganges and the Jumna, 564 miles from Calcutta by rail. Modern buildings include Government House, the High Court, the Mayo memorial and town hall, the Muir Central College, the Thornhill and Mayne memorial library and museum, the Naini central jail, Trinity church, and the Roman Catholic cathedral. The Jumna is crossed by a railway bridge, and there are two bridges of boats over the Ganges. The military cantonments contain accommodation for all three arms. Population (1881), 148,547; (1891), 175,246; (1901), 175,748. The municipal income in 1897-98 was Rs.3,93,283; the registered death-rate in 1897 was 36.5 per thousand. The municipality consists of 28 members, of whom 21 are elected, with the magistrate as *ex officio* chairman. The water-supply, which was extended in 1897, provides 1,425,000 gallons a day, or 8 gallons per head. In 1896-97 the Muir Central College had 195 students; the Kayasth Pathsala had 73 students. There are four high schools and an American mission. There are 33 printing presses, 4 English and 4 vernacular newspapers, a literary institute, the Kayasth association, a Mahommedan union, and debating society.

The district of ALLAHABAD is traversed by the East Indian railway and the Great Trunk road. Apart from the city, it contains no town with a population exceeding 5000. Area, 2852 square miles; population (1891), 1,548,737, being 543 persons per square mile; (1901), 1,487,904, showing a decrease of 4 per cent. The land revenue and rates are Rs.19,12,757, the incidence of assessment being R.1 : 5 : 3 per acre; the cultivated area in 1896-97 was 882,887 acres, of which 232,774 were irrigated from wells and tanks; the number of police was 4745; there are 217 vernacular schools, with 5941 pupils; the registered death-rate in 1897 was 45 per thousand. The principal crops are rice, millet, pulse, barley, cotton, opium, and indigo.

There are 23 indigo factories, with an out-turn valued at Rs.1,09,000.

The division of ALLAHABAD has an area of 17,265 square miles. Population (1891), 5,757,121, being 333 persons per square mile; (1901), 5,535,803, showing a decrease of 4 per cent., due to the famine of 1896-97, which was severely felt in this tract. It comprises the eight districts of Cawnpore, Fatehpur, Banda, Hamirpur, Allahabad, Jhausi, Jalaun, and Lalitpur.

Allegheny, a city of Pennsylvania, U.S.A., situated in lat. 40° 27' N. and long. 80° 00' W. on the north bank of the Allegheny and Ohio rivers, opposite Pittsburg, with which it forms a single business and manufacturing community. The elevation above sea-level at the station of the Pennsylvania Railroad, in the lower part of the city, is 736 feet, most of the city being much higher. The main position is on a plateau immediately above the rivers, with residence portions extending over the hills behind. The river part is occupied by manufacturers, while the principal mercantile quarter is along Federal and Ohio streets, which intersect at a central square, containing the city hall, post office, Carnegie free library, and the marketplace. The parks consist of the east, north, and west parks, nearly surrounding the central business section, and Riverview Park on the hills about two miles to the north. The population in 1890 was 105,287; in 1900, 129,896, with a death-rate of 16.23. The higher institutions of learning are the Western University of Pennsylvania and theological seminaries of the Presbyterian and United Presbyterian churches. In the lower part of the city is the Riverside State Penitentiary. The government consists of a mayor, and departments of public safety, public works, and public charity, with select and common councils. The annual expenditure is \$2,099,000, the debt is \$4,810,588, and the valuation of property \$81,601,300. There are three hospitals, ten banking institutions, and four insurance companies. It has extensive manufactures, amounting in 1890 to \$20,500,000, mainly of iron, leather, and paint. Three railways, the Pennsylvania, the Pittsburg and Western, and the Buffalo, Rochester, and Pittsburg, enter the city.

Allenstein, a town of Prussia, province East Prussia, 100 miles by rail N.E. from Thorn. It has a mediæval episcopal castle, a couple of churches, a synagogue, a lunatic asylum, and various industries—iron-foundries, saw-mills, brick-works, and breweries; also a trade in cereals and timber. Population (1885), 11,555; (1895), 21,579; (1901), 24,307.

Allentown, a city of Pennsylvania, U.S.A., the capital of Lehigh county, situated in 40° 37' N. lat. and 75° 27' W. long., in the eastern part of the state, in Lehigh Valley, at an altitude of 256 feet, sixty miles north by west from Philadelphia. Though its site is hilly, its plan is quite regular. The city is divided into eleven wards, and is entered by four railways, the Central of New Jersey, the Lehigh Valley, the Perkiomen, and the Philadelphia and Reading. It has important manufactures of boots and shoes, iron and silk. It is the site of Muhlenburg College. The population in 1880 was 18,063, in 1890 it was 25,228, and in 1900 it was 35,416.

Alleppi, or AULAPALAY, a seaport of Southern India, in the state of Travancore, 33 miles south of Cochin, situated on a strip of coast between the sea and one of those backwaters that here form the chief means of inland communication. There is a lighthouse, 85 feet high, with a revolving white light visible 18 miles out at sea. The exports consist of coffee, pepper, cardamoms, and coconuts. There are two factories for coir matting. The

Raja has a palace, and Protestant missionaries have a church. Population (1891), 22,768.

Aller, a town of Spain, in the province of Oviedo, 21 miles S.E. of Oviedo, on the coast side of the Picos de Europa that separate the basin of the rivers running towards the sea from the dry plateau of Old Castile. It stands in the midst of a wooded country, and in the neighbourhood are coal and iron-ore mines and an iron foundry. There are two churches and schools. Population (1897), 11,975.

Alliance, a city of Stark county, Ohio, U.S.A., situated in the north-east part of the state, at an altitude of 1081 feet, on three lines of railway. It is the seat of Mount Union College. Its manufactures consist in great part of agricultural tools and machines. The population in 1880 was 4636, in 1890 it was 7607, and in 1900 it was 8974.

Allier, a department in the centre of France. It is traversed by the ramifications of the mountains of Dôme and of the Forez, and watered by the Allier and the Cher. Its area occupies 2850 square miles. The department comprises 29 cantons, 321 communes, and had a population in 1901 of 422,083, against 424,582 in 1886. Births (1899), 7999, of which 463 were illegitimate; deaths, 7236; marriages, 3590. The towns are Moulins (22,415 inhabitants in 1896), Gannat, La Palisse, Commentry, Montluçon, and Vichy. In 1896 there were 872 primary schools, with 60,688 pupils, and 9 per cent. of the population was illiterate. The area under cultivation measured 1,660,255 acres, of which 1,185,600 acres were in forest and 34,580 acres in vineyards. In 1899 the wheat crop yielded a value of £1,804,210, and the vines £200,000. The live stock (1899) numbered 742,510 head, of which 275,900 were cattle. Allier counts among the departments of France in which the mining industry is in a forward state. It produces a million tons of coal yearly in the basin of Commentry. The industry in metals has likewise assumed large proportions around Montluçon, turning out 69,000 tons of iron, cast-iron, and steel, of the value of £700,000, in 1898. The other industries are in glass, in paper, in chemical products (Commentry), and in cutlery (St Pourçain).

Allingham, William (1824-1889), Irish man of letters and poet, was born at Ballyshannon, Donegal, 19th March 1824 (or 1828, according to some authorities), and was the son of the manager of a local bank. He obtained a post in the custom-house of his native town and filled several similar situations in Ireland and England until 1864, when he became sub-editor of *Fraser's Magazine*, which he subsequently edited until 1879. He had made himself known by the publication of a volume of poems in 1850, followed by *The Music Master and Day and Night Songs*, a volume containing many charming lyrics, in 1855, and by *Lawrence Bloomfield*, a narrative poem illustrative of Irish social questions, in 1864. He married Helen Paterson, known under her wedded name as a distinguished water-colour painter, and died at Hampstead on the 18th of November 1889. Though working on an unostentatious scale, Allingham produced much excellent lyrical and descriptive poetry, and the best of his pieces are thoroughly national in spirit and local colouring.

Allman, George James (1812-1898), British biologist, was born in Cork, Ireland, in 1812, and received his early education at the Academical Institution, Belfast. For some time he studied for the Irish bar, but ultimately gave up law in favour of natural science. In 1844 he graduated in medicine at Dublin, and was at once appointed Professor of Botany in that university. This position he held for about twelve years until he removed to Edinburgh as Regius Professor of Natural History.

There he remained till 1870, when considerations of health induced him to resign his professorship and retire to Dorsetshire, where he devoted himself to his favourite pastime of horticulture. The scientific papers which came from his pen are very numerous. His most important work was upon the gymnoblastic hydrozoa, on which he published in 1871-72, through the Ray Society, an exhaustive monograph, based largely on his own researches and illustrated with drawings of remarkable excellence from his own hand. Biological science is also indebted to him for several convenient terms which have come into daily use, e.g., *endoderm* and *ectoderm* for the two cellular layers of the body-wall in Coelenterates. He became a Fellow of the Royal Society in 1854, and received a Royal medal in 1873. For several years he occupied the presidential chair of the Linnæan Society, and in 1879 he presided over the Sheffield meeting of the British Association. He died 24th November 1898.

Alloa, a river port and police burgh on the north side of the Forth in the county of Clackmannan, Scotland, 28 miles from Leith by water, and 6½ miles E. of Stirling by rail. The register of shipping included 7 vessels of 374 tons at the end of 1898; in 1898 entered 918 vessels of 177,004 tons, cleared 1056 of 201,576 tons. Coal is the chief article of export, 345,631 tons being shipped in 1898. There are in the town 8 breweries. Spinning mills (its yarn is famous), engineering works, and chemical works are among the industrial features. The parish church has been restored internally, and recent erections are a hall and museum, a town hall and free public library (designed by Mr. Waterhouse, R.A., the gift of Mr. J. Thomson Paton), a county combination hospital, a secondary school, public baths and gymnasium, and an accident hospital. A public park has been opened. One of the schools is an academy. Population of police burgh in 1881, 8812; 1891, 10,754; 1901, 11,417.

Allotments and Small Holdings.—As the meaning of these terms varies in different localities, it may be as well to say at once that for the present purpose they are definable as pieces of land detached from cottages, and hired or owned by labouring men to supplement their main income. We do not include any farm, however small, from which the occupier derives his main support by dairying, market-gardening, or other form of *la petite culture*. So, also, no account is taken of the tiny garden plot, used for growing vegetables for the table and simple flowers, which is properly an appurtenance of the cottage. Clearing away what is extraneous, the essential point round which much controversy has raged is the labourer's share in the land. To some extent this depends upon tradition. In agriculture, the oldest of all industries, a cash payment is not even now regarded as discharging the obligations between master and servant. Mr. Wilson Fox, in reporting to the Board of Trade on the earnings of agricultural labourers in Great Britain, gives, as a typical survival of an old custom, the case of a shepherd whose total income was calculated at £60 a year, but who got only £16 in money, the rest being made up by rights of grazing live-stock and growing crops on his master's land, and kindred privileges. That is exactly in the spirit that used to pervade agriculture, and doubtless had its origin in the manorial system. If we turn back to the 13th century, from Walter de Henley's *Husbandry* it will be seen that practically there were only two classes engaged in agriculture, and corresponding with them were two kinds of land. There were, on the one hand, the employer, the lord, and his demesne land; on the other, the villans, and the land held in villenage. Putting aside for the moment any discussion of the exact degree of servitude, it

will be seen that the essence of the bargain was that the villan should be permitted to cultivate a virgate of land for his own use in return for service rendered on the home farm. This is not altered by the fact that the conditions approached those of slavery, that the villans were *adscripti glebæ*, that in some cases their wives and sons were bequeathed by deed to the service of religious houses, and that in many other respects their freedom was limited. Out of this, in the course of centuries, was developed the system prevailing to-day. Lammas lands are indeed a survival from it. There are in the valley of the Lea, and close to London, to take one example, lands allotted annually in little strips till the crops are carried, when, the day being fixed by a reeve, the land becomes a common pasture till the spring closing takes place once more. Perhaps the feature of this old system that bears most directly on the question of allotments was the treatment of the waste of the manor. The lord, like his tenants, was limited by custom as regards the number of beasts he could graze on it. After the havoc of the Black Death in 1349, many changes were necessitated by the scarcity and dearness of labour. It became less unusual for land to be let and for money payment to be accepted instead of services. There was a great demand for wool, and to conduct sheep-farming on a large scale necessitated a re-arrangement of the manor and the enclosure of many common fields under the statute of Merton and the statute of Westminster Second. Nevertheless, up to the 18th century, a vast proportion of agricultural land was technically waste on which rights of common were exercised by yeomen, some of whom had acquired holdings by the ordinary methods of purchase or inheritance, while others had merely squatted and built a house on the waste. It is to this period that belongs a certain injustice to which the peasantry were subject. No reasonable doubt can be entertained of the necessity of enclosure. Husbandry, after long stagnation, was making great advance; and among others, Arthur Young raised his voice against the clumsy inconvenient common fields that were the first to be enclosed. Between 1709 and 1797 no fewer than 3110 Acts, affecting, as far as can be calculated, about 3,000,000 acres, were put into operation. They seem mostly to have been directed to the common fields. In the first half of the 19th century the movement went on apace. In a single year, 1801, no fewer than 119 Acts were passed; and between 1801 and 1842 close on 2000 Acts were passed—many of them expressly directed to the enclosure of wastes and commons. The same thing continued till 1869. It touched the peasant directly and indirectly. The enclosure of the common fields proved most hurtful to the small farmer; the enclosure of the waste injured the labourer by depriving him, without adequate compensation, of such useful privileges as the right to graze a cow, a pig, geese, or other small animals. It also discouraged him by tending to the extinction of small tenancies and freeholds that were no longer workable at a profit when common rights ceased to go with them. The industrious labourer could previously nourish a hope of bettering his condition by obtaining a small holding. Yet, though the labourer suffered, impartial study does not show any intentional injustice. He held a very weak position when those interested in a common affixed to the church door a notice that they intended to petition. As Mr Cowper said in the House of Commons on 13th March 1844, "the course adopted had been to compensate the owner of the cottage to whom the common right belonged, forgetting the claims of the occupier by whom they were enjoyed"; and in the same debate Sir Robert Peel pointed out that not only the rights of the tenant, but those of his successors ought to have been studied. The course adopted divorced the labourer from the soil.

Parliament, as a matter of fact, had from a very early period recognized the wisdom of contenting the peasant. In the 14th century England was a land of small farms wherein the tenant lived in rude abundance. Next century a rural exodus began, owing to the practice of enclosing the holdings and turning them into sheep walks. In 1487 an Act was passed enjoining landlords to "keep up houses of husbandry," and attach convenient land to them. Within the next hundred years a number of similar attempts were made to control what we may call the sheep fever of the time. Then we arrive at the reign of Elizabeth and the famous Small Holdings Act passed in 1597—an anticipation of the three-acres-and-a-cow policy advocated towards the end of the 19th century. It required that no person shall "build, convert, or ordain any cottage for habitation or dwelling for persons engaged in husbandry" unless the owner "do assign or lay to the same cottage or building four acres of ground at the least." It also provided against any "inmate or under-sitter" being admitted to what was sacred to one family. This measure was not conceived in the spirit of modern political economy, but it had the effect of staying the rural exodus. It was repealed in 1775 on the ground that it restricted the building of cottages. By that time the modern feeling in favour of allotments had begun to ripen, and it was contended that some compensation should be made to the labourers for depriving them of the advantages of the waste. Up to then the English labouring rustic had been very well off. Food was abundant and cheap, so were clothes and boots; he could graze his cow or pig on the common, and also obtain fuel from it. Now he fell on evil days. Prices rose, wages fell, privileges were lost, and in many cases he had to sell the patch of land the possession of which made all the difference between hardship and comfort. All this was seen plainly enough both by statesmen and private philanthropists. One of the first experiments was described by Sir John Sinclair in a note to the report of a select committee of the House of Commons on waste lands in 1795. About 1772 the lord of the manor of some commonable lands near Tewkesbury had with great success set out 25 acres in allotments for the use of some of the poor. Sir John was very much struck with the result, and so heartily applauded the idea that the committee recommended that any general Enclosure Bill should have a clause in it providing for "the accommodation of land." Sir Thomas Bernard and Mr Wilberforce took an active part in advocating the principle of allotments, on the ground, to summarize their argument in language employed later by a witness before the House of Commons, that "it keeps the cottagers buoyant and makes them industrious." In 1806, at the suggestion of the rector, a clause assigning an allotment of half an acre to every cottage was inserted in an Enclosure Bill then under consideration for the parish of Broad Somerford in Wiltshire. This was done, "and the example was followed by nearly every adjoining parish in that part of Wiltshire." Passing over several praiseworthy establishments of allotments by private persons, we come to 1819, when Parliament passed an Act akin in spirit to several that came into existence during the later portion of the Victorian era. It empowered the churchwardens and overseers of any parish, with the consent of the vestry, to purchase or hire land not exceeding 25 acres, and to let it in portions to "any poor and industrious inhabitant of the parish." This was amended in 1831 by an Act extending the quantity of land to 50 acres, and also conveying an important new power to enable the same authorities to enclose from any waste or common land not exceeding 50 acres to be devoted to the same purpose. This was followed next year by an Act relating to fuel, and in 1834 the Poor Law Commissioners reported favour-

ably on the principle of granting allotments. In 1843 an important inquiry into the subject was made by a committee of the House of Commons, which produced a number of valuable suggestions. One consequence was the Bill of 1845, brought into Parliament by Mr Cowper. It passed the House of Commons; and there Mr Bright made a remark that probably summarized a general opinion, since it never came to a third reading in the House of Lords. He said that "the voluntary system of arrangement would do all the good that was expected to accrue from the allotment system."

At this point in the history of the movement it may be as well to pause and ask what was the net result of so much legislation and benevolent action. Messrs Tremehere and Tufnall, who prefixed an admirable epitome of what had been done to the report of the Commission "appointed to inquire into the employment of women, young persons, and children in agriculture" (1867), expressed considerable disappointment. Between 1710 and 1867, 7,660,413 statute acres were added to the cultivated area of England and Wales, or about one-third of the area in cultivation at the latter date; and of this total, 484,893 acres were enclosed between 1845 and 1867. Of the latter, only 2119 acres were assigned as public allotments for gardens to the labouring poor. It was found to be the case, as it is now, that land was taken up more readily when offered privately and voluntarily than when it came through official sources. Meanwhile competent and thoughtful men saw well that the sullen discontent of the peasantry continued, in Lord Bacon's phrase, to threaten "the might and manhood of the kingdom." It had existed since the beginning of the Napoleonic wars, and had become more articulate with the spread of education. We shall see a consciousness of its presence reflected in the minds of statesmen and politicians as we briefly examine the later phase of the movement. This found expression in the clauses against enclosure introduced by Lord Beaconsfield in 1876, and gave force to the three-acres-and-a-cow agitation, of which the more prominent leaders were Mr Joseph Arch and Mr Jesse Collings. In 1882 the Allotments Extension Act was passed, the object of which was to let the parishioners have charity land in allotments, provided it or the revenue from it was not used for apprenticeship, ecclesiastical, or educational purposes. A committee of the House of Commons, appointed in 1885 to inquire into the housing of the working classes, reported strongly in favour of allotments, and this was followed in 1887 by the Allotments Act—the first measure in which the principle of compulsory acquisition was admitted in regard to other than charity lands. Its administration was first given to the Sanitary Authority, but passed to the District Councils when these bodies were established in 1894. The local body is empowered to hire or purchase suitable land, and if they do not find any in the market they are to petition the County Council, which after due inquiry may issue a provisional order compelling owners to sell land, and the Local Government Board may introduce a Bill into Parliament to confirm the order. It was found that the Sanitary Authority did not carry out the scheme, and in 1890 another Act was passed for the purpose of allowing applicants for allotments, when the Sanitary Authority failed to provide land, to appeal to the County Council. Judging from the evidence laid before the commission on agricultural depression (1894), the Act of 1887 has not been a conspicuous success. Most of the witnesses reported in such terms as these—"the Allotments Act has been quite inoperative in Cornwall"; "the Act has been a dead letter in the district (Wigtownshire)"; "the Allotments Act has not been in operation in Flintshire"; "nothing has been done in the district of

Pembrokeshire under the Act." No evidence whatever was adduced to show that in a single district a different state of things had to be recorded. From a return presented by the Local Government Board to Parliament in 1896 we learn that eighty-three rural sanitary authorities had acquired land for allotment prior to the 28th December 1894, the date at which these authorities ceased to exist under the provisions of the Local Government Act 1894. Land was acquired by compulsory purchase in only one parish; by purchase or agreement in eighteen parishes; by hire by agreement in 132 parishes. The total acreage dealt with was 1836 acres 1 rood 34 poles, and the total number of tenants 4711. The number of County Councils that up to the same date had acquired land was twelve, and they had done so by compulsory purchase in one parish, by purchase or agreement in five parishes, by hire by agreement in twenty-four parishes. The total area dealt with was only 413 acres 1 rood 5 poles, and the total number of tenants 825. The complete totals affected at the date of the return, 21st August 1895, by the Acts, therefore, were 2249 acres 2 roods 39 poles, and 5536 tenants. A considerable extension has taken place since, but before dealing with that point a word should be said of a measure closely akin to the allotments legislation—viz., the Small Holdings Act introduced by Mr Henry Chaplin, and passed by Parliament in 1892. It was an attempt to appease the rural discontent that had been seething for some time past and was silently but most eloquently expressed in a steady migration from the villages.

The object of this measure was to help the deserving labouring man to acquire a small holding, that is to say, a portion of land not less than one acre or more than fifty acres in extent and of an annual value not exceeding £50. It is not necessary here to describe the legal steps by which this was to be accomplished. The essence of the bargain was that a fifth of the purchase money should be paid down, and the remainder in half-yearly instalments spread over a period not exceeding fifty years. But if the local authority thought fit a portion of the purchase money, not exceeding one-fourth, might remain unpaid, and be secured by a perpetual rent charge upon the holding. It cannot be said that this Act has attained the object for which it was drawn up. From a return made to the House of Commons in February 1898 we obtain a statement of the working of the Allotments and Small Holdings Acts between the 27th December 1894 and the 24th of June 1897. Of this document the following is a summary.

Land was acquired for allotments between the 27th December 1894 and 24th of June 1897 by—

- 3 county councils: (a) in two cases by purchase by agreement, the land handed to parish councils to manage; (b) in one case hiring by agreement. Total acreage, 33 acres 38 poles—let to forty-five tenants.
- 3 councils of county boroughs: one case of purchase, three of hiring by agreement. Total acreage, 42 acres 2 roods 23 poles—let to 171 tenants.
- 120 urban district councils: (a) in 17 cases purchase by agreement; (b) in 118 cases hiring by agreement. Total acreage, 1591 acres 2 roods 4 poles—let to 6644 tenants.
- 9 rural district councils: four cases by purchase, seven by hire. Total acreage, 160 acres 2 roods 18 poles—let to 288 tenants.
- 1009 parish councils: (a) in six cases by compulsory hiring; (b) in 1022 cases by hiring by agreement. Total acreage, 12,967 acres 2 roods 24 poles—let to 24,389 tenants.
- 4 parish meetings: by hiring by agreement. Total acreage, 19 acres 17 poles—let to 47 tenants.

1 metropolitan vestry: by hiring by agreement. 4 acres 2 roods 12 poles—let to 79 tenants.

In this period, therefore, local authorities have acquired for allotment 14,818 acres—let to 31,663 tenants; but 61 county councils, 61 councils of county boroughs, 963 urban district councils, 692 rural district councils, 6361 parish councils, and 5733 parish meetings had not acquired land for allotment.

These facts are not highly encouraging to those who would wish to see every workman in possession of an allotment; but the results of the Small Holdings Act are trivial in comparison. Within the same period only three county councils had acquired land in six parishes for small holdings; in one it was by purchase, in the other five by hire, and the total acreage amounted to only 120 acres 3 roods 5 poles—let to 45 tenants.

It is, however, an English characteristic to prefer private to public arrangements, and probably a very great majority of the allotments now being cultivated are due to individual initiative. There are no means of arriving at the actual facts, but data exist whereby it is at least possible to form some rough idea of them. It is not the custom to give in the annual agricultural returns any statement of the manner in which land is held, and the latest information is to be found in the returns presented to Parliament in 1895. From these we get the following table, which will enable the reader to compare the numbers of large and small holdings, and understand how land is held:—

	From 1 to 5 Acres.		From 5 to 50 Acres.		Above 50 Acres.	
	No.	Acreage.	No.	Acreage.	No.	Acreage.
England . .	87,055	265,268	170,591	3,238,669	122,533	21,290,751
Wales . . .	10,783	35,633	30,969	635,024	18,556	2,167,702
Scotland . .	20,150	65,891	33,921	606,930	25,568	4,219,645
Great Britain .	117,968	366,792	235,481	4,582,623	166,657	27,678,098

It would appear from this that, whereas 27½ million acres are held in large holdings, scarcely five million acres are in small holdings. The proportion varies greatly according to the district. Some counties, such as Cheshire and Worcester, are rich in small holdings; while others—Westmoreland and Devonshire, for example—contain few. We may assume, however, that the allotments do not come into the table at all. They are separately tabulated as holdings of land not exceeding an acre in extent. They may be summarized as follows:—

	Under 1 Acre.	Of 1 Acre.	Total of 1 Acre and over.
England . . .	522,163	34,459	556,622
Wales	12,179	1,095	13,274
Scotland . . .	7,648	1,589	9,237
Great Britain	541,990	37,143	579,133

These figures are useful, but they should be taken as only approximate. It is in the nature of the case that there should be much fluctuation in the number of these tiny plots, movement of population and other causes frequently leading to whole nests of them being deserted by the original occupiers and turned into ordinary fields again. A large proportion of them are held by persons not engaged in agriculture, but following other pursuits: witness the fact that they are most numerous in proportion to every 1000 acres cultivated in Nottingham, Northampton, and Leicester. Very often an allotment is more acceptable to a village tradesman, a carpenter, bootmaker, or miner, than to a farm-servant. Work on it to the

latter represents only a continuation of the day's drudgery, while it is a pleasant change and relief to the former. Further, local conditions have much to do with their popularity. In practice, it is not found that a Northumbrian hind cares much for an allotment. He has a thousand or fifteen hundred yards of potatoes grown with his master's crop, and he gets meal and fuel as part of his wages. Better still, he has a twelve months' engagement for "rain or shine, sickness or health"; but where perquisites are not given on a scale so liberal, and wages are lower and engagements from week to week—even from day to day, as in some of the eastern counties of England,—then naturally the advantages of the allotment are much more highly prized.

Apart from those created by legislation, there are many groups of small agricultural holdings that have either come to exist naturally or have been made during the last few years. Cheshire is a county wherein the former prevail. A typical estate in it is that of Lord Egerton of Tatton. This is divided into 189 holdings, of which 117 are of less than 50 acres and 72 are under 10 acres. Even in a county so notable for its excellent pasture a man could scarcely manage to live on one of these last-mentioned holdings; and, as a matter of fact, those who have them are either agricultural labourers or possess some other means of earning a livelihood; but the land forms a valuable supplement to wages. One point of importance is that nowhere are large healthy families more prized than on these small holdings, where the girls at a very early age learn to look after the poultry and attend to the lighter duties, while boys are set to harder tasks. It has been observed that in portions of England where farm labour is badly paid, and the men have no land, children are regarded as burdens and misfortunes. The Peckforton estate of Lord Tollemache differs from that of Lord Egerton, inasmuch as pains have been taken to make small holdings on it. There are over 250 cottages, to which as much land is attached as enables the occupier to keep a cow, and the sale of milk and butter brings in enough to pay the rent and vastly improve the food supply of the cottage. As there are over 120,000 holdings of less than 50 acres in Cheshire, it will be understood that the estates mentioned are typical of others. The Isle of Axholm, in Lincolnshire, has long been famous for its small holdings, and as they are to a great extent cultivated on the open-field system they are probably of great antiquity. In the parish of Epworth there are 421 agricultural holdings, of which 356 are under and 65 over 20 acres in extent; in the parish of Haxey, 574 agricultural holdings, 475 under and 99 over 20 acres; in West Butterwick, 132 agricultural holdings, 109 under 20 acres and 23 over. It would appear that the tendency is towards subdivision. Most of the land is held in strips, and at the owner's death these are often sold separately. During the worst of the depression a great amount of suffering was felt, but recently accounts have been more cheerful. Lord Savile's estate in Yorkshire is an outstanding example of land in small holdings. It consists of 10,848 acres, held in 682 tenancies, averaging about 16 acres each. Experience there seems to show that a man requires about 30 acres of ordinary agricultural land in order to obtain a living from it.

To these examples of small holdings, it may be useful to add an account of the manner in which one set was formed; and we select for the purpose that at Winterslow, in Wiltshire, chiefly for the reason that, save for a little guidance, the men worked out their own salvation. Major Poore, who originally conceived the idea, has not been a penny out of pocket on account of it. When land was cheap in 1892, owing to the depression in agriculture, he purchased an estate. The price came to an average of

£10 an acre, and he made the average for selling it out again £15 on a principle of instalments. But his object was not to make any profit from the transaction, and he formed what is termed a Landholders' Court, formed of the men themselves, every ten choosing one to represent them. This court was found to act well. It collected the instalments, which are paid in advance; and of course the members of it, down to the minutest detail, knew not only the circumstances, but the character of every applicant for land. The result speaks for itself. Early in 1901 there were no arrears, and the expenses having proved only trivial there was a balance of £666 in favour of the court, and about £150 had been spent in sinking a well. This fund has the very great advantage of establishing a common interest in the holders and inducing them to stick together. Various sums have been lent out on mortgage, and, were a neighbouring village to wish it, the Winterslow holders are prepared to listen to an application for a loan. It should be added that all the owners are, in the true sense of the word, peasants. They do not depend on the land for a living, but work in various callings—many being woodmen—for wages that average about 15s. a week. The holdings vary in size from less than an acre to ten acres, and are technically held on a lease of 999 years, practically freehold, though by the adoption of a leasehold form a saving was effected in the cost of transfer. On the holdings most of the men have erected houses, using for the purpose chalk dug up from their gardens, it lying only a few inches below the surface. It is not rock, but soft chalk, so that they are practically mud walls; but being as a rule at least 18 inches thick, the houses are very cool in summer and warm in winter. Major Poore calculates that in seven years these poor people—there are not thirty of them altogether—have managed to produce for their houses and land a gross sum of not less than £5000. This he attributes to the loyal manner in which even distant members of the family have helped.

It remains to give a brief outline of what small holdings are like outside Great Britain. From the results of the Belgian Agricultural Inquiry of 1895 the following table has been compiled, assuming that one hectare=2½ acres:—

Size of Holding.	Occupied by Owner.		Occupied by Tenant.		Total.
	Whole.	More than half.	More than half.	Whole.	
	No.	No.	No.	No.	No.
1½ acres and under . . .	109,169	8,759	34,779	805,418	468,120
1½ " " 5 acres . . .	27,895	19,544	58,929	70,465	176,228
5 " " 10 " " . . .	12,089	18,878	30,340	25,006	81,908
10 " " 50 " " . . .	16,690	18,909	38,443	28,887	97,429
50 or 100 acres . . .	2,021	1,497	8,315	4,517	11,850
Over 100 " . . .	908	470	1,417	2,895	5,185
Total . . .	168,267	68,052	162,128	486,188	829,625

It will be seen from this table that Belgium is pre-eminently a country of small holdings, more than half of the total number being under 50 acres in extent. Of course it is largely a country of market gardens; but as the holdings are most numerous in Brabant, East and West Flanders, and Hainault, the provinces showing the largest number of milch cows, it would seem that dairying and *la petite culture* go together.

In Germany, the number of small holdings is proportionately much larger than in Great Britain. The returns collected in 1895 showed that there were 3,235,169, or 58.22 per cent. of the total number of holdings under 5 acres in area; and of these no fewer than 11 per cent. are held by servants as part of their wages. A table compiled for the *Journal of the Board of Agriculture*

enables us to compare the other holdings with those of Great Britain :—

Size of Holdings.	Germany.		Great Britain.	
	Number.	Per cent.	Number.	Per cent.
5 to 50 acres	2,014,940	86·8	235,481	58·6
50 to 500 „	292,982	12·6	161,438	40·1
Over 500 „	13,809	0·6	5,219	1·3
Total . . .	2,321,731	100	402,138	100

Great Britain, it will be seen, has over 40 per cent. of large farms of between 50 and 500 acres as compared with Germany's 12·6, while the latter has 86·8 of small holdings, compared with England's 58·6.

France also has a far larger proportion of small holdings than Great Britain; its cultivated area of 85,759,000 acres being divided into 5,618,000 separate holdings, of which the size averages a little over 15 acres as against 63 in Great Britain. Of the whole number, 4,190,795 are farmed by the owners, 934,338 are in métayage, and 1,078,184 by tenants. The leading feature is the peasant proprietary. Half of the arable, more than half of the pasture, six-sevenths of the vineyards, and two-thirds of the garden lands are farmed by their owners. Comparison with Great Britain is difficult; but it would appear that, whereas only 11 per cent. of British 520,000 agricultural holdings are farmed by the owners, the proportion in France is 75 per cent. A further point to be noted is that the average agricultural tenancy in France is just one-fourth of what it is in Great Britain, and the average owner-farmed estate only one-sixth.

Those interested in the formation of small holdings in Great Britain will find much to interest them in the history of Danish legislation. British policy for many generations was to preserve demesne land, and there are many devices for insuring that a spendthrift life-owner shall not be able to scatter the family inheritance; but as long ago as 1769 the Danish legislators set an exactly opposite example. They enacted that peasant land should not be incorporated or worked with estate land; it must always remain in the ownership and occupation of peasants. In this spirit all subsequent legislation was conceived, and the allotment law that came into force in October 1899 bears some resemblance to the English Small Holdings Act of 1892. It provides that labourers able to satisfy certain conditions as to character may obtain from the state a loan equal to nine-tenths of the purchase-money of the land they wish to acquire. This land should be from 5 to 7 acres in extent and of medium quality, but the limits are from 2½ to 10½ acres in the case of better or poorer land. The total value should not exceed 4000 kr. (£222). The interest payable on the loan received from the state is 3 per cent. The loan itself is repayable after the first five years by annual instalments of 4 per cent. until half is paid off; the remainder by instalments of 3½ per cent., including interest. Provision is, however, made for cases where the borrower desired to pay off the loan in larger sums. Regulations are laid down regarding the transfer of such properties and also their testamentary disposition. The Treasury was empowered to devote a sum of 2,000,000 kroners (£111,000) to this purpose for five years; after that the land is subject to revision.

Even before this law was passed Denmark was a country of small holdings, the peasant farms amounting to 66 per cent. of the whole, and the number is bound to increase, since the incorporation of farms is illegal, while there is no obstacle to their division. Between 1835 and 1885, the number of small holdings of less than one tön-dekarthorn increased from 24,800 to 92,856. What gives

point to these remarks is, that Denmark seems in the way to arrest its rural exodus, and was one of the first countries to escape from the agricultural depression due to the extraordinary fall in grain prices.

Alloys.—The derivation of this word is very clear. The old French *alei*, which was retained in the Norman as *allai* or *alait*, comes from *alleium* or *alaium*, the original being probably *ad-ligo* (*alligo*), to bind together. In the modern sense it would be difficult to find a better description of the nature of an alloy than that given by the metallurgist Biringuccio in 1540, who says that an alloy only signifies an intimate association of one metal with another.

From a modern point of view the question immediately arises whether the associations of metallic elements give results which are in any way different from the union of a metal with a non-metal. Though the whole tendency of modern work has been to break down the barrier between metals and non-metals, still in some ways alloys appear to present a special case of union. Metallic vapours are miscible with any other gas, but metals and non-metals do not seem to unite to form a liquid or solid solution. Nor, it should be remembered, do all metals mix and form a solid mass which is uniform in composition. It has been held that there is no non-metallic solvent for a metal which acts without recognizable chemical action, or one from which the pure metal can be obtained by crystallization. Metallic compounds will, however, dissolve readily in metals; thus, cuprous oxide dissolves in metallic copper. Metallic sulphides again will dissolve in metals, e.g., silver sulphide in lead, and lead in sulphide of lead, and the sulphides will crystallize out from the metallic solvent. In this way bismuth sulphide crystallizes from bismuth. The solubility of carbon in iron, and its separation as graphite from the solvent, is a fact of great industrial importance. It is also considered that no isomorphous mixture of a metallic and a non-metallic substance is known. The molecular structure of a metal appears, therefore, to present some differences from that of a non-metal. Metals possess a characteristic property of conducting electricity without an attendant transfer of matter. This is known as metallic conduction. It has been shown that the diffusion of one metal into another can take place in solid metals at comparatively low temperatures, that is, at temperatures which are far below the melting-points, either of the metals undergoing diffusion, or of the alloys which result from their union. In comparatively recent years a large amount of attention has been devoted to the investigation of the properties and constitution of alloys.

In ordinary cases the constituent metals of alloys are united by melting them together and stirring the molten mass. The action is, however, far from being a simple one, as the union is not merely due to the mechanical stirring, but to the fact that the metals dissolved in each other become spread uniformly by true diffusion. In some cases, the constituent metals of an alloy which are miscible when fluid, separate if the fluid mass is allowed to rest, while in other cases partial separation occurs even after the bulk of the mass has become solid. It sometimes happens that metals will unite at temperatures which are far below those required to fuse

Metals and non-metals.

Formation.

them; to the union so effected the term *cementation* is applied. A very interesting observation was made in 1820 by Faraday and Stodart, who, in the course of an investigation on the alloys of iron with other metals, note their failure to produce certain alloys by cementation, but consider it "remarkable" that platinum will unite with steel at a temperature at which the steel is still solid. This early recognition of the fact that alloys can be produced by cementation is very curious, and shows that Faraday and Stodart had observed a creeping molecular action to occur at a temperature below the fusing-point of either platinum or carburized iron. So long ago as 1878 W. Spring showed that under a pressure varying from 13 to 47 tons per square inch, metallic filings will unite into solid masses which under pressure behave like fluids and truly flow through the apertures of the receptacle in which they are compressed. This fact lends support to the view that cohesion is a form of chemical affinity. By compressing, in a finely divided state, 15 parts of bismuth, 8 parts of lead, 4 parts of tin, and 3 parts of cadmium, an alloy is produced which fuses at 100° C. Hallock found that metals might be united without pressure, if they were heated to the melting-point of the alloy to be formed, that is, to a point which as a rule is much below the melting-point of the least fusible constituent.

It has long been known that brass may be formed by electro-deposition from a solution containing copper and zinc. In this connexion J. B. Senderens has made a very interesting series of experiments on the precipitation of one metal from solution by another metal. He points out that Richter in his researches, published between the years 1796-99, was led to the promulgation of the law which is now expressed as follows: "Metals are precipitated from their saline solution atom for atom of the same valency." Senderens shows that this is not rigorously accurate, since the amount of the precipitating metal is always in excess. Thus, in the well-known reaction employed in refineries for the precipitation by copper of silver from sulphate solutions, in accordance with the equation— $\text{AgSO}_4 + \text{Cu} = \text{Ag} + \text{CuSO}_4$, if the solution of sulphate of silver contains 4.5 grammes of the salt in a litre of water, a plate of copper immersed in it for seven days will be found to have lost 0.012 gramme more than theory demands. Senderens shows that this fact is of singular interest in relation to the allotropy of iron, but his work is quoted here on account of its bearing on the formation of alloys in the "wet way." Several chemists, among whom Planché and Brugnatelli may be specially mentioned, have thought that alloys might be so prepared, while Gay-Lussac at first favoured that opinion, but abandoned it later. So long ago as 1857, in a remarkable paper on "The Reciprocal Precipitation of Metals," Odling showed that a piece of copper coated with cadmium, and a coil of copper and cadmium foils rolled up together, behave very differently when treated with hydrochloric acid, the metallic deposit of cadmium partaking of the character of an alloy. Such precipitation of one metal on another he attributes to the affinity of one metal for the other. He in fact formed alloys in the "wet way." More recently Mylius and Fromm have shown that alloys may be precipitated from dilute solutions by zinc, cadmium, tin, lead, and copper. Thus a strip of zinc plunged in a solution of sulphate of silver containing not more than 0.03 gramme of silver in the litre, becomes covered with a flocculent precipitate which is a true alloy of silver and zinc, and in the same way, when copper is precipitated from its sulphate by zinc, the alloy formed is brass. They have also formed certain alloys of definite composition such as AuCd_3 , Cu_2Cd , and, more interesting still, Cu_3Sn . If volatile metals in the form of vapour are brought in contact with non-volatile metals, union will in many cases ensue. It has been shown that alloys of platinum and palladium with cadmium, zinc, and magnesium may be so produced.

In the classical monograph on alloys published by Matthiessen in 1860 (*Phil. Trans. R. S.*), it was clearly stated that alloys must be considered to be solidified solutions. Few generalizations have been more fruitful in results, and much modern work has been devoted to the development of the view. The constitution of solutions has been very closely studied in recent years, and from the point of view of their freezing-points F. Guthrie has shown that solutions of metals in

each other behave like ordinary aqueous solutions of salts. His actual results for solutions of common salt in water are given in Fig. 1.

If, for instance, a thermometer be placed in a 10 per cent. solution of salt in water which is being slowly cooled by means of an external freezing mixture,

the mercury will halt in its fall at about 8° C., owing to the separation of pure salt-free ice. This gives the point *d* on the branch AB. The mercury then continues to fall until the temperature of 22° C. is reached, and the cryo-hydrate or *eutectic* of ice and salt solidifies. This eutectic, as has been abundantly shown, consists merely of a very intimate mixture of ice and salt in juxtaposition. As the degree of concentration of salt in the original solution increases, the initial freezing-point on the branch AB will become lower and lower, while the second freezing-point always remains constant at -22° C.; and when the solution contains 23.5 per cent. of salt, both freezing-points coincide in the point B at -22° C. The salt branch of the diagram is a very steep one, because the melting-point of pure salt is above 700° C. Take on this branch a point *e* representing water containing more salt than 23.5 per cent., say 25 per cent. In this case the first solid to separate on cooling is pure salt, and it does so at -12° C., which, for this degree of concentration is the first halting stage of the thermometer; the second is, as before, the solidification of the eutectic of salt and ice, which always has the same composition, and freezes at the same temperature, namely 22° C. The diagram therefore has two branches joining at B a horizontal line. This curve has been described at some length, because curves representing the freezing-points of any series of alloys may be derived in the same way. Guthrie considered that alloys in cooling behave like a cooling mass of clear molten granite. This would throw off in cooling "atomically definite" bodies, leaving behind a fluid mass not definite in composition, since the quartz and felspar undergo solidification before the mica. In alloys much the same thing happens, for when a molten mass of lead and bismuth, or bismuth and tin, cools, a certain alloy of the metal falls out, just as the quartz and felspar did, and ultimately the most fusible alloy of the series is left. This is called by Guthrie the eutectic alloy, but the proportions between the constituent metals are not atomic, and Guthrie pointed out that "the preconceived notion that the alloy of minimum temperature of fusion must have its constituents in simple atomic proportions, and that it must be a chemical compound, seems to have misled previous investigators"; but he adds "that certain metals may and do unite with one another in the small multiple of their combining weights, may be conceded; the constitution of eutectic alloys is not in the ratio of any simple multiple of their chemical equivalents, but their composition is not on that account less fixed, nor are their properties the less definite." The constitution of eutectic alloys as revealed by the microscope will be dealt with in the article on METALLOGRAPHY.

Mendeléeff regards solutions as strictly definite atomic chemical combinations at temperatures higher than their dissociation temperatures. Definite chemical substances may be either formed or decomposed at temperatures which are higher than those at which dissociation begins; the same phenomenon occurs in solutions. In order to show how close the relation is between freezing solutions of salt in water and in an alloy, no simpler case could well be taken

Fig. 1.

than the lead-tin series given in Fig. 2. It represents, moreover, a series in which the freezing-points are well within range of the ordinary mercurial thermometer, and of which the complete freezing-point curve is exactly of the same order as that which represents the freezing of a solution of salt, as Roberts-Austen has shown. For alloys of which the melting-points are beyond

Fig. 2.

the range of the ordinary mercurial thermometer, some form of pyrometer must be employed. Heycock and Neville, in a very elaborate and prolonged series of investigations on the freezing-point curves of alloys, have used the platinum resistance pyrometer, and they determine the points at which alloys solidify or metallic constituents fall out of solution by noting the points at which the electrical resistance (as measured by a Wheatstone Bridge) remains constant. Roberts-Austen, on the other hand, has devised a recording pyrometer for use with a thermo-junction. This instrument traces automatically on a sensitized plate the cooling curve of any definite alloy, the halting places corresponding to the arrests in the fall of the mercurial column in an ordinary thermometer being indicated by more or less horizontal portions. H. le Chatelier has thrown much light on the question of the fusibility of alloys. He points out that in considering them as solutions it is necessary to modify the view in which ordinary solutions are regarded. In ordinary chemical language, it is usual to distinguish the solvent from the body which is dissolved, but really the two bodies play the same part. Many aqueous solutions, as he shows, can exist below the freezing-point of water: that of chloride of calcium, for instance, which is liquid down to -55°C . He demonstrates that the typical curves which represent the fusibility of alloys have in each case corresponding curves in saline solutions, and in confirmation quotes experiments by Loewel and Bakhuis-Roozeboom, together with his own results, especially referring to the freezing-point curves of isomorphous mixtures of certain organic substances first recorded by Kuster. The result of Le Chatelier's very interesting work is the division of the freezing-point curves of alloys into the following classes:—In the first the metals dissolving each other give neither definite compounds nor isomorphous mixtures. The curves of this class consist of two branches as is shown by the lead-tin curve in Fig. 2, in which composition and temperature are coordinates, and it would appear that when a curve is composed of two branches only it is safe to conclude that after solidification the two isolated metals are simply in juxtaposition. In the second case, the two metals give rise to one or more definite compounds. Here, as in the case of a solution of sulphate of soda in water, one branch of the curve is peculiar and characteristic. If the compound which is formed between the two metals fuses without dissociation, there will be a maximum point in the curve which corresponds to the definite compound, and the curve will be of the form shown by Roberts-Austen's gold-aluminium curve in Fig. 3. H. le Chatelier has found similar curves for the copper-tin alloys. In the case of the aluminium-gold series the maximum point occurs, as Fig. 3 shows, at the alloy AuAl_2 , the freezing-point of which is higher than that

Fig. 3.

of pure gold itself. If the compound formed in the alloy is dissociated, the portion of the curve which marks its presence will be rounded. With regard to the gold-aluminium series, Heycock and Neville have shown that it presents a very complicated case, as not merely one compound (AuAl_2), but several compounds of gold and aluminium are formed. In the third case, the two metals which are dissolved in each other form isomorphous mixtures. In this group the freezing-points of the alloys of the series lie on a straight line, Fig. 4, as do the silver-gold alloys examined by Schertel. This question is very important, and Gautier has given several instances of such isomorphous alloys, among which that of antimony and bismuth may be cited.

Fig. 4.

Metals do not appear to have been studied from the point of view of surfusion until 1880, when A. D. van Riemsdijk showed that gold and silver would both pass below their actual freezing-points without becoming solid. Roberts-Austen pointed out that surfusion might be easily measured in metals and in alloys by the sensitive method of recording pyrometry to which reference has already been made. He also showed that the crossing of curves of solubility which had already been observed by H. le Chatelier and by Dahms in the case of salts could also be measured in the lead-tin alloys (Fig. 2). The investigation of the mutual relations of partially miscible liquids due to Alexejew, Konowalow, and to Duclaux was extended to alloys by Alder Wright. The addition of a third metal will sometimes render the mixture of two other metals homogeneous. Heycock and Neville proved that when one metal is alloyed with a small quantity of some other metal the solidification obeys the law of Raoult. They also showed that the molecule of a metal when in dilute solution often consists of one atom. There are, however, numerous exceptions to this rule. In the case of aluminium dissolved in tin and mercury or bismuth in lead, it is at least probable that the molecules in solution are Al_2 , Hg_2 , and Bi_2 , respectively, while tin in lead appears to form a molecule of the type Sn_4 .

Matthiessen in the paper already referred to showed that the electrical conductivity of all alloys may be represented graphically by three types of curves. Gold and silver alloyed afford an instance of the first of these types, there being a rapid decrease in the conductivity (or increase in the resistance) when either silver is added to gold or gold to silver. The tin-copper alloys are, as regards electrical conductivity, types of the L-shaped curve. There is a rapid diminution of conductivity when tin is added to copper, and at a certain point there is an abrupt bend, and the curve proceeds more or less horizontally. More recent work has, however, shown that there are certain breaks where the definite compounds SnCu_3 and SnCu_4 occur. The conductivities of tin and lead are both low, and the lead-tin series is represented by a straight line connecting the two metals. The conductivity curve of these alloyed metals represents the third type. For the details reference must be made to Matthiessen's memoir. At low temperatures, Dewar and Flemmings have shown that the conductivity of pure metals increases greatly as the temperature is diminished. Gold, in the purification of which elaborate precautions were taken, appears to present a very good instance. On the other hand, the conductivity of alloys does not increase with diminution of temperature in the same manner, and a marked contrast between the behaviour of metals and

Electrical conductivity.

alloys is thus presented. Rayleigh has pointed out that this difference may arise from the heterogeneity of alloys. When a current is passed through an alloy, a series of Peltier effects, proportional to the current, are set up between the particles of the different metals, and these create an opposing electromotive force which is indistinguishable experimentally from a resistance. If the alloy were a true chemical compound the counteracting electromotive force should not occur, and experiments in this direction are much needed. Roberts-Austen has shown that in the case of molten alloys the conduction of electricity is apparently metallic, no transfer of matter attending the passage of the current. A group of bodies may, however, be yet discovered between alloys and electrolytes in which evidence may be found of some gradual change from wholly metallic to electrolytic conduction. Laurie has determined the electromotive force of a series of copper-zinc, copper-tin, and gold-tin alloys, and as the result of his experiments he points to the existence of definite compounds. Explosive alloys have been formed by Deville and Debray in the case of rhodium, iridium, and ruthenium, which evolve heat when they are dissolved in zinc. When the solution of the rhodium-zinc alloy is treated with hydrochloric acid, a residue is left which undergoes a change with explosive violence if it be heated *in vacuo* to 400°. The alloy is then insoluble in "aqua regia." The metals have therefore passed into an insoluble form by a comparatively slight elevation of temperature.

The feature of the period from 1875 to 1901 has been the increased attention which has been devoted to the applications of the rarer metals. Thus nickel, which was formerly used in the manufacture of "German silver" as a substitute for silver, is now widely employed in naval construction, and in the manufacture of steel armour-plate, projectiles, and, when alloyed with copper, the envelopes of bullets. Manganese not only forms with iron several alloys of great interest, but alloyed with copper is used for electrical purposes. Chromium also, in comparatively small quantities, is taking its place as a constituent of steel axles and tyres, and in the manufacture of tool-steel. Vanadium, molybdenum, and titanium may be expected soon to play an important part in the constitution of steel. Titanium is alloyed in small quantities with aluminium for use in naval architecture. The importance is now widely recognized of considering the mechanical properties of alloys in connexion with the freezing-point curves to which reference has already been made, but the subject is a very complicated one, and all that need be said here is that when considered in relation to their melting-points the pure metals are consistently weaker than alloys. The presence in an alloy of a eutectic which solidifies at a much lower temperature than the main mass, implies a great reduction in tenacity, especially if it is to be used above the ordinary temperature as in the case of pipes conveying super-heated steam. It may also be stated that alloys of metals with similar melting-points have higher tenacity when the atomic volumes of the constituent metals differ than when they are nearly the same.

Allport, Sir James Joseph (1811-1892), English railway manager, born 27th February 1811, was a son of William Allport, of Birmingham, and was associated with railways from an early period of his life. In 1843 he became general manager of the Birmingham and Derby railway, and in the following year succeeded to the same position on the Newcastle and Darlington line. Six years later he assumed the charge of the Manchester, Sheffield, and Lincolnshire (now the Great Central) railway, and finally, in 1853, was appointed to the general managership of the Midland railway—an office which he held continuously, with the exception of a few years between 1857 and 1860, until his retirement in 1880, when he became a director. During these twenty-seven years the Midland grew to be one of the most important railway systems in England, partly by the absorption of smaller lines and partly by the construction of two main extensions—on the south to London and on the north to Carlisle—whereby it obtained an independent through-route between the metropolis and the north. In the railway world Sir James Allport was known as a keen tactician and a vigorous fighter, and he should be remembered as the pioneer of cheap and comfortable railway travelling. He was the first to appreciate the importance of the third-class passenger as a source of revenue, and accordingly, in 1872, he inaugurated the policy—subsequently adopted more or less completely by all the railways of Great Britain—of carrying third-class passengers in well-fitted carriages at the uniform rate of one penny a mile on all trains, even the fastest. The diminution in the receipts from second-class passengers, which was one of the results, was regarded by some authorities as a sign of the unwisdom of his action, but to him it appeared a sufficient reason for the abolition of second-class carriages, which therefore disappeared from the Midland system in 1875, the first-class fares being at the same time substantially reduced. This innovation too has been followed by other companies, though not with the same unanimity as attended his earlier reform. He was also the first to introduce the Pullman car on British railways. Allport received the honour of knighthood in 1884. He died in London on 25th April 1892. (H. M. R.)

Almada, a town of Portugal, district Lisbon, on the left bank of the Tagus, immediately opposite Lisbon, with manufactories of cork. It was founded by English crusaders in the reign of Affonso Henriques. Population about 7000.

Almaden, or ALMADEN DEL AZOGUE, a town of Spain, in the province of Ciudad Real, in the Sierra Moreno. In the latter part of the 19th century the Almaden quick-silver mines were leased by the state to the house of Rothschild, whose contract expired in 1900, but who still sell the quicksilver for the Spanish Government. The town has a good hospital, schools, and other buildings. Care is taken to minimize the effects of the fumes on the operatives, whose health is very rapidly and seriously impaired. Hence the custom formerly was to use convicts for the labour in the quicksilver mines. Owing to the deleterious effects of the atmosphere, exemption from military service is granted to men who have been two years employed in the quick-silver mines. The average output of mercury is 10 per cent. on the ore extracted, and, according to official returns, 75 per cent. of the value of the output is clear profit. In 1898 there were 1906 men and 417 lads employed in the mines. The amount of ore extracted was 19,945 tons, from which 1595 tons of quicksilver were drawn, being 46,211 flasks weigh-

"THE ROSES OF HERIOCRABAIUS," BY SIR L. ALMA-TADEMA, R.A.

(Reproduced by permission of Sir John Aird, Bart., M.P.)

ing 55,000 lb. In the Arrayanes sulphurous and lead mines 930 men, 18 women and 35 lads were employed, and 18,962 tons of ore were extracted in 1898. The Almaden concession covers over 490,872 acres; the Arrayanes only 1397 acres. Population, 7388.

Alma-Tadema, Sir Laurence (or **Laurens**), British artist, was born on the 8th of January 1836, at Dronryp, a Friesian village near Leeuwarden, the son of Pieter Tadema, a notary, who died when he was four years old. Alma was the name of his godfather. His mother (d. 1863) was his father's second wife, and was left with a large family. It was designed that he should follow his father's profession; but he had so great a leaning towards art that, after a long struggle between duty and inclination, during which his health broke down, he was sent to Antwerp, where in 1852 he entered the academy under Gustav Wappers, the leader of that romantic movement in Belgian art which was fast obliterating the old classical school of David. Thence he passed to the *atelier* of Henri (soon afterwards to become Baron) Leys. In 1859 he assisted Leys in his frescoes in the hall of the Hôtel de Ville at Antwerp. In the exhibition of his collected works at the Grosvenor Gallery in London in the winter of 1882-83 were two pictures which may be said to mark the beginning and end of his first period. These were a portrait of himself, dated 1852, and "A Bargain," painted in 1860. His first great success was a picture of "The Education of the Children of Clovis" (1861), which was exhibited at Antwerp. In the following year he received his first gold medal at Amsterdam. The "Education of the Children of Clovis" (three young children of Clovis and Clotilde practising the art of hurling the axe in the presence of their widowed mother, who is training them to avenge the murder of their own parent) was one of a series of Merovingian pictures, of which the finest was the "Fredegonda" of 1878 (exhibited in 1880), where the dejected wife or mistress is watching from behind her curtain window the marriage of Chilperic I. with Galeswintha. It is perhaps in this series that we find the painter moved by the deepest feeling and the strongest spirit of romance. One of the most passionate of all is "Fredegonda at the Deathbed of Prætextatus," in which the bishop, who has been stabbed by order of the queen, is cursing her from his dying bed. Another distinct series attempts to reproduce the life of ancient Egypt. One of the first of these was called "Egyptians 3000 Years Ago," and was painted in 1863. A profound depth of pathos is sounded in "The Death of the First-born," painted in 1873. Among his other notable Egyptian pictures are "An Egyptian at his Doorway" (1865), "The Mummy" (1867) (depicting the family of the defunct bringing offerings to a mummy which stands on end at the right of the spectator), "The Chamberlain of Sesostris" (1869), "A Widow" (1873), and "Joseph, Overseer of Pharaoh's Granaries" (1874). On these scenes from Frankish and Egyptian life Alma-Tadema spent great energy and research; but his strongest art-impulse was towards the presentation of the life of ancient Greece and Rome, especially the latter. Amongst the best known of his earlier pictures of scenes from classical times are "Tarquinius Superbus" (1867), "Phidias and the Elgin Marbles" (1868), and "The Pyrrhic Dance" and "The Wine Shop" (1869). "The Pyrrhic Dance," though one of the simplest of his compositions, stands out distinctly from them all by reason of its striking movement. "Phidias and the Elgin Marbles" is the first of those glimpses of the art-life of classical times, of which "Hadrian in England," "The Sculpture Gallery," and "The Picture Gallery" are later examples. "The Wine Shop" is one of his many pictures of historical *genre*, but

marked with a more robust humour than usual. In 1863 Alma-Tadema married a French lady, with whom he lived at Brussels till 1869, when she died, leaving him a widower with two daughters, both of whom have since made reputations—one in art, the other in literature. In 1869 he sent from Brussels to the Royal Academy two pictures, "Un amateur Romain" and "Une danse Pyrrhique," which were followed by three pictures, including "Un Jongleur," in 1870, when he came to London. By this time, besides the distinctions he gained in Holland and Belgium, he had been awarded medals at the Paris Salon of 1864 and the Exposition Universelle of 1867. In 1871 he married an English lady, Miss Laura Epps, who, under her married name, has also won a high reputation as an artist. After his arrival in England Alma-Tadema's career was one of continued success. Amongst the most important of his pictures during this period are—"The Vintage Festival" (1870), "The Picture Gallery" and "The Sculpture Gallery" (1875), "An Audience at Agrippa's" (1876), "The Seasons" (1877), "Sappho" (1881), "The Way to the Temple" (1883), his diploma work, "Hadrian in Britain" (1884), "The Apodyterium" (1886), "The Women of Amphissa" (1877), "The Roses of Heliogabalus" (1888), "An Earthly Paradise" (1891), and "Spring" (1895). Most of his other pictures have been small canvases of exquisite finish, like the "Gold-fish" of 1900. These, as well as all his works, are remarkable for the painting of flowers, textures, and hard reflecting substances, like metals; pottery, and especially marble. He paints with much of the fine execution and brilliant colour of the old Dutch masters. By the human interest with which he imbues all his scenes from ancient life he brings them within the scope of modern feeling, and charms us with gentle sentiment and playful humour. He has also painted some fine portraits, including those of Mr Arthur Balfour, Mr Henschel, Herr Richter the musician, and Dr Joachim. He was knighted on the occasion of Queen Victoria's eighty-first birthday, 1899. He was made an associate of the Royal Academy in 1876, and a Royal Academician in 1879. He is a knight of the order Pour le Mérite of Germany (Arts and Science Division); of Léopold, Belgium; of the Dutch Lion; of St Michael of Bavaria; of the Golden Lion of Nassau; and of the Crown of Prussia. He is an officer of the Legion of Honour, France. He is a member of the Royal Academies of Munich, Berlin, Madrid, and Vienna. He received a gold medal at Berlin in 1872, and a grand medal at Berlin in 1874; a first-class medal at the Paris International Exhibition of 1878, and medals of honour at the Paris Exhibitions of 1889 and 1900. He is a member of the Royal Society of Water-colours. He received letters of denization from the Crown in 1873.

Almendralejo, a town of Spain, province of Badajoz, 27 miles E.S.E. of Badajoz. Population, 11,766. It has doubled in importance since 1880, owing to the fertility of its neighbourhood, the cereals, fruit, and wine produced in which are easily exported by the Merida-Sevilla railway. There are thirty-six factories for the production of brandy. The town is well built, with broad streets, a good theatre, a bull-ring, and many private mansions.

Almeria, a maritime province in the S. of Spain, with an area of 3300 square miles. The Linares-Almeria S. I.—42

railway was completed in 1898, also a line connecting the three provinces of Almeria, Granada, and Jaen, and the three with Madrid. Another line from Baeza to Linares is near completion. The local industries have developed with the growth of the means of communication in the last decade. Manufactures of textiles, chocolate, matches, bricks and chalk, oil and flour mills, foundries, have attained importance. Agricultural interests have received a great impulse in the valleys nearest the sea and on the banks of the Almanzora, Antas, and Aguas. Viticulture has been much developed, chiefly with a view to meet the increasing foreign demand for the fruit; a great number of new plantations have been made to replace the indigenous vines. Esparto grass, oil, cereals, barley, have also been exported in greater proportion than a few years ago. Mining interests have been given a considerable impulse by foreign and native capital. The province contained, in 1898, 210 working mines, covering 4710 acres. Of these 14 were zinc mines, 66 iron, 102 lead, and 21 argentiferous lead. The number of hands employed in 1898 was 6449; a few hundred were engaged in 3 lead and 6 argentiferous lead works. The Sierra Alhamilla railway brought down 50,086 tons of iron ore in 1898. A short railway is being constructed between Calahorsa and Alguip to work ten million tons of fine ore at Alguip. The live stock consisted, according to the latest official statistics, of 1163 horses, 11,983 mules, 16,221 donkeys, 3299 oxen and cows, 128,078 sheep, 30,513 goats, and 15,041 pigs. 50,350 acres were devoted to the culture of wheat, 105,000 acres to other cereals, 6500 acres to vineyards, 5000 acres to olive plantations, and 44,500 acres to pod fruit. The population in 1897 was 344,681, or only 78 to the square mile. Education is still in a backward condition, though some improvement has taken place in the last twenty years. With a higher rate of births than deaths the population has yet not increased, because of the steady flow of emigration, which carries away to French Algeria annually from 2000 to 3000 Almerians.

Almeria, a port of Spain in the above province. Population, 46,806. It has greatly grown in importance, and in 1898, 1130 vessels, with a total tonnage of 638,551, entered, exactly the same number of vessels and tonnage clearing. In 1897, 178 British vessels of 173,133 tons entered and cleared; in 1898, 191 British vessels (only 13 with British cargoes) of 183,125 tons. Imports in 1898 were chiefly coal, 14,430 tons; patent fuel, 4331 tons; timber, cod, steel, and railway bars. In the export trade 143 British vessels cleared for Great Britain and her colonies with 129,973 tons. Exports were 135,000 tons of iron ore, valued at £56,700; 658,530 barrels of grapes, £237,071; 17,300 tons of esparto, £69,200; and 24,000 cases of almonds, oranges, melons, pomegranates. The western pier, recently built, is 1 mile 77 yards in length, and has a depth of 8 fathoms at the end.

Almodovar del Campo, a town of Spain, in the province of Ciudad Real, 18½ miles S.S.W. of Ciudad Real. There are lace and linen factories. Population in 1897, 12,110. It was formerly an Arab fortress, hence its name, meaning a sphere.

Almora, a town and district of British India, in the Kumaun division of the North-West Provinces, situated on a mountain-ridge 5494 feet above the sea. Population (1881), 7390; (1891), 7826; municipal income (1897-98), Rs.10,135. It has a college, called after Sir Henry Ramsay; a government high school, a Christian girls' school, and 4 printing presses.

The district of ALMORA was recently constituted, together with Naini Tal, by a redistribution of the two former districts of Kumaun and the Tarai. It lies among

the mountains of Kumaun, between the upper waters of the Ganges and the Gogra, here called the Kali. Area, 5416 square miles; population (1891), 411,501, the average density being 77 persons per square mile; (1901), 465,876, showing an increase of 13 per cent. The land revenue and rates are Rs.2,65,946; the incidence of assessment being R.0: 12: 5 per acre; the cultivated area in 1896-97 was 239,684 acres, of which 2602 were under tea; the number of police was 58; there are 122 vernacular schools, with 4080 pupils; the death-rate in 1897 was 24 per thousand. The district includes the military sanatorium of Ranikhet. The nearest railway *via* Naini Tal is the extension of the Oudh and Rohilkhand line from near Bareilly to Kathgodam.

Alnwick, a market-town, under an urban district council, and the county town of Northumberland, England, in the Berwick-upon-Tweed parliamentary division of the county, on the Aln, 34 miles N. by W. of Newcastle by rail. By prescription, Alnwick is a borough, and its freemen form a body corporate. This body has no authority over the affairs of the town, but, by the Alnwick Corporation Act, 1882, it is required to expend, out of corporate property, not less than £500 a year in payment of teachers' salaries, &c. in connexion with the corporation schools. The peculiar ceremonies long observed in the initiation of freemen are now discontinued. Area 4777 acres; population (1881), 6693; (1891), 6746; (1901), 6716. Area of parish, 16,985 acres; population (1881), 7440; (1891), 7428; (1901), 7385.

Alora, a town of Spain, in the province of Malaga, 17 miles W.N.W. of Malaga, on a spur of mountains commanding a fertile plain where maize, sugar-cane, and palms are grown. There are distilleries, Arab ruins of some importance, and sulphurous springs, and the town is a favourite summer resort for wealthy families from Malaga. Population (1897), 10,308.

Alost (Flemish *Aelst*), a town of Belgium, on the eastern frontier of the province of East Flanders, on the river Dender, 17 miles S.E. of Ghent by rail. Jute yarns and tissues are manufactured. Population (communal) (1880), 20,679; (1890), 25,544; (1897) 28,771.

Alpena, a city of Michigan, U.S.A., the capital of Alpena county, situated on the eastern side of the lower peninsula, on Thunder Bay, an arm of Lake Huron, at an altitude of 607 feet. Its excellent harbour attracts much lake commerce. It is entered by the Detroit and Mackinaw railway. Its industries consist mainly in the manufacture of lumber, shingles, and laths. The population in 1880 was 6153, in 1890 it was 11,283, and in 1900 it was 11,802.

Alpes, Basses, a department in the S.E. of France, traversed by the Alps of Provence, and watered by the Var, the Durance, and its affluents, the Buech, the Ubaye, the Bléonne, and the Verdon. Area, 2699 square miles, distributed among 30 cantons and 250 communes. The population fell from 129,494 in 1886 to 112,763 in 1901. The inhabitants readily emigrate to America, more particularly to Mexico. Births in 1899, 2441, of which 63 were illegitimate; deaths, 2537; marriages, 797. The chief towns are Digne (7751 inhabitants in 1896), Barcelonnette, Castellane, Forcalquier, Sisteron, and Manosque. In 1896 there were 604 primary schools, with 18,757 pupils. Nine per cent. of the population was illiterate. The soil of the department is poor in the mountainous region, but more fertile in the valley of the Durance, especially in the neighbourhood of Manosque. The surface under cultivation comprised 841,380 acres in

1896, of which 345,800 acres were in cereals, 172,900 acres in forest, and the rest in grass. The value of the wheat crop in 1899 was £432,810. Rye, barley, oats, as also fodder, give inferior returns, but olive and mulberry are cultivated with success, and the rearing of the silkworm yields good results—2283 cwts. of cocoons in 1899. There are few horses, but the Basses Alpes is among the departments most abounding in mules. In 1899 the live stock numbered 13,570 head of mules and asses, 5920 cattle, 318,350 sheep, 30,270 pigs, and 25,420 goats. The mining industry is not important, counting in 1899 about 3000 tons of coal and 5000 tons of lignite, and the industry in metals comprises only a few workshops. Altogether the department ranks among the least rich in France.

Alpes, Hautes, a department in the S.E. of France, traversed by the Alps of the Dauphiné, attaining in the Oisans Mountains 12,000 to 13,000 ft. high, and watered by the Drac and the Durance. Area, 2178 square miles, distributed among 24 cantons and 187 communes. The population declined from 122,924 in 1886 to 106,857 in 1901. Births (1899), 2519, of which 68 were illegitimate; deaths, 2413; marriages, 703. The chief towns are Gap, Briançon, and Embrun. In 1896 the primary schools numbered 600, with 24,708 pupils. Four per cent. of the population was illiterate. The soil is extremely poor. Out of 795,340 acres under cultivation in 1896, only 212,420 acres were utilized for cereals. In 1898 the wheat crop was of the value of £274,325, by the side of which may be ranked only that of the walnut, the plum, and the mulberry. The production in silk husbandry in 1899 amounted to only 363 cwts. of cocoons. There is no mining or metallurgic industry of any importance.

Alpes Maritimes, a department of the S.E. of France, bordering on Italy. It is traversed by the Alps and watered by the Roya and the Var. The climate is mild on the coast, but cold in the interior. Area, 1444 square miles, distributed among 26 cantons and 153 communes. Population, 238,057 in 1886, 265,155 in 1896, and 320,822 in 1901. There is a strong current of Italian immigration. Births in 1899, 6438, of which 658 were illegitimate; deaths, 6037; marriages, 1848. The chief towns are Nice (93,150 inhabitants in 1896), Grasse, Puget-Théniers, and Cannes. In 1896 there were 480 primary schools, with 24,000 pupils. Seven per cent. of the population was illiterate. The total surface under cultivation was 501,410 acres, of which 156,845 acres were in corn-lands, and 34,580 acres in vineyards. Cereals and fodder yield small returns—wheat (1899) only £212,720; but the production of wine was of the value of £135,000, while the department takes the first rank for the culture of the olive, which amounted in 1899 to 893,000 cwts. Orange and citron, which are also grown, yielded 113,500 cwts. The live stock in 1899 counted altogether 146,050 head, a very low figure, and not compensated by the industrial development. There are some important distilleries.

Alphabet. See WRITING.

Alphonso XII. (1857-1885), king of Spain, the son of Isabella II. and Maria Fernando Francisco de Asis, eldest son of the duke of Cadiz, was born 28th November 1857. When Queen Isabella and her husband were forced to leave Spain by the revolution of 1868 he accompanied them to Paris, and from thence he was sent to the Theresianum at Vienna to continue his studies. On 25th June 1870 he was recalled to Paris, where his mother abdicated in his favour, in the presence of a number of Spanish nobles who had followed the fortunes of the exiled queen. Shortly afterwards he proceeded to Sandhurst to continue

his military studies, and while there he issued, on 1st December 1874, in reply to a birthday greeting from his followers, a manifesto proclaiming himself the sole representative of the Spanish monarchy. At the end of the year, when Marshal Serrano left Madrid to take command of the northern army, General Martinez Campos, who had long been working more or less openly for the king, carried off some battalions of the central army to Sagunto, rallied to his own flag the troops sent against him, and entered Valencia in the king's name. Thereupon the president of the Council resigned, and the power was transferred to the king's plenipotentiary and adviser, Canovas del Castillo. In the course of a few days the king arrived at Madrid, passing through Barcelona and Valencia, and was received everywhere with acclamation. In the following year, 1876, a vigorous campaign against the Carlists, in which the young king took part, resulted in the defeat of Don Carlos and his abandonment of the struggle. Early in 1878 Alphonso married his cousin Princess Maria de las Mercedes, daughter of the duke de Montpensier, but she died within six months of her marriage. Towards the end of the same year a young workman of Tarragona, Oliva Marcousi, fired at the king in Madrid. On 29th November 1879 he married a princess of Austria, Maria Christina, daughter of the Archduke Charles Ferdinand. During the honeymoon a pastrycook named Otero fired at the young sovereigns as they were driving in Madrid. In 1881 the king refused to sanction the law by which the ministers were to remain in office for a fixed term of eighteen months, and upon the consequent resignation of Canovas del Castillo he summoned Sagasta, the Liberal leader, to form a Cabinet. Alphonso died of phthisis, 24th November 1885. Coming to the throne at such an early age, he had served no apprenticeship in the art of ruling, but he possessed great natural tact and a sound judgment ripened by the trials of exile. Benevolent and sympathetic in disposition, he won the affection of his people by fearlessly visiting the districts ravaged by cholera or devastated by earthquake in 1885. His capacity for dealing with men was considerable, and he never allowed himself to become the instrument of any particular party. In his short reign peace was established both at home and abroad, the finances were well regulated, and the various administrative services were placed on a basis that afterwards enabled Spain to pass through the disastrous war with the United States without even the threat of a revolution. (G. F. B.)

Alps.—The writer of the article "Alps" in the ninth edition of this work possessed a more intimate knowledge of that chain than any of his contemporaries. Hence, so far as regards ordinary geography, nothing of importance in it calls for alteration. New surveys have occasionally somewhat altered the heights assigned to mountains, a few of which are noticed below, together with one or two minor corrections or additions; but in one respect, the geology of the Alps and its relation to their structure, very great advances have been made during the last thirty years, and to a brief outline of these this supplementary article will be mainly devoted. Much, no doubt, has yet to be learnt; many questions are still far from being settled; but the labours of numerous investigators, German, Austrian, and Swiss, with some Italian and English, aided especially by the application of the microscope to the examination of rocks, have cleared up not a few difficulties, and laid a safe foundation for future work.

Perhaps the most important advance has been the knowledge gained in regard to the metamorphic rocks, viz., those in which subsequent changes have so affected the original structure that we infer rather than recognize

what it has been. Formerly most geologists supposed that all schists (using the word in its strict sense of foliated crystalline rocks), together with saccharoidal marbles and gneisses, resulted from the alteration of sediments by the combined action of heat, pressure, and water; some even going so far as to maintain that certain igneous rocks represented the extremest stage of this process. In their opinion a mud, if of the right chemical composition, might become in the first stage a schist, in the next a gneiss, in the last a granite. This kind of change, it was believed, had occurred during every geological period, so that, in the one or the other of these, schists and gneisses were identified without hesitation. Hence Mr Ball not infrequently mentions various Palæozoic schists. But, whatever may be the case elsewhere, we may venture to affirm that in the Alps all the rocks thus modified are much more ancient than any to which a date can be assigned. Though in most districts we can only prove them pre-Carboniferous, in the north-eastern region they are pre-Silurian, and in all it is highly probable that they are older than the Palæozoic era, as usually understood. Every effort to strengthen the old hypothesis, and not in the Alps only, has signally failed. For instance, in 1888 two large stems of a fossil plant were asserted to have been found in a gneiss at Guttannen in Canton Berne, thus proving it to be Carboniferous in age; in 1900 this supposed organism was admitted to be a mere *lusus naturæ*. In 1888, also, garnets and staurolites were said to occur in a rock in which belemnites and crinoids could still be recognized, thus establishing the Jurassic age of a great group of schists. In 1890 it was demonstrated that this far-reaching hypothesis had no better foundation than an erroneous identification of the two minerals, those actually present having no real bearing on the question.

Of the advances, mentioned above, none is more important than the recognition of the effects due to severe pressure. That it had produced cleavage in ordinary sediments was long since generally admitted; that in some cases it had generated minute scales of mica in vast numbers and converted a slate into a "microscopic" schist was

Effects of pressure on Alpine rocks.

more than conjectured; but it is now ascertained that crushing due to the great earth movements which have formed mountain chains has produced cleavages even in crystalline igneous rocks, and led to the development of various minerals, especially in connexion with the new surfaces, so that many gneisses and some mica schists are only granite modified by subsequent pressure. Other gneisses, however, and certain cognate schists, especially those with a conspicuous mineral banding, are the result of fluxional movements in the magma at the time of consolidation; while a third group of schists, and possibly some gneisses, may be explained by the old hypothesis. One difficulty doubtless still exists: in certain instances it is almost impossible to determine whether a very fine-grained schist represents a stage in the last-named process or results from the pulverization of a crystalline rock. This uncertainty, however, does not vitiate the general statement that a group of true schists can be distinguished from one composed of sediments in which changes only of microscopic magnitude have occurred, neither does it prove that the two may be present in the same geological formation; it only shows that in certain cases nature has so damaged her own inscription that it is no longer legible.

Thus, the following facts in regard to the nature and age of the Alpine rocks would now be generally admitted by those who have studied them in the field as well as under the microscope. Those rocks (mainly sedimentary) which can be assigned to a definite geological age rest

upon a fundamental crystalline mass of much greater antiquity. This appears to be separable into two groups, generally, though not always, rather sharply distinguished. The lower one consists mainly of granitoid rocks and gneisses, the majority, if not the whole, being igneous rocks modified by subsequent pressure. Some are later in date than others; for instance, the protogine of the Mont Blanc range, long supposed to be the oldest rock, is clearly intrusive in the adjacent gneisses. The upper group is mainly composed of mica schists, commonly calcareous, passing on the one hand into marbles, on the other to quartz schists; being thus metamorphosed sediments. With these are associated, sometimes abundantly, hornblende and chloritic schists, in great part at least modified igneous rocks. Rocks of similar character occur also, though less frequently, in the other group; and normal granites, gabbros, and serpentines in both, the age of which has not yet been certainly determined.

Age of the Alpine rocks.

These rocks, the foundation-stones of the Alps, are followed, but so far as is known only in the north-eastern region, by sedimentary deposits of Silurian and Devonian age. Representatives of the Carboniferous system are more widely distributed, though generally in isolated strips, folded in among the crystalline masses. These are commonly dark in colour, and vary from good slates to coarse conglomerates or breccias, which often are full of pieces of the older schists and gneisses. They occasionally contain plant remains or a little anthracite, but marine fossils occur in the Gailthal and elsewhere in the Eastern Alps. The Permian system also is generally represented sporadically, as a rule by grits and conglomerates, indicating that high ground existed in the neighbourhood; but during this period the region of the South-eastern Alps was the scene of volcanic activity, which produced the great masses of "porphyry" around Botzen and Predazzo, which can be traced westwards beyond the lower end of Lago Maggiore. Outbreaks of this age can be detected in other localities, as on the Windgelle and to the east of Vernayaz, on the right bank of the Rhone. In South-eastern Tyrol the volcanic discharges continued into the Triassic period, and were renewed, in the opinion of some geologists, at a much later date. In this district the Trias is represented by sedimentary strata, consisting largely of pure dolomitic limestones, some of which have been thought to be coral reefs. Be this as it may, the existing mountains can hardly represent ancient atolls, as some have supposed. At this period, also, the surface contours of the Alpine region must have been very irregular, for in other parts, notably in the Pennine, Central, and Dauphiné Alps, the Trias is either absent or is represented by friable limestones and even gypsum, often not more than a few feet in thickness.

In regard to the rest of the Mesozoic and the Kainozoic systems, little need be added to the account given in the ninth edition of this work, except in regard to a perplexing deposit called the Flysch. It is a thick mass of mudstones, more or less gritty and generally unfossiliferous, which, it is now ascertained, represents identity of physical conditions rather than exact contemporaneity of deposit. In the northern part of the Eastern Alps it begins before the close of the Cretaceous period; in the southern its greatest extent is from the top of the Middle Eocene to that of the Middle Oligocene. In the Western Alps it ranges, in the Swiss portion, from the bottom of the Middle Eocene to the top of the Lower Oligocene, while in the south it does not begin till the Upper Eocene. It contains locally beds of breccia and even large isolated boulders, the volume of which is sometimes, as in the Habkernthal, several cubic yards, representing granites

not known to occur elsewhere in the Alps; in other places, for example near Sepey, the erratics may not have come from any great distance. But it is difficult to account for their presence. Ice is the most obvious means of transport; but the temperature during Eocene and Oligocene ages appears to have been much higher than it now is, being at a maximum in the former, while no evidence can be found of the existence of mountains on or near the present site of the Alps. Some authorities place the requisite range immediately to the north, supposing its roots to be buried beneath the Miocene deposits of the Swiss lowlands, but it would be strange if such an important mass had so quickly vanished and left "not a rack behind."

A geological map of the whole Alps, on a scale large enough to indicate clearly the above-mentioned divisions, shows them to be arranged in zones which are rudely symmetrical with the outline of the chain, the crystalline rocks occupying its central portion. But on examination irregularities appear which are far from unimportant. The southern sedimentary zone, for instance, gradually becomes attenuated as it is followed from its eastern end westwards, till it disappears rather beyond Lago Maggiore, after which crystalline rocks rise directly from the Piedmontese plain. The structure of the chain, also, is the most simple in its eastern part, a central range of crystalline rock forming the watershed, with two masses of sedimentary rocks flanking it north and south, through which the rivers have cut their paths. But this structure, as we approach the headwaters of the Inn, becomes more complex, as we shall explain in speaking of the hydrography, the change being probably connected with a feature in the geology. The outcrops of the rocks, as we have said, conform to the general course of the chain at its eastern end, trending almost west, but then they gradually sweep round the north Italian plain till at last they are almost parallel to their original direction. This structure, however, is modified by another of minor, but sometimes considerable importance, which is most conspicuously exhibited in the district about Lago di Garda. Here a broad belt of Mesozoic sedimentary rock, bounded on the south by a line extending approximately from Brescia to Verona, runs across the chain in a N.N.E. direction; flanked on the west by crystallines, and on the east, though less continuously, by the same and by great masses of Permian "porphyry." This belt may be traced by outlying patches across the central range until near Innsbruck it apparently dies out against the northern sedimentary range. It is in this neighbourhood, and the coincidence is significant, that the Alps attain their greatest width from north to south. Here, in fact, the dominant wave-like folds, of which the Alpine chain is composed, are traversed obliquely by a syncline. To the west of this, passing approximately between Chur and Mals, we find traces of a second syncline with the same general trend, but possibly subdivided by a central rise, while the structure of the crystalline rocks between the two main synclines hints at the existence of a corresponding anticline. A similar structure is suggested in the Bernina group, and yet farther to the west (in maps on a larger scale); while from Mont Blanc for a considerable distance to the south the whole chain has a general trend, in the same direction, and that is repeated by the outlying crystalline masses, the outcrops of which, as far as Dauphiné, run conspicuously from N.N.E. to S.S.W. How this structure is connected with the making of the Alps will be presently considered. But since ridge and furrow, swelling and dimple, are closely related on the earth's surface, any complete discussion of the physical history of the Alpine chain must regard it

as inseparable from the Apennines on the one side and the mountains of Istria and Dalmatia on the other, and as related in some way or other to the basin of the Adriatic and the plain of Northern Italy. But putting aside this more general question and restricting ourselves to the Alps proper, we must bear in mind two facts in any attempt to explain their complications:—(1) This chain was not the product of a single set of movements, but of two at least, which were separated by a considerable interval: the one occurring when the Eocene was passing into the Oligocene, the other in like way between the Miocene and Pliocene. (2) That the sedimentary masses thus affected were deposited on an irregular floor of more ancient, chiefly crystalline, rocks; parts at least of the present site of the Alps having been mountainous districts in Carboniferous and again in Permo-Triassic times. These irregularities in the thickness and strength of materials would cause corresponding inequalities in their resistance to pressure, and thus introduce numerous complications. Still, though allowance must be made for them, the general process in the rise of the Alps can be inferred from the experiments of A. Favre, H. M. Cadell, and Bayly Willis, and be described as follows:—Lateral pressures have formed a group of great folds in the earth's crust; these sometimes have been gradually bent over until their axial planes became inclined to the horizon. The strain occasionally has continued till the masses have been ruptured along these planes, and the upper portion of the fold has then slid on above the lower, thus producing an "overthrust fault." During these processes the less pliant crystalline masses are crushed and sheared, thus giving rise to structures analogous to cleavage, and often suggestive of bedding. The remarkable folding in the Alpine rocks has long been known, but the recognition of these other structures is comparatively recent, and its absence seriously detracts from the value of not a few geological maps and memoirs. One instance may suffice as an example:—The North Swiss Alps between the valleys of the Reuss and the Rhine, especially near the Glarnisch, exhibit a singularly complicated structure, the strata apparently being bent over to form a double fold, with complete inversion on both sides. No doubt the arrangement of the strata suggests this structure; but the mechanics of the process are so difficult to understand that Rothpletz with several other authorities explains it as a combination of overfolding followed by great overthrust faulting, and this seems to the present writer far more probable.

Another perplexing structure may be mentioned here which is found in certain mountains on the northern face of the Alps, such as the Mythen and Stanzerhorn, and has of late attracted much attention. These, called Klippen, are abrupt pyramidal masses, the beds in the upper part being not only older than those in the lower, but also "contorted, fractured, crushed, and mixed up," while the newer are comparatively undisturbed. They are due to overfolding and overthrusting, being remnants of larger masses, the greater part of which has been removed by denudation; but that they have been forced into their present position from so great a distance as the Briançonnais, as some have suggested, is hardly possible.

It is now generally admitted that the valleys in mountain regions are mainly the results of denudation, though the movements and structures of the uprising land masses must have done much, especially at first, to determine the directions in which the water ran. Thus the Alpine valleys may be divided broadly into valleys of dip and valleys of strike—the former, as the name implies, following the dip of the strata, and so being the narrower and steeper; the latter running

*Hydro-
graphy.*

along their outcrop, and thus the broader and more level. These are generally excavated in a mass softer than those adjacent on either side, whether it is intercalated or infolded. When this mass is prolonged for a great distance the strike valleys are sometimes divided by low watersheds into different drainage systems. Of this, the Upper Rhone, the Reuss at its outset, and the Vorder Rhein afford an excellent example. They are excavated in an infold, composed mainly of Jurassic rocks, which is divided by watersheds at the Furka and Oberalp passes. As valleys of strike are both supplied and drained by valleys of dip, the course of an Alpine river, unless affected by some of the irregularities mentioned above, has a rude resemblance to the outline of a flight of steps.

In the Eastern Alps, and in the southern more than in the northern region, the main lines of drainage run towards the east. The precise cause is not easily determined, but probably it is connected with the rather abrupt cessation of the chain at this extremity. The watershed then follows the central or crystalline range until on approaching the upper part of the Inn valley it bends towards the south, returning from the Maloja Pass, in the neighbourhood of the Rheinwaldhorn, nearly to its former position. Thus the upper waters of the Inn and the Hinter Rhein are supplied from a district distinctly south of the usual line of the watershed. The precise cause of this flexure is also difficult to determine, but it is probably connected with the syncline, mentioned in a former paragraph. The watershed afterwards follows the crest of the Lepontine and Pennine Alps, having to the north a second range—largely consisting of crystalline rocks—the Bernese Oberland—higher than the former and not much inferior to the latter, through gashes in which the Reuss and the Rhone discharge their waters. From this we infer that the structure of this region, when the river system of the Alps was first determined, was a simpler one, more like that of the Eastern Alps; the Pennine Alps, forming a watershed, flanked on either side by sedimentary ranges, of which the southern has been removed by denudation, and the northern greatly exaggerated by a later series of movements, which, however, must have been slow enough to allow the rivers to deepen their valleys *pari passu* with the rise. Though the range of Mont Blanc is connected with that of the Oberland, its crest forms the watershed, for this passes from the Great St Bernard over the low gap of the Col Ferret, and by the Little St Bernard returns to its former course at the Rutor; a diversion probably due to the exceptional elevation of the northern range in the vicinity of Mont Blanc, which has enabled it to discharge part of its water into the Val d'Aosta. Its original inferiority is, however, suggested by the fact that one tributary of the Durance actually drains the north-eastern flank of the now-dominant *massif*. South of the Little St Bernard Pass the watershed keeps in its old position along the crest of the crystalline mass which encloses the Italian plain, while the prolongation of the Mont Blanc *massif* may be traced through the Tarentaise and Maurienne as far as the High Alps of Dauphiné. The structure of these masses, however, is anything but simple. The Romanche, rising on the Col de Lautaret, forces its way through two crystalline ranges, that of the Grandes Rousses and of the Belledonne, between which is an infold of Jurassic rocks. Do these two crystalline masses, together with the other and larger one, represent the double range system (Mont Blanc and the Brevent) farther north; or should the chief Dauphiné mass (that around the Pointe des Écrins) be connected, as some think, with the crystalline ridge, of which the Grande Casse and Mont Pourri form parts; or is this latter ridge merely an outlier of the great central system, which farther

north is represented by the Pennines? The fact that the zone of the Briançonnais (an important trough of sedimentary rocks) in the main keeps to the west of the Grande Casse-Pourri *massif* seems to link the latter to the central system.

It is generally admitted that, whatever be the case in regard to Mont Blanc, the headwaters of streams flowing towards Italy have frequently trespassed on those running in the opposite direction. The most striking instance is afforded by the Maloja Pass. Here the head of the Inn valley is an almost level trough, about 9 miles long, between lofty mountains, which is terminated at the actual pass by precipices descending to the Val Bregaglia. But it is inferred from studying the surrounding district that the watershed once lay some 6 miles farther south, the Val Forno and Val Albigna being then tributaries of the Inn, but that it has been completely cut away by the greater erosive action of the Maira, which has annexed the drainage of these two glens. Those shorter trenches, which afford a passage to the great Alpine roads, may be similarly explained, and such apparent anomalies as the structure of the mountains near Zermatt. Here the truncation of the range between the two arms of the Visp at the Strahlhorn, the wide gap between it and Monte Rosa, and the apparent disappearance of the Gornegrat-Stockhorn spur, may be due to the recession of the head of the Val Anzasca.

The Alpine chain, as it exists, is the result of two separate sets of movements during the Tertiary era in a region which, as stated above, had already been the scene of disturbances. But the history of the former set is not yet certain. Some authorities think that the apparent change in general structure, near the headwaters of the Inn, indicates that the Alps to the east and the west were produced by independent disturbances. But even if the other view be adopted, the movements may not have been uniform or quite simultaneous. The effects of the second set were, at any rate, more marked in the Central and Western Alps, as is shown by the facts already mentioned, and by the upheaval of the nagelfluë (gravel from the rivers of the Oligocene Alps), to full 6000 feet above sea-level in the Rigi and the Speer. Some recent writers have maintained that parts of the Alps have been affected by torsional movements. It is, however, difficult to understand the mechanical conditions under which such movements, in the strict sense of the term, could be produced in the earth's crust, though no doubt unequal resistances to pressure and the joint effects of successive sets of thrusts, acting in different directions, would present a very similar aspect. Apart, however, from this it has been demonstrated, especially since 1870, that the structure of the Alps is far more complicated than was formerly supposed. It was also believed that in the Alps igneous rocks of Tertiary age occurred only in the Vicentin and in one or two isolated spots; recently, however, it has been maintained (though the question is still *sub judice*) that some of the intrusions in the Dolomite district belong to this era instead of to the Trias.

Much attention has been given to the movements and physics of glaciers. In the Alps their average motion is not far from a foot a day; while the study of other regions has shown that, *cæteris paribus*, the larger the glacier the quicker its pace. Special attention has been paid to the changes in volume exhibited by the Alpine glaciers. These are sometimes irregular, but as a rule they affect the majority of glaciers almost simultaneously. A universal shrinkage set in soon after 1860, but now the tide seems to have turned. The diminution in some cases has been very great; for instance, the thickness of

Movement of the larger watersheds.

Relation of the movements.

Glaciers.

the Unter Grindelwald glacier has been reduced by 115 feet. Its periods of advance during the last two centuries were 1703-20, 1770-1779, 1814-1822, 1840-1855. It is now generally agreed that during the Glacial epoch the Alpine ice more than once advanced and retreated. For instance, the glacier of the Rhone not only welled up against the flank of the Jura, where it dropped the noted *Pierre-à-bot* and other erratics, but also descended to within a few leagues of Lyons, thus attaining a total length of about 270 miles. As an example of fluctuation we may take the ancient Limmatt glacier, which many authorities believe to have exhibited the following phases:—(1) First advance indicated by morainic deposit on the Uetliberg; (2) Retreat and formation of the Deckenschotter (coarse conglomerate); (3) Second advance (extension to Jura) represented by moraines considerably above the level of the Lake of Zurich; (4) Retreat and deposit of the gravels forming the valley plain of the Limmatt; (5) Third advance, limited by the moraine near Killwangen. That most of the Swiss lowland was for a time covered by ice (forming a huge "piedmont" glacier) is now generally admitted. This would require the mean temperature to be much lower than at present, probably about 18° F. at the time of maximum extension, while the glaciers would practically disappear from the Alps with a rise of 9° F.

The hypothesis attributing the greater lake basins in the Alps to the erosive action of glaciers has been declining in favour during the last thirty years, as the subject has been more thoroughly and precisely studied. Many, perhaps the majority of geologists now admit that the action of glaciers is *abrasive* rather than *erosive*, and that they can excavate only in special circumstances and to a limited extent. Some tarns or lakelets may have been thus formed; in others the water is dammed back by old moraines or berg-falls; in others (though not Lago di Tremorgio) a hollow has been formed by the removal of soluble rock; but the larger Alpine lakes are now more generally attributed (like those of the St Lawrence region) to differential movements in the beds of pre-existing valleys.

A few corrections and additions to the article in the ninth edition of this work may be noted here. In regard to the Alpine mammals it is now certain that the ibex or bouquetin is restricted to the Eastern Graians. The brown bear still occurs in one or two of the more remote districts, with the lynx and wild cat. The stoat (*P. erminea*) ranges up to 10,000 feet. The golden eagle, though rare, and the raven may be added to the birds; one or two of the small *raptores* are not uncommon; the black redstart, the siskin, the crested titmouse, the crossbill, and the nutcracker are not rare; the wall-creeper (*Tichodroma muraria*), the Alpine accentor, the Alpine pipit, and the snowfinch occur in the upper region. "Grouse" in the list of game birds presumably means the hazel grouse, for of course *Tetrao scoticus* does not occur; the ptarmigan is rather common well above the tree-line, and ranges to a great height. The blackhead and common gull frequent the lakes, with the black and common terns. In the mountain lakes *Salmo lacustris* has been found at 8626 feet, and *Triton alpestris* slightly above that elevation. On page 621, col. 1 (*Ency. Brit.* ninth edition, vol. i.), the Piz Tremoggia (11,322 feet) and Piz Cambrèna (11,834 feet) hardly deserve to be called dominant peaks of the Bernina group. The height of the Gross Venediger is 12,008 feet.

Even since 1875 the Alps have been made much more accessible. Railways have been carried over the Brenner, Arlberg, and Brünig passes, and through the Mont Cenis and the St Gothard by the aid of long tunnels. The piercing of the Simplon is now in progress. Several light railways on more than one plan have been constructed, as that from Chur to Thusis, or from Visp to Zermatt, those up the Rigi, Pilatus, over the Wengern Alp, even up the Gornergrat; the latest attempt being to burrow up to the summit of the Jungfrau. Carriage roads have replaced mule paths, as at the Lukmanier, Flüela, Oberalp, and Col de Forclaz passes, also to Chamouni from Vernayaz by Salvan, and in several other places. Club-huts have been erected in many convenient positions among the peaks and glaciers; hotels have multiplied, not only in the villages but also on commanding situations. One has even been

built on the Gornergrat, thus ruining the grandest readily accessible point of view in the Alps. The result has been to flood many parts of the Alps with tourists, to whom their beauties make no real appeal, and thus to take away much of their charm.

In several instances new surveys have slightly altered the altitudes of peaks or passes given in Mr Ball's list; but it has been thought sufficient to substitute exact figures for those which he was obliged to leave as approximations, except in two or three cases where the writer has failed to obtain more precise information.

For topographical information, see the publications of the English, French, Italian, Swiss, German, and Austrian Alpine clubs; the well-known guide books of Murray, Baedeker, and Joanne, the Climbers' Guides, the *Guide du Haut Dauphiné*; Ball's *Alpine Guide* (new edition, vol. i. "Western Alps," edited by W. A. B. Coolidge, 1898, alone published); and *Notes for Travellers in the Alps* (1899), by the same editor (being the "General Introduction" to Ball's *Guide*, revised and rewritten). This last contains a list of all the more important books and maps on the Alps, with articles on their geology and physical geography, natural history, social life, &c. Among the more important books published of late years may be mentioned the following:—BAILLIE-GROHMAN, W. A. *Sport in the Alps*, 1896.—CONWAY, SIR MARTIN. *The Alps from end to end*, 1895.—DENT, CLINTON T. *Mountaineering* (Badminton Library), 1892.—FORBES, J. D. *Travellers through the Alps* (revised and annotated by W. A. B. Coolidge, 1900).—FRESHFIELD, D. W. *The Italian Alps*, 1875.—GÜSSELD, PAUL. *In den Hochalpen*, 1886.—LENDENFELD, R. von. *Aus den Alpen*, 2 vols., 1896.—LUBBOCK, SIR JOHN. *The Scenery of Switzerland*, 1896.—MAIN (BURNABY), MRS. *The High Alps in Winter*, 1883.—MATHEWS, C. E. *The Annals of Mont Blanc*, 1898.—ROMAN, J. *Dictionnaire Topographique du Département des Hautes Alpes*, 1888.—SINIGAGLIA, L. *Climbing Reminiscences of the Dolomites* (trans.), 1896.—SOWERBY, J. *The Forest Cantons of Switzerland*, 1892.—UMLAUF, F. *Die Alpen*, 1887 (*The Alps*, 1889).—WHYMPER, E. *Chamonix and the Range of Mont Blanc*, 1897; *The Valley of Zermatt and the Matterhorn*, 1897.

The list of papers and books on Alpine geology and physical

geography is also very extensive. Of the former the more important have appeared in some of the following publications:—*Académie des Sciences de l'Institut de France* (Comptes Rendus); *Accademia Reale dei Lincei* (Atti); *Annales des Mines, Deutsche geologische Gesellschaft* (Zeitschrift); *Geological Society of London* (Quarterly Journal); *Kaiserliche Akademie der Wissenschaften* (Vienna) (Sitzungsberichte); *Königliche Bayerische Akademie der Wissenschaften* (Sitzungsberichte); *Società Geologica Italiana* (Bollettino); *Société Géologique de France* (Bulletin); *Neue Denkschriften der allgemeinen Schweizerischen Gesellschaft*. The last-named contains (vol. xxxvii.) an important paper by Dr ZSCHOKKE, on the "Fauna of the higher Mountain Lakes," and one by Dr BALTZER (vol. xxxiii.) on the "History of the Unter-Grindelwald Glacier."—The following more special books may be added:—BARETTI, M. *Geologia della Provincia di Torino: Atlas*, 1895.—DIENER, C. *Der Gebirgsbau der Westalpen*, 1891.—FRAAS, E. *Scenerie der Alpen*, 1892.—FRECH, F. *Die Karnischen Alpen*, 1892.—HEIM, A. *Untersuchungen über den Mechanismus der Gebirgsbildung* (2 vols. and atlas), 1878; *Handbuch der Gletscherkunde*, 1885.—MOJZISOVICS, E. von. *Die Dolomitriffe von Stüdtirol und Venetiens*, 1879.—SÜESS, E. *Die Entstehung der Alpen*, 1875. See also *Das Antlitz der Erde. Livret-Guide Géologique dans le Jura et les Alpes de la Suisse*, 1894.—FAVRE and SCHARDT. *Eclogæ Geologicae Helveticæ* now contains summaries of papers on Alpine geology.

The following works are official:—*Austria: K. K. Geologische Reichsanstalt* (Abhandlungen und Jahrbuch). *France: Bulletin des Services de la Carte Géologique de la France*. *Italy: Reale Comitato Geologico d'Italia* (Bollettino). *Switzerland: Beiträge zur geologischen Karte der Schweiz*.

The Alps, at least up to the frontier, are included in the Government maps of the following countries:—*Austria: "Special Karte des österreichisch-ungarischen Monarchie,"* scale $\frac{1}{75,000}$, 763 sheets, 1874-1888; a revised edition now appearing.—*France: "Carte de l'État Major"* (type 1889), scale $\frac{1}{50,000}$, 258 sheets.—*Italy: "Carta Topographica del Regno d'Italia,"* scale $\frac{1}{100,000}$, 277 sheets, 1884-97.—*Switzerland: "Topographischer Atlas der Schweiz"* (Siegfried atlas), scale $\frac{1}{50,000}$ for mountains, 589 sheets, 1870.—Others, with maps of special districts, are enumerated in *Hints and Notes for Travellers in the Alps*, cli., and a list of geological maps is given (p. xcvi.). The best and most recent geological map of the whole chain is F. NOË, *Geologische Uebersichtskarte der Alpen*, $\frac{1}{1,000,000}$, 1890. (T. G. B.)

Alsace-Lorraine, in German *Elsass-Lothringen*, a German Imperial territory formed out of the former French provinces of Alsace and Lorraine, lying between the Rhine on the E., the Bavarian Palatinate, Prussian Rhine province, and grand-duchy of Luxemburg on the N., France on the W., and Switzerland on the S. Maximum length, N. to S., 118 miles; maximum breadth (in the N.), 106 miles; maximum breadth (in the S.), 22 miles. The determining features of its physical conformation are the Vosges Mountains and the Rhine. The foothills of the former and the valley of the latter account for almost the entire area of Alsace; and the greater part of Lorraine belongs to the high-plain which stretches from the Moselle to the Saar, but seldom rises to 1300 feet above the sea-level. The drainage of the Vosges valleys and of the Rhine valley is collected and carried into the Rhine about 10 miles below Strasburg by the Ill. The climate is on the whole temperate—warmest in the lowest districts (460 ft. above sea-level) of N. Alsace, and coldest on the summits of the Vosges, where snow lies six months in the year. The mean annual temperature at Strasburg is 49.8° Fahr., at Metz 48.2°; the rainfall at Strasburg 26½ inches, and at Metz 27½ inches. The Rhine valley is in great part fertile, yielding good crops of potatoes, cereals (including maize), sugar beet, hops, tobacco, flax, hemp, and products of oleaginous plants. But wine and fruit are amongst the most valuable of the crops. The cereals chiefly grown are wheat, oats, barley, and rye. Great quantities of hay are harvested. In 1898 about 3000 acres were planted with tobacco, and the yield, when dried, weighed about 3000 tons; and 73,730 acres were planted with vines, the yield being 11,348,000 gallons of wine, valued at £950,000. These statistics embrace also the production of Lorraine, where agriculture is less strenuously carried on, and the fertility of the soil is less.

But Lorraine possesses, in compensation, greater riches in the earth, in her coal and iron and salt mines, the output of which in 1897 was 1,057,550 tons of coal, valued at £441,970; 5,360,840 tons of iron ore, valued at £615,880; and 70,578 tons of salt, valued at £39,860. The total mineral output of Alsace-Lorraine in 1898 was valued at £1,276,340. In 1897 the live stock of the territory numbered 138,689 horses, 512,329 head of cattle, 375,635 pigs, and 93,204 sheep. Cows are grazed on the S. Vosges in summer, and large quantities of cheese (Münster cheese) are made and exported. Total population (1901), 1,717,451.

The farms in Alsace are mostly small, and are held partly as a private possession, partly on the communal system; in Lorraine there are some larger occupations. The distribution and classification of the holdings was as follows in 1895:—

Under 2½ acres.	2½ to 25 acres.	25 to 250 acres.	Above 250 acres.	Total farms.
98,666	119,955	12,919	407	231,947

The total area of these 232,000 farms was 2,230,368 acres, the rest of the territory being covered by forests, barren lands, lakes, roads, &c. Agriculture and wine-growing are general industries; but coal and iron mining are special to Lorraine, as the manufacture of cottons, and on a smaller scale of woollens, is special to Alsace, the chief centres of the industry being Mülhausen, Colmar, and the valleys of the Vosges. The territory has always been the centre of an active commerce, owing to its situation on the confines of Germany, France, and Switzerland, and alongside the great highway of the Rhine. The communications embrace some 1090 miles of railway (1898: of which about 1000 miles belonged to the state), a good system of roads, and several canals, in addition to the rivers. Administratively the territory is divided into the following three districts:—

Districts.	Area in sq. miles.	Population.			Density per sq. mile, 1895.
		1875.	1885.	1895.	
Upper Alsace . . .	1854	453,874	462,549	477,477	352.6
Lower Alsace] . .	1945	593,190	612,077	635,624	346.1
Lorraine	2402	480,250	489,729	524,885	218.5
Total	5601	1,531,304	1,564,355	1,640,986	292.9

On the sex division, 833,173 were in 1895 males, and 807,813 females. The percentage of illegitimacy in the same year was 8.3, also in 1898. The rural population embraced 54.8 per cent. of the whole, the urban population 45.2 per cent. The largest towns are Strasburg (the capital of the territory), Mülhausen, Metz, Colmar, Hagenu, Saargemünd, Gebweiler, and Markirch, all above 10,000 inhabitants each. Classified according to religion there were, in 1895, 356,458 Protestants, 1,246,791 Roman Catholics, and 32,859 Jews. Education is provided for (1898) at the university of Strasburg, in 23 classical and pro-classical schools, in 13 modern schools, and in nearly 3500 schools of a more elementary character. Over 80 per cent. of the people speak German as their mother-tongue, the rest French, or a patois of French. The supreme executive officer of the territory is a governor-general, who is appointed by the German emperor; but he is assisted by a ministry of four members, under the chairmanship of a secretary of state, and by a council of state numbering 58 members, and consisting of the governor-general, secretary of state, chief provincial officials, and 8 to 12 nominees of the emperor. In 1900 the revenue was estimated at £3,020,242, and the expenditure at £3,002,733. There was also an extraordinary budget of £199,822 revenue and £217,362 expenditure. Customs and indirect taxes yield more than three-fifths of the total revenue, and direct taxes less than one-fourth. The state forests give about one-ninth of the whole. The public debt, capitalized, amounted in 1900 to £1,192,150, and the territory's contribution to the imperial exchequer to £880,425 in 1900. The higher administration of justice is devolved upon six provincial courts and a supreme court, sitting at Colmar. Moreover, there are purely industrial tribunals at Mülhausen, Thann, Markirch, Strasburg, and Metz. The fish-breeding establishment at Hüningen in Upper Alsace should be mentioned.

(J. T. BE.)

Alston, or **ALDSTONE**, a market-town and railway station in the Penrith parliamentary division of Cumberland, England, 29 miles by road E.S.E. of Carlisle. The preparation of umber for colours and paint is carried on. There are limestone quarries, and argentiferous lead, copper, and blende are found in the neighbourhood. Coal

is worked chiefly for lime-burning. Area of parish (under a rural district council), 36,968 acres; population (1881), 4621; (1891), 3384; (1901), 3133.

Altai, the name given to an extensive region of Southern West Siberia, composed of many mountain ranges and broad, fertile valleys, similar in character to, but covering an area nearly three times larger than, Switzerland (52,500 square miles). It is watered by the upper tributaries of the Ob—Biya, Katuñ, Charysh, and partly Tom, as also the Upper Irtysh. It has a quadrangular shape, and is bounded on the S.W. by the Black (Chorny) Irtysh, on the S.E. by the high plateau of North-western Mongolia, on the N.E. by the government of Yeniseisk, parts of which belong to or merge into the Altai, and on the N.W. by the lowlands of Tomsk, strewn with many lakes and watered by the Ob. The name of Altai—Ektagh Altai, or Southern Altai, or Chinese Altai, and Altain-nauru—is also given to a mountain range which separates the drainage area of Lake Kobdo from that of the Black Irtysh and its former tributary, the Ulungur. This range borders on the N.—as the Eastern Tian-Shan borders on the S.—the great and broad Dzungarian trench, excavated in a north-west to south-east direction in the High Plateau of East Asia, and leads with a gentle gradient from the lowlands of Lake Balkhash to the high level of the plateau.

The highest parts of the Altai region are along the border of the Mongolian plateau, where in all probability we have a border-ridge similar to the Western Sayan, which might be named the Sailughem range. Its south-eastern slope is short and gentle for the most part, as it leads to the 4000-5000 feet high plateau, upon which rise the tributaries of the Kemchik (Yenisei) at a great altitude, and the lakes Ubsa-nor and Kobdo are situated. Several small plateaus, such as the Ukök (7800 feet), Chuya (6000 feet), Kendykty (8200 feet), and Juvlukul (7900 feet) plateaus, situated along a common axis running south-west to north-east, enter into the composition of that mountain range. There is no tree vegetation on these heights; only the dwarf birch (*B. nana*) stands the cold, and the *Arctomys bobac* makes his furrows in the frozen mud. Easy passages lead from these alpine lands to the high plateau of Mongolia, but the slopes directed towards the Altai rivers are extremely steep and very difficult of access. The snow-line lies here at an altitude of about 9000 feet, and many summits rise above that level, especially the Byelukha (the Mont Blanc of the Altai), whose two summits reach 14,800 and 14,500 feet respectively, and give origin to six large and several small glaciers (30 square miles aggregate area). The Kuitun, 12,000 feet, and several other high peaks belong to the same range. Several chains of mountains fill up the space between the Sailughem and the lowlands of Tomsk, but their mutual relations are yet far from being well known, and they are mostly described under local names. Such are the Chuya Alps (Chuiskiye Byelki), having an average altitude of 9000 feet, with summits rising from 11,400 to 12,000 feet, and giving origin to at least ten glaciers on their northern slope; the Katuñ Alps (Katunskiy Stolby); the Kholzun range; the range which is known locally under the names of Korgon (Korgonskiye Byelki, 6300 to 7600 feet), Talitsk, and Selitsk ranges; the Tigeretsk Alps, and so on. Several secondary plateaus of lower altitude are also distinguished by geographers.

The picturesque and fertile valleys of the Altai, surrounded as they are by majestic alps, are, of course, better known. The Katuñ valley begins as a wild gorge on the south-west slope of the Byelukha peak; then the

river makes a great winding before it pierces through the Katuñ Alps, when it enters a wider valley, lying at an altitude of from 2000 to 3500 feet, which it follows until it emerges from the Altai highlands to join the Biya and to form the Ob by their confluence in a most picturesque region. The next valley is that of the Charysh, which has the Korgon and Tigeretsk Alps on one side and the Talitsk and Bashalatsk Alps on the other side. It is again very fertile, and is well peopled with Russian peasant immigrants in its lower parts. The Altai, seen from this valley, presents the most romantic scenes, including the small but deep Kolyvañ lake (altitude, 1180 feet), described by so many geographers, surrounded by fantastically-shaped granitic domes and towers. Farther west the valleys of the Uba, the Ulba, and the Bukhtarma open south-westwards towards the Irtysh. The lower part of the first is thickly populated; in the often-described valley of the Ulba is the Riddersk mine, at the foot of the 6770 feet high Ivanovsk peak, covered with beautiful alpine meadows. As to the valley of the Bukhtarma, which has a length of 200 miles, it also has its origin at the foot of the Byelukha and the Kuitun peaks, and as it falls from the 6195 feet high level of an alpine plateau to the Bukhtarma fortress (1130 feet) it offers the most striking contrasts of landscapes and vegetation. Its upper parts are rich in glaciers, the best known of which is the Berel, which flows from the double peak of the Byelukha. On the northern side of the mountain range which separates the upper Bukhtarma from the upper Katuñ one finds the Katuñ glacier, which, after two ice-falls, becomes from 700 to 900 yards wide, and is often described as the Altai *Mer de Glace*, while the Byelukha is described as the Altai Mont Blanc. From a grotto in this glacier wildly runs the Katuñ. The middle and lower parts of the Bukhtarma valley have been colonized since the 18th century by Russian peasant runaways—serfs and non-conformists—who had created there a free republic on Chinese territory; and after 1869, when this part of the valley was annexed to Russia, it was rapidly colonized, on account of the fertility of the wide prairies in its lower portion.

NORTH-EAST ALTAI.—The north-eastern Altai is much less known. High passes, of difficult access and over 10,000 feet of altitude, lead from it across the Sailughem to the Mongolian plateau; but they are seldom visited unless by Kirghiz shepherds. The high valleys of this portion of the Altai—Bashkaus, Chulyshman, and Chulcha, all three leading to the beautiful alpine lake Teletskoye (length, 117 miles; maximum width, 4 miles; altitude, 1600 feet) are only inhabited by nomad Telen-guts. Even the shores of the lake—reminding one of the Lake of the Four Cantons—are too wild to receive a numerous population. From this lake issues the Biya, which becomes navigable only after it emerges from the mountains, *i.e.*, at Biysk. Sixty miles below this town it joins the Katuñ, and here begin the beautiful prairies in the north-west of the Altai.

KUZNETSK DISTRICT.—Farther to the north-east the Altai highlands are continued in the Kuznetsk district, which has a slightly different geological aspect, but still belongs to the Altai system. At the south-east limits of this district the Sayan range (from 6000 to 8000 feet, or more) appears as a continuation of the Sailughem, and has the same border-ridge character. But the Abakan river, which rises on its north-western slope, belongs to the system of the Yenisei. The Kuznetsk Alatau range, on the left bank of the Abakan, runs north-east into the province of Yeniseisk, while a complex of imperfectly mapped mountains (Chukchut, Salaisk, Abakan, &c.) fills up the western portions of this territory. The Tom and its

numerous tributaries rise on the northern slopes of the Alatau, and their fertile valleys are occupied by a thick Russian population, the centre of which is Kuznetsk, on the Tom.

Geology.—The geology of the Altai is yet imperfectly known. Granite, together with porphyry and porphyrite, intersected by veins of jade (veined porphyrite) and various breccias used for decorative purposes at the Kolyvañ stone-cutting works, as also diorites, diabases, augite porphyry, hyperstenite, &c., enter to a large extent into the composition of its mountains. The granites are very much decomposed, and take fantastic shapes round Lake Kolyvañ. Volcanic basalts and andesites are found in the Salair range. The great bulk of the mountains consists of various schists, limestones, sandstones, &c., belonging to the pre-Silurian period, the Silurian, Devonian, and Carboniferous ages; they are chiefly developed in the northern outer parts of the Altai. Since the Carboniferous period the Altai has not been under the sea, and its coal-bearing Jurassic deposits are of fresh-water origin; only in the Alatau are they of marine origin, and show that this part of the highland was partially invaded by the sea during the Secondary age.

Numerous traces of an extended glaciation (including striated rocks) have been discovered by Prof. Sapozhnikoff. As a rule, the mountains are covered with thick diluvial deposits, and the forms of their granitic domes also suggest a wide glaciation.

Flora.—The flora of the Altai, explored chiefly by Ledebour, is rich and very beautiful. Up to a level of 1000 feet on the northern, and 2000 feet on the southern slopes, the flora is the habitual European flora which spreads in Siberia as far as the Yenisei. The steppe flora also penetrates from the south-west and drives the Altai flora to a still higher level. But above these levels up to 6000 feet, which is the average limit of tree vegetation, the mountains are covered with beautiful forests of birch, *Pinus cembra*, *Abies sibirica*, *Larix sibirica*, *Picea obovata*, and so on, while the meadows are clothed with a rich, brightly coloured, and typical covering of herbaceous plants. Even the alpine meadows, which have many species in common with the Alps, have a number of their own Altayan species.

Mineral wealth.—In respect of mineral wealth, the Altai proper is rich in silver, copper, lead, and zinc ores, while in the Alatau, gold, iron, and coal are the chief resources. The Alatau mines are only now beginning to be explored, while the copper, and perhaps also the silver ores of the Altai proper were already worked by the prehistoric "Chud," at a time when the use of iron was not yet known. Russians began to mine in 1727 at Kolyvañ, and in 1739 at Barnaul. But the Altai mines were made the property of the imperial family ("The Cabinet of His Majesty"), and the miners were made serfs, which they remained until 1861; and this circumstance hampered to a great extent both the development of mining and the colonization of the country. The ores of the Altai proper appear nearly always in the shape of irregular veins containing silver, lead, copper, and gold,—sometimes all together,—and they are worked chiefly at Zmeinogorsk (or Zmeieff); Zyryanovsk, Ust-Kamenogorsk, Riddersk (abandoned in 1861), and elsewhere. They offer, however, great difficulties, especially on account of their continually varying productivity and temperature of fusion. The beautiful varieties of porphyries—green, red, striped, &c.—which are obtained, often in big monoliths, near Kolyvañ, are cut at the imperial stone-cutting factory, whose produce is well known in the art galleries and palaces of Europe. Aquamarines of mediocre quality but enormous size (up to 3 inches in diameter) are found in the Korgon mine. The northern, or Salairsk, mining region also is rich in silver ores, and the mine of this name used formerly to yield up to 7776 lb of silver in one year. But the chief wealth of the north-east Altai is in the Kuznetsk coal-basin, also containing iron ores, which fills up a valley between the Alatau and the Salairsk range for a length of about 270 miles, with a width of about 65 miles, and is considered by Prof. Mushketoff as equal to the best coal basins of England and South Russia. Schmahlhäuser's researches prove that these Coal Measures belong, like all those of East Siberia, Turkestan, &c., to the Jurassic formation. The country is also covered with thick diluvial and alluvial deposits containing gold. Gold is extracted in many places in the Altai; to the extent of 2887 kilograms in 1897. However, all the mining is now on the decline. Instead of the 36,000 lb of silver which used to be extracted, only 6060 lb were extracted in 1897. The yield of lead was 33,000 cwts. in 1868-71, and 20,000 cwts. in 1895; of copper, 4400 cwts. in 1897. Coal, however, is being extracted in small quantities.

Population.—The Russian agricultural population has rapidly increased since the fertile valleys belonging to the imperial family have been thrown open to immigration, and it is estimated that the present agricultural population of the region (Biysk, Barnaul, and Kuznetsk districts) already reaches about 800,000. The natives may represent a population of about 45,000. They are Altayans in the west and Telenghites in the east, with a few

Kalmyks and Tatars. Although all called Kalmyks by the Russians, they speak a Turkish language. Both the Telenghites and the Altayans are Shamanists, but many of the former are already quite Russified. As to the virgin forests of the Kuznetsk Alatau—the Cherñ, or the Black Forest of the Russians,—they are peopled by Tatars (Chernevyis or Black Forest Tatars), who live in very small settlements, sometimes of the Russian type, but mostly in wooden *yurtas* of the Mongolian fashion. They can hardly keep any cattle, and live the poor life of forest-dwellers, feeding upon various wild roots, when there is no grain in the spring to be crushed with a hand-mill. Honey and cedar-nuts (from *Pinus cembra*) collected in the forests are much relied upon for buying grain from the Russians. Hunting and fishing are also resorted to, and the skins and furs are tanned by the family.

Agriculture.—The chief occupation of the Russians is agriculture (about 3,500,000 acres under culture), cattle breeding, bee culture (over 400,000 hives), mining, gathering of cedar-nuts (from 3000 to 10,000 cwts. yearly), and hunting. All this produce is exported partly to Tomsk and partly to Kobdo in Mongolia.

Towns.—The real capital of the Altai is Barnaul, the centre of the mining administration and altogether an animated commercial town (29,408 inh.); Biysk, which is the commercial centre (17,206 inh.); Kuznetsk (3140 inh.), Ust-Kamenogorsk (8958), and the mining towns Kolyvañ (11,703), Zmeinogorsk (6083), Riddersk (4000), and Salairsk (2500). Many villages are very populous.

Administration.—Most of the Altai region, covering an area of nearly 170,000 square miles and including the Kuznetsk region, forms a domain of the imperial family under the name of *Altai Mining District*.

Authorities.—RITTER'S *Asien*, LEDEBOUR'S *Reise*, TCHIKHATCHEFF'S *Altai*, and COTTA'S *Altai* are still very well worth consulting. Of modern works, *Zhivopisnaya Rossiya* ("Picturesque Russia"), vol. xi., by POTANIN, MUSHKETOFF, ADRIANOFF, and others; SEMENOFF'S *Geographical Dictionary*; ADRIANOFF'S "Journey to the Altai," in *Zapiski Russ. Geogr. Soc.* xi.; YADRINTSEFF'S "Journey in West Siberia" in *Zapiski West Sib. Geogr. Soc.* ii.; GOLUBEFF'S *Altai*, 1890 (Russian); SCHMURLO, "Passes in S. Altai" (*Sailughem*), *Izvestia Russ. Geogr. Soc.* 1898, xxxiv. 5; Prof. SAPOZHNIKOFF, various articles on glaciers, &c., in same periodical, 1897, xxxiii.; 1899, xxxv. (P. A. K.)

Altdorf, the capital of the Swiss canton of Uri, with a station on the St Gothard Railway, 22 miles from Göschenen and 34 miles from Lucerne. In 1899 a fine new carriage road was opened from Altdorf through the Schächenthal and over the Klausen Pass (6404 feet) to Linththal (30 miles from Altdorf), and so to Glarus. In 1895 a fine bronze statue of Tell and his son, by Kissling, was set up in the market-place. In 1899 a theatre, close to the town, was opened for the sole purpose of representing Schiller's *William Tell*. There is a stately parish church. Population in 1888, 2542; 1899, 2553; in 1900, 3134.

Altena, a town of Prussia, province Westphalia, 38 miles by rail S.S.E. from Dortmund. It has hardware (especially fine wire) industries, a castle, and a museum. Population (1885), 9387; (1895), 12,108; (1900), 12,769.

Altenburg, a town of Germany, capital of the duchy of Saxe-Altenburg, 23 miles S. from Leipsic by rail, with fine suburbs. A museum, with natural history, archaeological, and art collections, has been erected, and there may be mentioned St Bartholomew's church (1089), the German Renaissance town hall (1562-64), a lunatic asylum, teachers' seminary, and agricultural school. There are lignite mines in the vicinity. Population (1885), 29,110; (1895), 33,420; (1901), 37,110.

Altendorf, a commune of Prussia, in the Rhine province, 1 mile W. from Essen, with coal-mines and iron-works. It embraces the two colonies of Krupp's work-people—Kronenberg (population, 7764 in 1890) and Schederhof (4431). In 1901 it was incorporated with Essen. Population (1885), 25,693; (1895), 40,280; (1900), 63,271.

Altenessen, a commune of Prussia, in the Rhine province, 3 miles N. from Essen, with coal-mines, machinery factories, and lime-kilns. Population (1885), 15,599; (1895), 20,976; (1901), 27,938.

Alton, a city of Madison county, Illinois, U.S.A., situated in the western part of the state, on the eastern bank of Mississippi river, just above the mouth of Missouri river, and twenty-one miles above St Louis, at an altitude of 436 feet. It is built on the river bluffs, and its plan is fairly regular. It is entered by four railways. The population in 1880 was 8975, in 1890 it was 10,294, and in 1900 it was 14,210.

Altona, a town of Prussia, province Schleswig-Holstein, immediately W. of Hamburg, with which it is commercially identified, though administratively it is a separate town. Municipal offices, a bronze equestrian statue of the Emperor William I., and a bronze statue of Bismarck have been erected; there may also be noticed the public museum (containing ethnographical and natural history collections), and monuments of the wars of 1864 and 1870-71. Altona is the headquarters of the 9th German army corps, and possesses a school of navigation and famous fish-markets. Among its industries are the production of cottons, woollens, chemicals, chicory, hats, and varnish. Since 1888, when Altona joined the Imperial Zollverein, approximately half a million sterling has been spent upon harbour improvement works. The imports and exports resemble those of Hamburg (*q.v.*). In the ten years 1871-80 the port was entered on an average by 737 vessels of 67,735 tons, in 1881-90 by 608 vessels of 154,713 tons, and in 1891-98 by 839 vessels of 253,384 tons. In 1889 Ottensen (to the W. of Altona), where the poet Klopstock lies buried, was incorporated with the town. In 1885 (including Ottensen, Oevelgönne, Othmarschen, and Bahrenfeld) the population was 126,306; in 1895, 148,944; in 1900, 161,508; without the four suburbs, 113,526 (1895); 117,824 (1900).

Altoona, a city of Blair county, Pennsylvania, U.S.A., situated in 40° 32' N. lat. and 78° 24' W. long., at the foot of the Allegheny plateau, not far from the centre of the state, at an altitude of 1179 feet. It is on the main line of the Pennsylvania railway. The city is divided into nine wards, is regularly laid out, and is well built, having been in great part constructed by the railway corporation as its chief manufacturing depot. Fostered by the railway, it has had a very rapid and solid growth. The population in 1880 was 19,710, in 1890 it was 30,337, and in 1900 it was 38,973.

Altrincham, or ALTRINGHAM, a market town and railway station in the Altrincham parliamentary division of Cheshire, England, 8 miles S.W. by S. of Manchester. The more recent structures are a Baptist chapel, a Unitarian chapel, and a market hall. Area of township (an urban district), 662 acres. Population (1881), 11,250; (1891), 12,440; (1901), 16,831; of parliamentary division (1901), 78,796.

Altwasser, an industrial village of Prussia, province Silesia, 43 miles by rail S.W. from Breslau, and 3 N. from Waldenburg. It has factories for glass, porcelain, machinery, cotton-spinning, iron-foundries, and coal-mines. Population (1885), 8672; (1895) 10,207.

Altyn-tagh, or ASTYN-TAGH, a lofty mountain range of Central Asia, running from the S.W. to the N.E., from 38° N.-87½° E. to 39° N.-91° E., forms a border range of Northern Tibet, having to the north-west the lower terrace of the East Turkestan plateau, about 2700 feet high on the banks of the Cherchen-daria, and to the south-east the north-western extremity of the Tsaidam plateau, nearly 10,000 feet of altitude. In 89° 30' E. it is separated from the Tarim basin by a secondary chain, about 7200 feet high, but farther west it rises above the desert as a nearly vertical wall. The passes visited by Prjewalsky and Carey reach

10,140 and 13,000 feet respectively, the summit attaining from 12,000 to 14,000 feet. (See KUEN-LUN.)

Alt-Zabrze, a village of Prussia, province of Silesia, 5 miles by rail E. from Gleiwitz. It is in repute for its iron-works, coal-mines, manufactory of wire ropes, &c. Population (1885), 9390; (1895), 14,012; (1900), 19,571.

Aluminium.—Although never met with in the elemental state, the metal aluminium is more widely distributed throughout the world than any similar substance. The word is derived from the Latin *alumen*, and is probably akin to the Greek *άλς* (the root of *salt*, *halogen*, etc.); but while Pliny the Elder and other Roman authors discuss its properties at some length, there is considerable doubt whether the alum they knew was not largely composed of sulphate of iron. In the 16th century A.D., Paracelsus drew the first real distinction between alum and the vitriols; in 1722 Hoffmann announced the base of alum to be an individual substance; in 1761 Morveau suggested that this base should be called *alumine*, after *Sel aluminéux*, the French name for alum; and finally about 1820 the word was changed into *alumina*. In 1760 the French chemist Baron unsuccessfully attempted "to reduce the base of alum" to a metal, and shortly afterwards various other investigators essayed the problem in vain. In 1808 Sir Humphry Davy, fresh from the electrolytic isolation of potassium and sodium, strove to break up the molecule of alumina by heating it with potash in a platinum crucible and submitting the mixture to a current of electricity; in 1809, with a more powerful battery, he raised iron wire to a red heat in contact with alumina, and obtained distinct evidence of the production of an iron-aluminium alloy. Naming the new metal in anticipation of its actual birth, he called it *aluminium*; but for the sake of analogy he was soon persuaded to change the word to *aluminum*, in which form, alternately with *aluminium*, it occurs in chemical literature for some thirty years. The metal is occasionally called *aluminum* in America to this day; but the European spelling is preferable, as the termination *-ium* harmonizes with the names of other metallic elements.

In the year 1824, endeavouring to prepare it by chemical means, Oersted heated its chloride with potassium amalgam, and failed in his object simply by reason of the mercury, so that when Wöhler repeated the experiment at Göttingen in 1827, employing potassium alone as the reducing agent, he obtained it in the metallic state for the first time in history. Contaminated as it was with potassium and with platinum from the crucible, the metal formed a grey powder and was far from pure; but in 1845 he improved the conditions of his process, and succeeded in producing metallic globules wherewith he examined its chief properties, and prepared several compounds hitherto unknown. Early in 1854, H. St Claire Deville, who was attempting to make some non-existent salts of aluminium, accidentally and in ignorance of Wöhler's later results, imitated the 1845 experiment. At once observing the reduction of the chloride, he realized the importance of his discovery, and immediately began to study methods for winning the metal on a commercial scale. His attention was at first divided between two processes—the chemical method of reducing the chloride with potassium, and an electrolytic method of decomposing it with a carbon anode and a platinum cathode, which was simultaneously imagined by himself and Bunsen. Both schemes appeared well-nigh impossible: potassium cost about £17 per lb, gave a very small yield, and was dangerous to manipulate, while, on the other hand, the only source of electric current then available was the primary battery, and zinc as a store of industrial energy was utterly out of the question. Deville accordingly returned to pure chemistry and invented a practicable method of preparing sodium which, having a lower atomic weight than potassium, reduced a larger proportion. He next devised a plan for manufacturing pure alumina from the natural ores, and finally elaborated a process and plant which held the field for almost thirty years. So admirably and exhaustively were his researches conducted that it required a Castner to improve on his methods. Only the discovery of dynamo-electric machines and their application to metallurgical processes rendered it possible for the brothers Cowles to remove the industry from the hands of chemists, till the time when Messrs. Héroult and Hall, by devising the electrolytic

Preparation.

method now in use, placed the business finally under the control of electricians, and inaugurated the present era of industrial electrolysis.

The chief natural compounds of aluminium are four in number: oxide, hydroxide (hydrated oxide), silicate, and fluoride. *Corundum*, the only important native oxide (Al_2O_3), occurs in large deposits in southern India and the United States.

Ores.

Although it contains a higher percentage of metal (52.9 per cent.) than any other natural compound, it is not at present employed as an ore, not only because it is so hard as to be crushed with difficulty, but also because its very hardness makes it valuable as an abrasive. *Cryolite* ($Al_2F_6 \cdot 6NaF$) is a double fluoride of aluminium and sodium, which is scarcely known except on the west coast of Greenland. Formerly it was used for the preparation of the metal, but the inaccessibility of its source, and the fact that it is not sufficiently pure to be employed without some preliminary treatment, caused it to be abandoned in favour of other salts. When required in the Héroult-Hall process as a solvent, it is sometimes made artificially. Aluminium silicate is the chemical body of which all clays are nominally composed. *Kaolin* or *China clay* is essentially a pure disilicate ($Al_2O_3 \cdot 2SiO_2 \cdot 2H_2O$), occurring in large beds almost throughout the world, and containing in its anhydrous state 24.4 per cent. of the metal, which, however, in common clays is more or less replaced by calcium, magnesium, and the alkalis, the proportion of silica sometimes reaching 70 per cent. Kaolin thus seems to be the best ore, and it would undoubtedly be used were it not for the fatal objection that no satisfactory process has yet been discovered for preparing pure alumina from any mineral that is chemically a silicate. If, according to the present method of winning the metal, a bath containing silica as well as alumina is submitted to electrolysis, both oxides are dissociated, and as silicon is a very undesirable impurity, an alumina contaminated with silica is not suited for reduction. *Bauxite* is a hydrated oxide of aluminium of the ideal composition, $Al_2O_3 \cdot 2H_2O$. It is a somewhat widely distributed mineral, being met with in Styria, Austria, Hesse, and French Guiana; but the most important beds are in the south of France, the north of Ireland, and in Alabama, Georgia, and Arkansas in North America. The chief Irish deposits are in the neighbourhood of Glenravel, Co. Antrim, and have the advantage of being near the coast, so that the alumina can be transported by water-carriage. After being dried at $100^\circ C.$, Antrim bauxite contains from 33 to 60 per cent. of alumina, from 2 to 30 per cent. of ferric oxide, and from 7 to 24 per cent. of silica, the balance being titanic acid and water of combination. The American bauxites contain from 38 to 67 per cent. of alumina, from 1 to 23 per cent. of ferric oxide, and from 1 to 32 per cent. of silica. The French bauxites are of fairly constant composition, containing usually from 58 to 70 per cent. of alumina, 3 to 15 per cent. of foreign matter, and 27 per cent. made up of silica, iron oxide, and water in proportions that vary with the colour and the situation of the beds.

Before the application of electricity, only two compounds were found suitable for reduction to the metallic state. Alumina itself is so refractory that it cannot be melted save by the oxy-hydrogen blowpipe, or the electric arc, and except in the molten state it is not susceptible of decomposition by any chemical reagent. Deville first selected the chloride as his raw material, but observing it to be volatile and extremely deliquescent, he soon substituted in its place a double chloride of aluminium and sodium. Early in 1855 Percy suggested that cryolite should be more convenient, as it was a natural mineral and might not require purification, and at the end of March in that year, Faraday exhibited before the Royal Institution samples of the metal reduced from its fluoride by Dick and Smith. Rose also carried out experiments on the decomposition of cryolite, and expressed an opinion that it was the best of all compounds for reduction; but, finding the yield of metal to be low, receiving a report of the difficulties experienced in mining the ore, and fearing to cripple his new industry by basing it upon the employment of a mineral of such uncertain supply, Deville decided to keep to his chlorides. With the advent of the dynamo, the position of affairs was wholly changed. The first successful idea of using electricity depended on the enormous heating powers of the arc. The infusibility of alumina was no longer prohibitive, for the molten oxide is easily reduced by carbon. Nevertheless, it was found impracticable to smelt alumina electrically except in presence of copper, so that the Cowles furnace yielded, not the pure metal, but an alloy. So long as the metal was principally regarded as a necessary ingredient of aluminium-bronze, the Cowles process was popular, but when the advantages of aluminium itself became more apparent, there arose a fresh demand for some cheap method of obtaining it unalloyed. It was soon discovered that the faculty of inducing dissociation possessed by the current might now be utilized with some hope of pecuniary success, but as electrolytic currents are of lower voltage than those required in electric furnaces, molten alumina again became impossible. Many metals, of which copper, silver, and nickel are types, can be readily won or purified by the electrolysis of aqueous solutions, and theoretically it may be feasible to treat aluminium in an identical manner. In practice, however,

it cannot be thrown down electrolytically with a dissimilar anode so as to win the metal, and certain difficulties are still met with in the analogous operation of plating by means of a similar anode. Of the simple compounds, only the fluoride is amenable to electrolysis in the fused state, since the chloride begins to volatilize below its melting-point, and the latter is only 5° below its boiling-point. Cryolite is not a safe body to electrolyse, because the minimum voltage needed to break up the aluminium fluoride is 4.0, whereas the sodium fluoride requires only 4.7 volts; if, therefore, the current rises in tension, the alkali is reduced, and the final product consists of an alloy with sodium. The corresponding double chloride is a far better material; first, because it melts at about $180^\circ C.$, and does not volatilize below a red heat, and second, because the voltage of aluminium chloride is 2.3 and that of sodium chloride 4.3, so that there is a much wider margin of safety to cover irregularities in the electric pressure. It has been found, however, that molten cryolite and the analogous double fluoride represented by the formula $Al_2F_6 \cdot 2NaF$ are very efficient solvents of alumina, and that these solutions can be easily electrolysed at about $800^\circ C.$ by means of a current that completely decomposes the oxide but leaves the haloid salts unaffected. Molten cryolite dissolves roughly 30 per cent. of its weight of pure alumina, so that when ready for treatment the solution contains about the same proportion of what may be termed "available" aluminium as does the fused double chloride of aluminium and sodium. The advantages lie with the oxide because of its easier preparation. Alumina dissolves readily enough in aqueous hydrochloric acid to yield a solution of the chloride, but neither this solution, nor that containing sodium chloride, can be evaporated to dryness without decomposition. To obtain the anhydrous single or double chloride, alumina must be ignited with carbon in a current of chlorine, and to exclude iron from the finished metal, either the alumina must be pure, or the chloride be submitted to purification. Thus preparation of a chlorine compound suited for electrolysis becomes more costly and more troublesome than that of the oxide, and in addition four times as much raw material must be handled.

At different times propositions have been made by Bucherer, Blackmore, and others, to win the metal from its sulphide. This compound possesses a heat of formation so much lower that electrically it needs but a voltage of 0.9 to decompose it, and it is easily soluble in the fused sulphides of the alkali metals. It can also be reduced metallurgically by the action of molten iron. Various considerations, however, tend to show that there cannot be so much advantage in employing it as would appear at first sight. As it is easier to reduce than any other compound, so it is more difficult to produce. Therefore while less energy is absorbed in its final reduction, more is needed in its initial preparation, and it is questionable whether the economy possible in the second stage would not be neutralized by the greater cost of the first stage in the whole operation of winning the metal from bauxite with the sulphide as the intermediary.

The Deville process as gradually elaborated between 1855 and 1859 exhibited three distinct phases:—Production of metallic sodium, formation of the pure double chloride of sodium and aluminium, and preparation of the metal by the **Chemical reduction.** interaction of the two former substances. To produce the alkali metal, a calcined mixture of sodium carbonate, coal, and chalk was strongly ignited in flat retorts made of boiler-plate; the sodium distilled over into condensers, and was preserved under heavy petroleum. In order to prepare pure alumina, bauxite and sodium carbonate were heated in a furnace until the reaction was complete; the product was then extracted with water to dissolve the sodium aluminate, the solution treated with carbon dioxide, and the precipitate removed and dried. This purified oxide, mixed with sodium chloride and coal tar, was carbonized at a red heat, and ignited in a current of dry chlorine as long as vapours of the double chloride were given off, these being condensed in suitable chambers. For the production of the final aluminium, 100 parts of the chloride and 45 parts of cryolite to serve as a flux were powdered together, and mixed with 35 parts of sodium cut into small pieces. The whole was thrown in several portions on to the hearth of a furnace previously heated to low redness, and was stirred at intervals for three hours. At length when the furnace was tapped a white slag was drawn off from the top, and the liquid metal beneath was received into a ladle and poured into cast-iron moulds. The process was worked out by Deville in his laboratory at the École Normale in Paris. Early in 1855 he conducted large-scale experiments at Javel in a factory lent him for the purpose, where he produced sufficient to show at the French Exhibition of 1855. In the spring of 1856 a complete plant was erected at La Glacière, a suburb of Paris, but becoming a nuisance to the neighbours, it was removed to Nanterre in the following year. Later it was again transferred to Salindres, where the manufacture was continued by Messrs. Pechiney till, after Deville's death in 1881, the advent of the present electrolytic process rendered it no longer profitable. Deville received much encouragement and

pecuniary assistance from the French Academy, and also from the hands of Napoleon III., who, impressed with an aluminium medal struck in his honour, and with a baby-rattle presented to the infant Prince Imperial, conceived the idea of furnishing his Cuirassiers with aluminium armour and helmets. For over a year the Emperor defrayed Deville's expenses, and although the latter did not find it possible to gratify his patron's military aspirations, yet Napoleon III.'s generosity in assisting scientific research has borne much fruit both in the western and eastern hemispheres.

When Deville quitted the Javel works, two brothers named Tissier, formerly his assistants, who had devised an improved sodium furnace and had acquired a thorough knowledge of their leader's experiments, also left, and erected a factory at Amfreville, near Rouen, to work the cryolite process. This need not be described at length. It consisted simply in reducing cryolite with metallic sodium exactly as in Deville's chloride method, and it was claimed to possess various mythical advantages over its rival. Two grave disadvantages were soon obvious—the limited supply of ore, and, what was even more serious, the large proportion of silicon in the reduced metal. The Amfreville works existed some eight or ten years, but achieved no permanent prosperity. In 1858 or 1859 a small factory, the first in England, was built by F. W. Gerhard at Battersea, who also employed cryolite, made his own sodium, and was able to sell the product at 3s. 9d. per oz. This enterprise only lasted about four years. Between 1860 and 1874 Messrs Bell Brothers manufactured the metal at Washington, near Newcastle, under Deville's supervision, producing nearly 2 cwt. per year. They took part in the International Exhibition of 1862, quoting a price of 40s. per lb troy.

In 1881 Webster patented an improved process for making alumina, and the following year he organized the Aluminium Crown Metal Co. of Hollywood to exploit it in conjunction with Deville's method of reduction. Potash-alum and pitch were calcined together, and the mass was treated with hydrochloric acid; charcoal and water to form a paste were next added, and the whole was dried and ignited in a current of air and steam. The residue, consisting of alumina and potassium sulphate, was leached with water to separate the insoluble matter which was dried as usual. All the by-products, potassium sulphate, sulphur, and aluminate of iron, were capable of recovery, and were claimed to reduce the cost of the oxide materially. From this alumina the double chloride was prepared in essentially the same manner as practised at Salindres, but sundry economies accrued in the process owing to the larger scale of working and to the adoption of Weldon's method of regenerating the spent chlorine liquors. In 1886 Castner's sodium patents appeared, and The Aluminium Co. of Oldbury was promoted to combine the advantages of Webster's alumina and Castner's sodium. Castner had long been interested in aluminium, and was desirous of lowering its price. Seeing that sodium was the only possible reducing agent, he set himself to cheapen its cost, and deliberately rejecting sodium carbonate for the more expensive sodium hydroxide (caustic soda), and replacing carbon by a mixture of iron and carbon—the so-called carbide of iron—he invented the highly scientific method of winning the alkali metal which has remained in existence almost to the present day. In 1872 sodium prepared by Deville's process cost about 4s. per lb, the greater part of the expense being due to the constant failure of the retorts; in 1887 Castner's sodium cost less than 1s. per lb, for his cast-iron pots survived 125 distillations.

In the same year Grabau patented a method of reducing the simple fluoride of aluminium with sodium, and his process was operated at Trotha in Germany. It was distinguished by the unusual purity of the metal obtained, some of his samples containing 99.5 to 99.8 per cent. In 1888 the Alliance Aluminium Co. was organized to work certain patents taken out during the previous year by Dr Netto, Capt. Cunningham, and Mr Forster for winning the metal from cryolite by means of sodium, but these were only modifications in detail of the processes already described. This company erected plant in London, Hebburn, and Wallsend, and by 1889 were selling the metal at 11s. to 15s. per lb. The Aluminium Company's price in 1888 was 20s. per lb and the output about 250 lb per day. In 1889 the price was 16s., but by 1891 the electricians commenced to offer metal at 4s. per lb and aluminium reduced with sodium became a thing of the past.

About 1879 dynamos began to be introduced into metallurgical practice, and from that date onwards numerous schemes for utilizing this cheaper form of energy were brought before the public. The first electrical method worthy of notice is that patented by Messrs E. H. and A. H. Cowles in 1885, which was worked both at Lockport, New York State, and at Milton, Staffordshire. The furnace consisted of a flat rectangular firebrick box, packed with a layer of finely powdered charcoal 2 inches thick. Through stuffing-boxes at the ends passed the two electrodes, made after the fashion of arc-light carbons, and capable of being approached together according to the requirements of the operation. The central space of the furnace was filled with a

mixture of corundum, coarsely powdered charcoal, and copper; and an iron lid lined with firebrick was luted in its place to exclude air. The charge was reduced by means of a 50-volt current from a 300-kilowatt dynamo, which was passed through the furnace for 1½ hours till decomposition was complete. About 100 lb of bronze, containing from 15 to 20 lb of aluminium, were obtained from each run, the yield of the alloy being reported at about 1 lb per 18 e.h.p.-hours. The composition of the alloys thus produced could not be predetermined with exactitude; each batch was therefore analysed, a number of them were bulked together, or mixed with copper in the necessary proportion, and melted in crucibles to give merchantable bronzes containing between 1½ and 10 per cent. of aluminium. Although the copper took no part in the reaction, its employment was found indispensable, as otherwise the aluminium partly volatilized, and partly combined with the carbon to form a carbide. It was also necessary to give the fine charcoal a thin coating of calcium oxide by soaking it in lime-water, for the temperature was so high that unless it was thus protected it was gradually converted into graphite, losing its insulating power and diffusing the current through the lining and walls of the furnace. That this process did not depend upon electrolysis, but was simply an instance of electrical smelting, or the decomposition of an oxide by means of carbon at the temperature of the electric arc, is shown by the fact that the Cowles furnace would work with an alternating current.

In 1883 Grätzel patented a useless electrolytic process with fused cryolite or the double chloride as the raw material, and in 1886 Kleiner propounded a cryolite method which was worked for a time by the Aluminium Syndicate at Tyldesley near Manchester, but was abandoned in 1890. In 1887 Minet took out patents for electrolyzing a mixture of sodium chloride with aluminium fluoride, or with natural or artificial cryolite. The operation was continuous, the metal being regularly run off from the bottom of the bath, while fresh alumina and fluoride were added as required. The process exhibited several disadvantages; the electrolyte had to be kept constant in composition lest either fluorine vapours should be evolved or sodium thrown down, and the raw materials had accordingly to be prepared in a pure state. After prolonged experiments in a factory owned by Messrs Bernard Frères at St Michel in Savoy, Minet's process was given up, and at the close of the 19th century the Héroult-Hall method was alone being employed in the manufacture of aluminium throughout the world.

The original Deville process for obtaining pure alumina from bauxite was greatly simplified in 1889 by Bayer, whose most recent patents are being exploited at Larne in Ireland. Crude bauxite is ground, lightly calcined to destroy organic matter, and agitated under a pressure of 70 or 80 lb per square inch with a solution of sodium hydroxide having the specific gravity 1.45. After two or three hours the liquid is diluted till its density falls to 1.23, when it is passed through filter-presses to remove the insoluble ferric oxide and silica. The solution of sodium aluminate, containing aluminium oxide and sodium oxide in the molecular proportion of 6 to 1, is next agitated for thirty-six hours with a small quantity of hydrated alumina previously obtained, which causes the liquor to decompose, and some 70 per cent. of the aluminium hydroxide to be thrown down. The filtrate, now containing roughly two molecules of alumina to one of soda, is concentrated to the original gravity of 1.45, and employed instead of fresh caustic for the attack of more bauxite; the precipitate is then collected, washed till free from soda, dried, and ignited at about 1000° C. to convert it into a crystalline oxide which is less hygroscopic than the former amorphous variety.

The process of manufacture which now remains to be described was patented during 1886 and 1887 in the name of C. M. Hall in America, in that of P. V. L. Héroult in England and France. It would be idle to discuss to whom the credit of first imagining the method rightfully belongs, for probably this is only one of the many occasions when new ideas have been born in several brains at the same time. Hall, however, at once realized that his aim should be to win aluminium itself in an electrically warmed bath; for a while Héroult seemed undecided between the pure metal and an alloy, between internal and external heating. By 1888 Hall was at work on a commercial scale at Pittsburg, reducing German alumina; in 1891 the plant was removed to New Kensington for economy in fuel, and was gradually enlarged to 1500 h.p.; in 1894 a factory of 5000 h.p. driven by water was erected at Niagara Falls. In 1890 also the Hall process operated by steam power was installed at Patricroft, Lancashire, where the plant had a capacity of 300 lb per day, but by 1894 the turbines of the Swiss and French works ruined the enterprise. About 1897 the Bernard factory at St Michel passed into the hands of Messrs Pechiney, the machinery soon being increased to 3000 h.p., and there, under the control of a firm that has been concerned in the industry almost from its inception, aluminium is being manufactured by the Hall process. In July 1888 the Société Métallurgique Suisse erected plant driven by a 500 h.p. turbine to carry out Héroult's alloy process, and at

the end of that year the Allgemeine Elektrizitäts Gesellschaft united with the Swiss firm in organizing the Aluminium Industrie Actien Gesellschaft of Neuhausen to manufacture the metal on a larger scale. Héroult and Kiliiani then reverted to the plan of winning the metal alone, and gradually the alloy process was abandoned. At present (1900) about 4000 h.p. obtained from the Rhine are employed at Neuhausen, and about 2000 h.p. at Rheinfelden, while some 3000 h.p. are similarly used by the Société Electro-Métallurgique Française of La Praz near Modane. In 1895 the British Aluminium Company was founded to mine bauxite and manufacture alumina in Ireland, to prepare the necessary electrodes at Greenock, to reduce the aluminium at Foyers, and to refine and work up the metal into marketable shapes at the old Milton factory of the Cowles Syndicate, remodelled to suit modern requirements.

The river Foyers in Inverness-shire, which empties itself into Loch Ness, makes a total descent of 400 feet during the last $\frac{1}{4}$ mile of its course, and forms two cascades 40 feet and 165 feet high respectively. From a point some distance above the upper fall an 8-foot tunnel has been drilled through the solid rock, bringing the water at a high level to the brow of the hill that slopes down to the loch, which it descends in steel tubes to drive the turbines at the bottom. Lest the natural river should fail in times of drought, water-rights over some 100 square miles of Inverness-shire have been acquired, and a masonry dam has been built across the southern end of the mountain valley (700 feet high) that contained Lochs Faraline and Garth, so as to raise the water level and form one vast reservoir 5 miles long by $\frac{3}{4}$ mile wide holding 4000 million gallons—sufficient without any rainfall to propel the machinery for 100 days. By the end of 1899 plant equal to 7000 h.p. had been installed, some of it, however, being employed in the manufacture of calcium carbide. Each dynamo is carried on the same vertical shaft with its turbine, and runs at a speed of 150 revolutions per minute, developing 700 e.h.p., and giving a current of some 8000 amperes at 60 volts.

The Héroult cell consists of a square iron or steel box lined with carbon rammed and baked into a solid mass; at the bottom is a cast-iron plate connected with the negative pole of the dynamo, but the actual working cathode is undoubtedly the layer of already reduced and molten metal that lies in the bath. The anode is formed of a bundle of carbon rods suspended from overhead so as to be capable of vertical adjustment. The cell is filled up with cryolite, and the current is turned on till this is melted; then the pure powdered alumina is fed in continuously as long as the operation proceeds. The current is supplied at a tension of 3 to 5 volts per cell, passing through 10 or 12 in series; and it performs two distinct functions—(1) it overcomes the chemical affinity of the aluminium oxide; (2) it overcomes the resistance of the electrolyte, heating the liquid at the same time. As a part of the voltage is consumed in the latter duty, only the residue can be converted into chemical work, and as the theoretical voltage of the aluminium fluoride in the cryolite is 4.0, provided the bath is kept properly supplied with alumina, the fluorides are not attacked. It follows, therefore, except for mechanical losses, that one charge of cryolite lasts indefinitely, that the sodium and other impurities in it are not liable to contaminate the product, and that only the alumina itself need be carefully purified. The operation is essentially a dissociation of alumina into aluminium, which collects at the cathode, and into oxygen, which combines with the anodes to form carbon monoxide, the latter escaping and being burnt to carbon dioxide outside. Theoretically 36 parts by weight of carbon are oxidized in the production of 54 parts of aluminium; practically the anodes waste at the same rate at which metal is deposited. The current density is about 700 amperes per square foot of cathode surface, and the number of rods in the anode is such that each delivers 6 or 7 amperes per square inch of cross-sectional area. The working temperature lies between 750° and 850° C., and the actual yield is 1 lb of metal per 12 e.h.p. hours. The bath is heated internally with the current rather than by means of external fuel, because this arrangement permits the vessel itself to be kept comparatively cool; if it were fired from without, it would be hotter than the electrolyte, and no material suitable for the construction of the cell is competent to withstand the attack of nascent aluminium at high temperatures. Aluminium is so light that it is a matter requiring some ingenuity to select a convenient solvent through which it shall sink quickly, for if it does not sink, it short-circuits the electrolyte. The molten metal has a specific gravity of 2.54, that of molten cryolite saturated with alumina is 2.35, and that of the fluoride $Al_2F_6 \cdot 2NaF$ saturated with alumina 1.97. The latter therefore appears the better material, and was originally preferred by Hall; cryolite, however, dissolves more alumina, and has been finally adopted by both inventors.

Aluminium is a white metal with a characteristic tint which most nearly resembles that of tin; when impure, or

after prolonged exposure to air, it has a slight violet shade. Its atomic weight is 27 (26.77, $H = 1$, according to J. Thomsen). It is trivalent. The specific gravity *Properties.* of cast metal is 2.583, and of rolled 2.688 at 4° C. It melts at 626° C. (freezing-point 654.5°, Heycock and Neville). It is the third most malleable and sixth most ductile metal, yielding sheets 0.000025 inch in thickness, and wires 0.004 inch in diameter. When quite pure it is somewhat harder than tin, and its hardness is considerably increased by rolling. It is not magnetic. It stands near the positive end of the list of elements arranged in electromotive series, being exceeded only by the alkalis and metals of the alkaline earths; it therefore combines eagerly, under suitable conditions, with oxygen and chlorine. Its coefficient of linear expansion by heat is 0.0000222 (Richards) or 0.0000231 (Roberts-Austen) per 1° C. Its mean specific heat between 0° and 100° is 0.227, and its latent heat of fusion 100 calories (Richards). Only silver, copper, and gold surpass it as conductors of heat, its value being 31.33 ($Ag = 100$, Roberts-Austen). Its electrical conductivity, determined on 99.6 per cent. metal, is 60.5 per cent. that of copper for equal volumes, or double that of copper for equal weights, and when chemically pure it exhibits a somewhat higher relative efficiency. The average strength of 98 per cent. metal is approximately shown by the following table:—

	Elastic Limit, tons per square inch.	Ultimate Strength, tons per square inch.	Reduction of Area per cent.
Cast	3	7	15
Sheet	5 $\frac{1}{2}$	11	35
Bars	6 $\frac{1}{2}$	12	40
Wire	7-13	13-29	60

Weight for weight, therefore, aluminium is only exceeded in tensile strength by the best cast steel, and its own alloy, aluminium bronze. An absolutely clean surface becomes tarnished in damp air, an almost invisible coating of oxide being produced, just as happens with zinc; but this film is very permanent and prevents further attack. Exposure to air and rain also causes slight corrosion, but to nothing like the same extent as occurs with iron, copper, or brass. Commercial electrolytic aluminium of the best quality contains as the average of a large number of tests, 0.48 per cent. of silicon and 0.46 per cent. of iron, the residue being essentially aluminium itself. The metal in mass is not affected by hot or cold water, the foil is very slowly oxidized, while the amalgam decomposes rapidly. Sulphuretted hydrogen has no action upon it, therefore articles made of it are not blackened in foggy weather or in rooms where crude coal gas is burnt. To inorganic acids, except hydrochloric, it is highly resistant, ranking well with tin in this respect; but alkalis dissolve it quickly. Organic acids such as vinegar, common salt, the natural ingredients of food, and the various extraneous substances used as food preservatives, alone, or mixed together, dissolve traces of it if boiled for any length of time in a chemically clean vessel; but when aluminium utensils are submitted to the ordinary routine of the kitchen, being used to heat or cook milk, coffee, vegetables, meat, and even fruit, and are also cleaned frequently in the usual fashion, no appreciable quantity of metal passes into the food. Moreover, did it do so, the action upon the human system would be infinitely less harmful than similar doses of copper or of lead.

The highly electro-positive character of aluminium is most important. At elevated temperatures the metal decomposes nearly all other metallic oxides, wherefore it is most serviceable as a metallurgical reagent. In the casting of iron, steel, and brass, the addition of a trifling

proportion (0.005 per cent.) removes oxide, and renders the molten metal more fluid, causing the finished products to be more homogeneous, free from blow-holes, and solid all through. On the other hand, its electro-positive nature necessitates some care in its utilization. If it be exposed to damp, to sea-water, or to corrosive influences of any kind in contact with another metal, or if it be mixed with another metal so as to form an alloy which is not a true chemical compound, the other metal being highly negative to it, powerful galvanic action will be set up, and the structure will quickly deteriorate. This explains the failure of boats built of commercially pure aluminium which have been put together with iron or copper rivets, and the decay of other boats built of a light alloy, in which the alloying metal (copper) has been injudiciously chosen. It also explains why aluminium is so difficult to join with low-temperature solders, for these mostly contain a large proportion of lead. This disadvantage, however, is often overestimated, since in most cases other means of uniting two pieces are available.

The metal produces an enormous number of useful alloys, some of which, containing only 1 or 2 per cent.

Alloys. of other metals, combine the lightness of aluminium itself with far greater hardness and strength. Some with 90 to 99 per cent. of other metals exhibit the general properties of those metals conspicuously improved. Among the heavy alloys, the aluminium bronzes (Cu, 90-97.5 per cent.; Al, 2.5-10 per cent.) occupy the most important position, showing mean tensile strengths increasing from 20 to 41 tons per square inch as the percentage of aluminium rises, and all strongly resisting corrosion in air or sea-water. The light copper alloys, in which the proportions just given are practically reversed, are of considerably less utility, for although they are fairly strong, they lack power to resist galvanic action. This subject is far from being exhausted, and it is not improbable that the alloy-producing capacity of aluminium may eventually prove its most valuable characteristic. In the meantime, ternary light alloys appear the most satisfactory, and tungsten and copper, or tungsten and nickel, seem to be the best substances to add.

The uses of aluminium are too numerous to mention. Probably the widest field is still in the purification of iron and steel. To the general public it appeals

Uses. most strongly as a material for constructing cooking utensils. It is not brittle like porcelain and cast iron, not poisonous like lead-glazed earthenware and untinned copper, has no enamel to chip off like steel, does not rust and wear out like cheap tinplate, and weighs but a fraction of other substances. It is largely replacing brass and copper in all departments of industry—especially where dead weight has to be moved about, and lightness is synonymous with economy—for instance, in bed-plates for torpedo-boat engines, internal fittings for ships instead of wood, complete boats for portage, motor-car parts, and boiling-pans for confectionery and in chemical works. The British Admiralty employ it to save weight in the Navy, and the Continental war-offices equip their soldiers with it wherever possible. As a substitute for Solenhofen stone it is used in a modified form of lithography, which can be performed on rotary printing-machines at a high speed. With the increasing price of copper, it is coming into vogue as an electrical conductor for uncovered mains; it is found that an aluminium wire 0.126 inch in diameter will carry as much current as a copper wire 0.100 inch in diameter, while the former weighs about 79 lb and the latter 162 lb per mile. Assuming the materials to be of equal tensile strength per unit of area—hard-drawn copper is stronger, but has a lower conductivity—the adoption of aluminium thus leads to a

reduction of 52 per cent. in the weight, a gain of 60 per cent. in the strength, and an increase of 26 per cent. in the diameter of the conductor; a saving in cost of poles is also effected. At present prices (1900) it is already cheaper than copper per unit of electric current conveyed; but when insulation is necessary, the smaller size of the copper wire renders it more economical. Aluminium conductors have been employed on heavy work in many places outside England, notably for a 30,000 volt current in Washington Territory, U.S.A., which is transmitted a distance of over 30 miles, and similar developments are proceeding in England, the earliest being at Northallerton. For telegraphy and telephony, aluminium conductors are in frequent demand, and give perfect satisfaction. Difficulties were at first encountered in making the necessary joints, but they have been largely overcome by practice and experience.

Two points connected with this metal are of sufficient moment to demand a few words by way of conclusion. Its extraordinary lightness forms its chief claim to general adoption, yet is apt to cause mistakes when its price is mentioned. It is the weight of a mass of metal which governs its financial value; its industrial value, in the vast majority of cases, depends on the volume of that mass. Provided it be rigid, the bed-plate of an engine is no better for weighing 30 cwt. than for weighing 10 cwt. A saucepan is required to have a certain diameter and a certain depth in order that it shall hold a certain bulk of liquid: its weight is merely an encumbrance. Copper being $3\frac{1}{3}$ times as heavy as aluminium, whenever the latter costs less than $3\frac{1}{3}$ times as much as copper it is actually cheaper. It must be remembered, too, that electrolytic aluminium has only been known during the last decade of the 19th century. Samples dating from the old sodium days are still in existence, and when they exhibit unpleasant properties the defect is often ascribed to the metal instead of to the process by which it was won. Much has yet to be learnt about the practical qualities of the electrolytic product, and although every day's experience serves to place the metal in a firmer industrial position, a final verdict can only be passed after the lapse of time. The individual and collective influence of the several impurities which occur in the product of the Héroult cell is still to seek, and the importance of this inquiry will be seen when we consider that if cast iron, wrought iron, and steel, the three totally distinct metals included in the generic name of "iron"—which are only distinguished one from another chemically by minute differences in the proportion of certain non-metallic ingredients—had only been in use for some dozen years, attempts might occasionally be made to forge cast iron, or to employ wrought iron in the manufacture of edge-tools.

(E. J. R.)

Alva, a police burgh and (woollen) manufacturing town of Clackmannanshire (transferred from Stirlingshire, 1891), Scotland, 7 miles E. of Stirling, the terminus of a branch of the North British Railway. Population (1881), 4961; (1891), 5225; (1901), 4624.

Alverstone, Richard Everard Webster, 1st BARON, Lord Chief Justice of England (1842—), was born 22nd December 1842, being the second son of Thomas Webster, Q.C. He was educated at King's College and Charterhouse schools, and Trinity College, Cambridge; was called to the bar in 1868, and became Q.C. only ten years afterwards. His practice was chiefly in commercial, railway, and patent cases until (June 1885) he was appointed attorney-general in the Conservative Government in the exceptional circumstances of never having been solicitor-general, and not at the time occupying a seat in parliament. He was elected for Launceston in the fol-

lowing month, and in November exchanged this seat for the Isle of Wight, which he continued to represent until his elevation to the House of Lords. Except under the brief Gladstone administration of 1886, and the Gladstone-Rosebery Cabinet of 1892-95, Sir Richard Webster was attorney-general from 1885 to 1899. In 1890 he was leading counsel for the *Times* in the Parnell inquiry; in 1893 he represented Great Britain in the Bering Sea arbitration; and in 1898 he discharged the same function in the matter of the boundary between British Guiana and Venezuela. He was well known as an athlete in his earlier years, having represented his university as a runner, and his interest in cricket and foot-racing was kept up in later life. In the House of Commons, and outside it, he was throughout his political career prominently associated with Church work; and though he had no claim to a reputation for eloquence, his speeches were distinguished for the more solid qualities of gravity and earnestness. In 1899 he succeeded Sir Nathaniel Lindley as Master of the Rolls, at the same time being raised to the peerage as Baron Alverstone, and in October of the same year he was elevated to the office of Lord Chief Justice upon the death of Lord Russell of Killowen.

Alwár, or Ulwar, a native state of India, in the Rajputana agency. Area, 3051 square miles; population (1881), 682,926; (1891), 767,786—average density, 252 persons per square mile; (1901), 828,888, showing an increase of 8 per cent. When compared with a heavy decrease elsewhere throughout Rajputana, this increase may be attributed to the successful administration of famine relief, under British officials. The gross revenue in 1896-97 was Rs.27,88,410, of which Rs.20,48,000 was derived from land, Rs.1,25,000 from salt, and Rs.1,85,000 from interest. The expenditure included Rs.3,59,000 for public works, Rs.5,10,706 for imperial service troops, Rs.3,87,602 for irregular forces, Rs.1,53,000 for palace, and Rs.3,13,000 for stables, &c. There was a balance of Rs.65,53,000, mostly invested in government securities. The present Maharaja, Jai Singh, who succeeded in 1892, was educated at the Mayo College, where he excelled both in sports and in knowledge of English. Alwár was the first native state to accept a currency struck at the Calcutta mint, of the same weight and assay as the imperial rupee, with the head of the British Sovereign on the obverse. Imperial service troops are maintained, consisting of both cavalry and infantry, with transport. The state is traversed by the Delhi branch of the Rajputana railway. A settlement of the land revenue is being carried out by an English civilian.

The city of ALWÁR is situated in 27° 34' lat. N. and 76° 38' E. long.; railway station on the Rajputana line, 98 miles from Delhi. Population (1881), 49,876; (1891), 52,398; (1901), 56,740, showing a steady increase. It stands in a valley overhung by a fortress 1000 feet above. It is surrounded by a rampart and moat, with five gates, and contains fine palaces, temples, and tombs. The water-supply is brought from a lake 9 miles distant. It has a high school, affiliated to the Allahabad university; and a school for the sons of nobles, founded to commemorate the Diamond Jubilee of Queen Victoria. The Lady Dufferin hospital is under the charge of an English lady doctor, with two female assistants.

Amakusa, an island belonging to Japan, 36½ miles long and 13½ wide, situated in 32° 20' N. lat. and 131° E. long., on the west of the province of Higo, from which it is separated by the Yatsushiro-kai. It has no high mountains, but its surface being very hilly—four of the peaks rise to a height of over 1500 feet—the natives resort to the terrace system of cultivation with remarkable success. A number of the heads of the Christians exe-

cuted in connection with the Shimabara rebellion in the 17th century were buried in this island. Amakusa produces fine kaolin, which was largely used in former times by the potters of Hirado and Satsuma.

Amalfi, a town and archiepiscopal see of Campania, province of Salerno, Italy, on the N. coast of the Gulf of Salerno, 13 miles W. by S. from Salerno. This part of the coast produces first-class lemons. Macaroni is manufactured. A serious landslip choked up the harbour in January 1900. Population, 4792 (1881); 7329 (1901).

Amara, a town of Asiatic Turkey, in the Basra viláyet, on the left bank of the Tigris, connected with the right bank by a bridge of boats. It is the chief town of a rich district and exports grain and dates. Population, 9500.

Amarapura, formerly capital of Burma, now a subdivision of the Mandalay district, with an area of 304 square miles and a population of 62,310. The old city of Amarapura is in a state of utter ruin. The Burmans know it as Myohrung, "the old city." It is a station on the Rangoon-Mandalay railway, and is the junction for the line to Maymyo and the Kunlóng ferry, and for the Sagaing-Myitkyina railway. The group of villages called Amarapura by Europeans is known to the Burmans as Taung-myo, "the southern city," as distinguished from Mandalay, the Myauk-myo, or "northern city," 3 miles distant. Amarapura, though little more than a century old and abandoned so recently as 1860, is stamped with the desolation of ages, so completely have the climate and vandalism changed its aspect. It contains many pagodas.

Amásia, the chief town of a district in the Sivas viláyet in Asia Minor, and an important trade centre on the Samsún-Sivas road. It was one of the chief towns of the kingdom of Trebizond, and was much favoured by the early Osmanli sultans, one of whom, Selim I., was born there. Amásia has extensive orchards and fruit gardens; and there are steam flour-mills. Wheat, flour, and silk are exported. In 1895 there was a massacre of Armenians. Population, 30,000 (Moslems, 20,000, of whom one-third are Shíás; Christians, 10,000).

Amazon.—The river Amazon, the largest in the world, has a drainage area of 2,722,000 square miles, if the Tocantins be included in its basin. It drains four-tenths of South America, and it gathers its waters from 5° N. to 20° S. latitude. Its most remote sources are found on the inter-Andean plateau, but a short distance from the Pacific Ocean; and, after a course of about 4000 miles through the interior of Peru and across Brazil, it enters the Atlantic Ocean on the equator. It is generally accepted by geographers that the Marañon, or Upper Amazon, rises in the little lake, Lauricocha, in 10° 30' S. latitude and 100 miles N.N.E. of Lima. They appear to have followed the account given by Padre Fritz, which has since been found incorrect. According to Antonio Raimondi, it is the Rio de Nupe branch of the small stream which issues from the lake that has the longer course and the greater volume of water. The Nupe rises in the Cordillera de Huayhuath, and is the true source of the Marañon. There is a difference among geographers as to where the Marañon ends and the Amazon commences, or whether both names apply to the same river. The Pongo de Manseriche, at the base of the Andes, and the head of useful navigation, seems to be the natural terminus of the Marañon; and an examination of the hydrographic conditions of the great valley makes the convenience and accuracy of this apparent. Raimondi terminates the Marañon at the

mouth of the Ucayali, Reclus the same, both following the missionary fathers of the colonial period. M. de la Condamine uses "Amazon" and "Marañon" indiscriminately, and considers them one and the same. Smith and Lowe give the mouth of the Javary as the eastern limit, as does d'Orbigny. Wolf, apparently uncertain, carries the "Marañon or Amazon" to the Peruvian frontier of Brazil, at Tabatinga. Other travellers and explorers contribute to the confusion. This probably arises from the rivalry of the Spaniards and Portuguese. The former accepted the name Marañon, in Peru, and as the missionaries penetrated the valley they extended the name until they reached the Ucayali; while, as the Portuguese ascended the Amazon, they carried its name to the extent of their explorations. Beginning with the lower

river we propose to notice, first, the great affluents which go to swell the volume of the main stream.

Tributaries.

The TOCANTINS is not really a branch of the Amazon, although usually so considered. It is the great central fluvial artery of Brazil, running from south to north for a distance of about 1500 miles. It rises in the mountainous district known as the Pyreneos; but its more ambitious western affluent, the Araguay, has its extreme southern headwaters on the slopes of the Serra Cayapó, and flows a distance of 1080 miles before its junction with the parent stream, which it appears almost to equal in volume. Besides its main tributary, the Rio das Mortes, it has twenty smaller branches, offering many miles of canoe navigation.

B. V. Darbishire & O. J. R. Howarth

Oxford 1901

THE AMAZON AND ITS TRIBUTARIES.

In finding its way to the lowlands, it breaks frequently into falls and rapids, or winds violently through rocky gorges, until, at a point about 100 miles above its junction with the Tocantins, it saws its way across a rocky dyke, for 12 miles, in roaring cataracts. The tributaries of the Tocantins, called the Maranhão and Parana-tinga, collect an immense volume of water from the highlands which surround them, especially on the south and south-east. Between the latter and the confluence with the Araguay, the Tocantins is occasionally obstructed by rocky barriers which cross it almost at a right angle. Through these, the river carves its channel, broken into cataracts and rapids, or *cachoeiras*, as they are called throughout Brazil. Its lowest one, the Itaboca cataract, is about 130 miles above its estuarine port of Cameté, for which distance the river is navigable; but above that it is useless as a commercial avenue, except for laborious and very costly transportation. The flat, broad valleys, composed of sand and clay, of both the Tocantins and its Araguay branch, are overlooked by steep bluffs. They are the margins of the great sandstone plateaux, from 1000 to 2000 feet elevation above sea-level, through which the

river have eroded their deep beds. Around the estuary of the Tocantins the great plateau has disappeared, to give place to a part of the forest-covered, half-submerged alluvial plain which extends far to the north-east and west. The Pará river, generally called one of the mouths of the Amazon, is only the lower reach of the Tocantins. If any portion of the waters of the Amazon runs round the southern side of the large island of Marajo into the river Pará, it is only through tortuous, natural canals, which are in no sense outflow channels of the Amazon.

The XINGÚ, the next large river west of the Tocantins, is a true tributary of the Amazon. It was but little known until it was explored in 1884-87 by von den Steinen, from Cuyabá. Travelling east, 240 miles, he found the river Tamitatoaba, 180 feet wide, flowing from a lake 25 miles in diameter. He descended this torrential stream to the river Romero, 1300 feet wide, entering from the west, which receives the river Colisú. These three streams form the Xingú, or Parana-xingú, which, from 73 miles lower down, bounds along a succession of rapids for 400 miles. A little above the head of navigation, 105 miles from its mouth, the river makes a bend to

the east to find its way across a rocky barrier. Here is the great cataract of Itamaracá, which rushes down an inclined plane for three miles and then gives a final leap, called the Fall of Itamaracá. Near its mouth, the Xingú expands into an immense lake, and its waters then mingle with those of the Amazon through a labyrinth of *caños* (natural canals), winding in countless directions through a wooded archipelago.

The TAPAJOS, running through a humid, hot, and unhealthy valley, pours into the Amazon 500 miles above Pará, and is about 1200 miles long. It rises on the lofty Brazilian plateau near Diamantino, in 14° 25' S. lat. Near this place, a number of streams unite to form the river Arinos, which, at latitude 10° 25', joins the Juruena, to form the "Alto Tapajos," so called as low down as the Rio Manoel, entering from the east. Thence, to Santarem, the stream is known as the Tapajos. The lower Arinos, the Alto Tapajos, and the Tapajos to the last rapid, the Maranhão Grande, is a continuous series of formidable cataracts and rapids; but from the Maranhão Grande to its mouth, about 188 miles, the river can be navigated by large vessels. For its last 100 miles, it is from 4 to 9 miles wide, and much of it very deep. The valley of the Tapajos is bordered on both sides by bluffs. They are from 300 to 400 feet high along the lower river; but, a few miles above Santarem, they retire from the eastern side and only approach the Amazon flood-plain some miles below Santarem.

The MADEIRA has its junction with the Amazon 870 miles by river above Pará, and almost rivals it in the volume of its waters. It rises over 50 feet during the rainy season, and the largest ocean steamers may ascend it to the Fall of San Antonio, 663 miles above its mouth; but in the dry months, from June to November, it is only navigable, for the same distance, for craft drawing from 5 to 6 feet of water. According to the treaty of San Ildefonso, the Madeira commences at the confluence of the Guaporé with the Mamoré. Both of these streams have their headwaters almost in contact with those of the river Paraguay. The idea of a connecting canal is based on ignorance of local conditions. San Antonio is the first of a formidable series of cataracts and rapids, nineteen in number, which, for a river distance of 263 miles, obstruct the upper course of the Madeira until the last rapid, called Guajará Merim (or Small Pebble), is reached, a little below the union of the Guaporé with the Mamoré. The junction of the great river Beni with the Madeira is at the "Madeira" Fall, a vast and grand display of reefs, whirlpools, and boiling torrents. Between Guajará-Merim and this fall, inclusive, the Madeira receives the drainage of the north-eastern slopes of the Andes, from Santa Cruz de la Sierra to Cuzco, the whole of the south-western slope of Brazilian Matto-grosso, and the northern one of the Chiquitos sierras, an area about equal to that of France and Spain. The waters find their way to the falls of the Madeira by many great rivers, the principal of which, if we enumerate them from east to west, are the Guaporé or Itenez, the Baures or Blanco, the Itonama or San Miguel, the Mamoré, Beni and Mayutata, or Madre de Dios, all of which are reinforced by numerous secondary, but powerful affluents. The Guaporé presents many difficulties to continuous navigation; the Baures and Itonama offer hundreds of miles of navigable waters through beautiful plains; the Mamoré has been sounded by the writer, in the driest month of the year, for a distance of 500 miles above Guajará-Merim, and found never less than from 10 to 30 feet of water, with a current of from 1 to 3 miles an hour. Its Rio Grande branch, explored under the writer's instructions, was found navigable for craft drawing 3 feet of water to within 30 miles

of Santa Cruz de la Sierra—a level sandy plain intervening. The Grande is a river of enormous length, rising in a great valley of the Andes between the important cities of Sucre and Cochabamba, and having its upper waters in close touch with those of the Pilcomayo branch of the great river Paraguay. It makes a long curve through the mountains, and, after a course of about 800 miles, joins the Mamoré near 15° S. lat. The Chaparé, Securé, and Chimoré, tributaries of the Mamoré, are navigable for launches up to the base of the mountains, to within 130 miles of Cochabamba. The Beni has a fall, 18 miles above its mouth, called "La Esperanza"; beyond this, it is navigable for 217 miles to the port of Reyes for launches in the dry season, and larger craft in the wet one. The extreme source of the Beni is the little river La Paz, which rises in the inter-Andean region, a few miles south-east of Lake Titicaca, and flows as a rivulet through the Bolivian city of La Paz. From this point to Reyes, the river is a torrent. The principal affluent of the Beni, and one which exceeds it in volume, enters it 120 miles above its mouth, and is known to the Indians along its banks as the Mayu-tata. Its ramifications drain the slopes of the Andes between 12° and 15° of latitude. It was long thought to be a tributary of the Purús, until the ill-fated Maldonado demonstrated that it belonged to the Madeira river system. It is navigable, in the wet season, to the base of the Andes, to within 180 miles of Cuzco. Its upper waters are separated by only a short transitable portage from those of the Ucayali. When, however, the river is low, it is obstructed by several shoals, and violent, but surmountable currents, and its middle course has two rapids, each with the usual "head, body, and tail." It has sixty-three islands, great and small, from its mouth to its principal affluent, the Inambari, which joins it from the south, flowing along the base of the Andes. Its bed is definitively formed, its banks are solid, and the country it traverses is picturesque and frequently of exceeding beauty. All of the upper branches of the river Madeira find their way to the falls across the open, almost level Mojos and Beni plains, 35,000 square miles of which are yearly flooded to an average depth of about 3 feet, for a period of from three to four months. They rival if they do not exceed in fertility the valley of the Nile, and are the healthiest and most inviting agricultural and grazing region of the basin of the Amazon.

The PURÚS, a very sluggish river, enters the Amazon west of the Madeira, which it parallels as far south as the falls of the latter stream. It runs through a continuous forest at the bottom of the great depression lying between the Madeira river, which skirts the edge of the Brazilian sandstone plateau, and the Ucayali, which hugs the base of the Andes. Chandless found its elevation above sea level to be only 107 feet 590 miles from its mouth. It is one of the most crooked streams in the world, and its length, in a straight line, is less than half that by its curves. It is practically only a drainage ditch for the half-submerged, lake-flooded district it traverses. Its width is very uniform for 1000 miles up, and, for 800 miles, its depth is never less than 45 feet. It is navigable by steamers for 1648 miles as far as the little stream, the Curumahá, but only by light-draft craft. Chandless ascended it 1866 miles. At 1792 miles, it forks into two small streams. Occasionally a cliff touches the river, but in general the lands are subject to yearly inundations throughout its course, the river rising at times above 50 feet, the numerous lakes to the right and left serving as reservoirs. Its main tributary, the Aquiry or Acre, enters from the right about 1104 miles from the Amazon. Its sources are near those of the Mayu-tata. It is navigable for a period of about five months of the year, when the Purús valley is inundated;

and, for the remaining seven months, only canoes can ascend it sufficiently high to communicate overland with the settlements in the great india-rubber districts of the Mayu-tata and lower Beni : thus these regions are forced to seek a canoe outlet for their rich products by the very dangerous, costly, and laborious route of the falls of the Madeira.

The JURUÁ is the next great southern affluent of the Amazon west of the Purús, sharing with this the bottom of the immense inland Amazon depression, and having all the characteristics of the Purús as regards curvature, sluggishness, and general features of the low, half-flooded forest country it traverses. It rises among the Ucayali highlands, and is navigable and unobstructed for a distance of 1133 miles above its junction with the Amazon.

The JAVARY, the boundary line between Brazil and Peru, is another Amazon tributary of importance. It is supposed to be navigable, by canoe, for 900 miles above its mouth to its sources among the Ucayali highlands, but only 260 have been found suitable for steam navigation. The Brazilian Boundary Commission ascended it, in 1866, to the junction of the Shino with its Jaquirana branch. The country it traverses in its extremely sinuous course is very level, similar in character to that of the Juruá, and is a forested wilderness occupied by a few savage hordes.

The UCAYALI, which rises only about 70 miles north of Lake Titicaca, is the most interesting branch of the Amazon next to the Madeira. Peru has fitted out many costly and ably-conducted expeditions to explore it. One of them (1867) claimed to have reached within 240 miles of Lima, and the little steamer *Napo* forced its way up the violent currents for 77 miles above the junction with the Pachitea river as far as the river Tambo, or Apurimac, 770 miles from the confluence of the Ucayali with the Amazon. The *Napo* then succeeded in ascending the Urubamba branch of the Ucayali 35 miles above its union with the Tambo, to a point 200 miles north of Cuzco. The remainder of the Urubamba, as shown by Bosquet in 1806, and Castelnau in 1846, is interrupted by cascades, reefs, and numberless other obstacles to navigation. The Tambo, which rises in the Vilcanota knot of mountains south of Cuzco, is a torrential stream valueless for commercial purposes. The banks of the Ucayali for 500 miles up are low, and, in the rainy season, extensively inundated.

The HUALLAGA, which joins the Amazon to the west of the Ucayali, rises high among the mountains, in about 10° 30' S. lat., on the slopes of the celebrated Cerro de Pasco. For nearly its entire length, it is an impetuous torrent running through a succession of gorges. It has forty-two rapids, its last obstruction being the Pongo de Aguirre, so called from the traitor Aguirre, who passed there. To this point, 140 miles from the Amazon, the Huallaga can be ascended by large river steamers. Between the Huallaga and the Ucayali lies the famous "Pampa del Sacramento," a level region of stoneless alluvial lands covered with thick, dark forests, first entered by the missionaries in 1726. It is about 300 miles long, from north to south, and varies in width from 40 to 100 miles. Many streams, navigable for canoes, penetrate this region from the Ucayali and the Huallaga. It is still occupied by savage tribes.

The river MARAÑON rises about 100 miles to the north-east of Lima. It flows through a deeply-eroded Andean valley, in a north-west direction, along the eastern base of the Cordillera of the Andes, as far as 5° 36' S. lat.; then it makes a great bend to the north-east, and with irresistible power cuts through the inland Andes, until, at the Pongo de Manseriche, it victoriously breaks away from the

mountains to flow onwards through the plains under the name of the Amazon. Barred by reefs, and full of rapids and impetuous currents, it cannot become a commercial avenue. At the point where it makes its great bend, the river Chinchipe pours into it from southern Ecuador. Just below this, the mountains close in on either side of the Marañon, forming narrows or *pongos*, for a length of 35 miles, where, besides numerous whirlpools, there are no less than thirty-five formidable rapids, the series concluding with three cataracts just before reaching the river Imasa, or Chunchunga, near the mouth of which La Condamine embarked, in the 18th century, to descend the Amazon. Here, the general level of the country begins to decrease in elevation, with only a few mountain spurs, which, from time to time, push as far as the river and form *pongos* of minor importance, and less dangerous to descend. Finally, after passing the narrows of Guaracayo, the *cerros* gradually disappear, and, for a distance of about 20 miles, the river is full of islands, and there is nothing visible from its low banks but an immense forest-covered plain. But the last barrier has yet to be passed, the Pongo de Manseriche, 3 miles long, just below the mouth of the Rio Santiago, and between it and the old abandoned missionary station of Borja, in 38° 30' S. lat. and 77° 30' 40" W. long. According to Captain Carbajal, who descended it in the little steamer *Napo* in 1868, it is a vast rent in the Andes about 2000 feet deep, narrowing in places to a width of only 100 feet, the precipices "seeming to close in at the top." Through this dark cañon, the Marañon leaps along, at times, at the rate of 12 miles an hour.¹ From the northern slope of its basin, the Amazon receives many tributaries, but their combined volume of water is not nearly so great as that contributed to the parent stream by its affluents from the south. That part of Brazil lying between the Amazon and French, Dutch, and British Guiana, and bounded on the west by the Rio Negro, is known as Brazilian Guiana. It is the southern watershed of a tortuous, low chain of mountains running, roughly, east and west. Their northern slope, which is occupied by the three Guianas first named, is saturated and river-torn; but their southern one, Brazilian Guiana, is in general thirsty and semi-barren, and the driest region of the Amazon valley. It is an area which has been left almost in the undisturbed possession of nomadic Indian tribes, whose scanty numbers find it difficult to solve the food problem. From the *divortium aquarum* between French Guiana and Brazil, known as the Tumuc-humac range of highlands, two minor streams, the Yary and the Paron, reach the Amazon across the intervening broken and barren tableland. They are full of rapids and reefs.

The TROMBETAS is the first river of importance we meet on the northern side as we ascend the Amazon. Its confluence with this is just above the town of Obidos. It has its sources in the Guiana highlands, but its long course is frequently interrupted by violent currents, rocky barriers, and rapids. The inferior zone of the river, as far up as the first fall, the Porteira, has but little broken water and is low and swampy; but above the long series of cataracts and rapids the character and aspect of the valley completely change, and the climate is much better. The river is navigable for 135 miles above its mouth.

The NEGRO, the great northern tributary of the Amazon, has its sources along the watershed between the Orinoco and the Amazon basins, and also connects with the Orinoco at one point. Its main affluent is the Uaupes, which disputes with the headwaters of the Guaviari

¹ One of the most daring deeds of exploration ever known in South America was done by the engineer A. Wertheman. He fitted out three rafts, in August 1870, and descended this whole series of rapids and cascades from the Rio Chinchipe to Borja.

branch of the Orinoco the drainage of the eastern slope of the "oriental" Andes of Colombia. The Negro is navigable for 450 miles above its mouth for 4 feet of water in the dry season, but it has many sandbanks and minor difficulties. In the wet season, it overflows the country far and wide, sometimes to a breadth of 20 miles, for long distances, and for 400 miles up, as far as Santa Isabella, is a succession of lagoons, full of long islands and intricate channels, and the slope of the country is so gentle that the river has almost no current. But just before reaching the Uaupes there is a long series of reefs, over which the river violently flows in cataracts, rapids, and whirlpools. The Uaupes is full of similar obstacles, some fifty rapids barring its navigation, although a long stretch of its upper course is said to be free from them, and to flow gently through a forested country. Despite the impediments, canoes ascend this stream to the Andes.

The *Branco* is the principal affluent of the Negro from the north; it is enriched by many streams from the sierras which separate Venezuela and British Guiana from Brazil. Its two upper main tributaries are the Uraricuera and the Taqutá. The latter almost links its sources with those of the Essequibo. The Branco flows nearly south, and finds its way into the Negro through several channels and a chain of lagoons similar to those of the latter river. It is 350 miles long, up to its Uraricuera confluence. It has numerous islands, and, 235 miles above its mouth, it is broken by a bad series of rapids.

The *YAPURÁ*. West of the Negro the Amazon receives three more imposing streams from the north-west—the Yapurá, the Iça or Putumayo, and the Napo. The first was formerly known as the Hyapora, but its Brazilian part is now called the Yapurá and its Colombian portion the Caquetá. Barão de Marajo gives it 600 miles of navigable stretches; but Crevaux, who descended it, describes it as a frightful river—forests, jungles, rapids, cataracts, torrential rains, cannibals, and fevers throughout its course. It rises in the Colombian Andes, nearly in touch with the sources of the Magdalena, and augments its volume from many branches as it courses through Colombia. It was long supposed to have eight mouths; but Ribeiro de Sampaio, in his voyage of 1774, determined that there was but one real mouth, and that the supposed others are all *furos* or caños. In 1864-68, the Brazilian Government made a somewhat careful examination of the Brazilian part of the river, as far up as the rapid of Cupaty. Several very easy and almost complete water-routes exist between the Yapurá and Negro across the low, flat intervening country. Barão de Marajo says there are six of them, and one which connects the upper Yapurá with the Uaupes branch of the Negro; thus the Indian tribes of the respective valleys have facile contact with each other.

The *IÇA*, or *PUTUMAYO*, west of and parallel to the Yapurá, was found more agreeable to navigate by Crevaux. He ascended it in a steamer drawing 6 feet of water, and running day and night. He reached Cuemby, 800 miles above its mouth, without finding a single rapid. Cuemby is only 200 miles from the Pacific Ocean, in a straight line passing through the town of Pasto in southern Colombia. There was not a stone to be seen up to the base of the Andes; the river banks were of argillaceous earth and the bottom of fine sand.

The *NAPO* rises on the flanks of the volcanoes of Antisana, Sincholagua, and Cotopaxi. Before it reaches the plains, it receives a great number of small streams from impenetrable, saturated, and much broken mountainous districts, where the dense and varied vegetation seems to fight for every square foot of ground. From the north, it is joined by the river Coca, having its sources in the gorges of Cayambé on the equator, and also a powerful river, the *Aguariço*, having its headwaters between

Cayambé and the Colombian frontier. From the west, it receives a secondary tributary, the Curaray, from the Andean slopes, between Cotopaxi and the volcano of Tunguragua. From its Coca branch to the mouth of the Curaray, the Napo is full of snags and shelving sandbanks, and throws out numerous caños among jungle-tangled islands, which in the wet season are flooded, giving the river an immense width. From the Coca to the Amazon, it runs through a forested plain where not a hill is visible from the river—its uniformly level banks being only interrupted by swamps and lagoons. From the Amazon, the Napo is navigable for river craft up to its Curaray branch, a distance of about 216 miles, and perhaps a few miles farther; thence, by painful canoe navigation, its upper waters may be ascended as far as Santa Rosa, the usual point of embarkation for any venturesome traveller who descends from the Quito tableland. The Coca river may be penetrated as far up as its middle course, where it is jammed between two mountain walls, in a deep cañon, along which it dashes over high falls and numerous reefs. This is the stream made famous by the expedition of Gonzalo Pizarro.

The *NANAY* is the next Amazon tributary of importance west of the Napo. It belongs entirely to the lowlands, and is very crooked, has a slow current, and divides much into caños and strings of lagoons which flood the flat, low areas of country on either side. It is simply the drainage ditch of districts which are extensively overflowed in the rainy season. Captain Butt ascended it 195 miles, to near its source.

The *TIGRE* is the next west of the Nanay, and is navigable for 125 miles from its confluence with the Amazon. Like the Nanay, it belongs wholly to the plains. Its mouth is 42 miles west of the junction of the Ucayali with the Amazon. Continuing west from the Tigre we have the Parinari, Chambira, and Nucuray, all short lowland streams, resembling the Nanay in character.

The *PASTAZA* is the next large river we meet. It rises on the Ecuadorian tableland, where a branch from the valley of Riobamba unites with one from the Latacunga basin and breaks through the inland range of the Andes; and joined, afterwards, by several important tributaries, finds its way south-east among the gorges; thence it turns southward into the plains, and enters the Amazon at a point about 60 miles west of the mouth of the Huallaga. So far as known, it is a stream of no value except for canoe navigation. Its rise and fall are rapid and uncertain, and it is shallow and full of sandbanks and snags.

The *MORONA* flows parallel to the Pastaza and immediately to the west of it, and is the last stream of any importance on the northern side of the Amazon before reaching the Pongo de Manseriche. It is formed from a multitude of water-courses which descend the slopes of the Ecuadorian Andes south of the gigantic volcano of Sangai; but it soon reaches the plain, which commences where it receives its Cusulima branch. The Morona is navigable for small craft for about 300 miles above its mouth, but it is extremely tortuous. Canoes may ascend many of its branches, especially the Cusulima and the Miazal, the latter almost to the base of Sangai. The Morona has been the scene of many rude explorations, with the hope of finding it serviceable as a commercial route between the inter-Andean tableland of Ecuador and the Amazon river. A river called the Pante dashes through the eastern Andes from the valley of Cuenca; and a second, the Zamora, has broken through the same range from the basin of Loja. Swollen by their many affluents, they reach the lowlands and unite their waters to form the Santiago, which flows into the Marañon at the head of the Pongo de Manseriche. There is but little known of a trustworthy character re-

garding this river, but Wolf says that it is probably navigable up to the junction of the Paute with the Zamora.

The Main River.

The AMAZON MAIN RIVER is navigable for ocean steamers as far as Iquitos, 2300 miles from the sea, and 486 miles higher up for vessels drawing 14 feet of water, as far as Achnal Point. Beyond that, according to Tucker, confirmed by Wertheman, it is unsafe; but small steamers frequently ascend to the Pongo de Manseriche, just above Achnal Point. The average current of the Amazon is about 3 miles an hour; but, especially in flood, it dashes through some of its contracted channels at the rate of 5 miles. The U.S. steamer *Wilmington* ascended it to Iquitos in 1899. Commander Todd reports that the average depth of the river in the height of the rainy season is 120 feet. It commences to rise in November, and increases in volume until June, and then falls until the end of October. The rise of the Negro branch is not synchronous; for the steady rains do not commence in its valley until February or March. By June it is full, and then it begins to fall with the Amazon. According to Bates, the Madeira "rises and sinks" two months earlier than the Amazon. The Amazon at times broadens to 4 and 6 miles. Occasionally, for long distances, it divides into two main streams with inland, lateral channels, all connected by a complicated system of natural canals, cutting the low, flat *igapo* lands, which are never more than 15 feet above low river, into almost numberless islands. At the narrows of Obidos, 400 miles from the sea, it is compressed into a single bed a mile wide and over 200 feet deep, through which the water rushes at the rate of 4 to 5 miles an hour. In the rainy season it inundates the country throughout its course to the extent of several hundred thousand square miles, covering the flood-plain, called *vargem*. The flood-levels are in places from 40 to 50 feet high above low river. Taking four, roughly equidistant places, the rise at Iquitos is 20 feet, at Tefé 45, near Obidos 35, and at Pará 12 feet.

The first high land met in ascending the river is on the north bank, opposite the mouth of the Xingú, and extends for about 150 miles up, as far as Monte Alegre. It is a series of steep, table-topped hills, cut down to a kind of terrace which lies between them and the river. Monte Alegre reaches an altitude of several hundred feet. On the south side, above the Xingú, a line of low bluffs extends, in a series of gentle curves with hardly any breaks nearly to Santarem, but a considerable distance inland, bordering the flood plain, which is many miles wide. Then they bend to the south-west, and, abutting upon the lower Tapajos, merge into the bluffs which form the terrace margin of that river valley. The next high land on the north side is Obidos, a bluff, 56 feet above the river, backed by low hills. From Serpa, nearly opposite the river Madeira, to near the mouth of the Rio Negro, the banks are low, until approaching Manãos, they are rolling hills; but from the Negro, for 600 miles, as far up as the village of Canaria, at the great bend of the Amazon, only very low land is found, resembling that at the mouth of the river. Vast areas of it are submerged at high water, above which only the upper part of the trees of the sombre forests appear. At Canaria, the high land commences and continues as far as Tabatinga, and thence up stream.

On the south side, from the Tapajos to the river Madeira, the banks are usually low, although two or three hills break the general monotony. From the latter river, however, to the Ucayali, a distance of nearly 1500 miles, the forested banks are just out of water, and are inundated

long before the river attains its maximum flood-line. Thence to the Huallaga the elevation of the land is somewhat greater; but not until this river is passed, and the Pongo de Manseriche approached, does the swelling ground of the Andean foot-hills raise the country above flood-level.

The Amazon is not a continuous incline, but probably consists of long, level stretches connected by short inclined planes of extremely little fall, sufficient, however, owing to its great depth, to give the gigantic volume of water a continuous impulse towards the ocean. The lower Amazon presents every evidence of having once been an ocean bay, the upper waters of which washed the cliffs near Obidos. Only about 10 per cent. of the water discharged by the mighty stream enters it below Obidos, very little of which is from the northern slope of the valley. The drainage area of the Amazon basin above Obidos is about 1,945,000 square miles, and, below, only about 423,000 square miles, or say 20 per cent., exclusive of the 354,000 square miles of the Tocantins basin.

The width of the mouth of the monarch river is usually measured from Cabo do Norte to Punto Patijoca, a distance of 207 statute miles; but this includes the ocean outlet, 40 miles wide, of the Pará river, which should be deducted, as this stream is only the lower reach of the Tocantins.

Following the coast, a little to the north of Cabo do Norte, and for 100 miles along its Guiana margin up the Amazon, is a belt of half-submerged islands and shallow sandbanks. Here the tidal phenomenon called the *bore*, or Pororoca, occurs, where the soundings are not over 4 fathoms. It commences with a roar, constantly increasing, and advances at the rate of from 10 to 15 miles an hour, with a breaking wall of water from 5 to 12 feet high. Under such conditions of warfare between the ocean and the river, it is not surprising that the former is rapidly eating away the coast and that the vast volume of silt carried by the Amazon finds it impossible to build up a delta.

The Amazon is not so much a river as it is a gigantic reservoir, extending from the sea to the base of the Andes, and, in the wet season, varying in width from 5 to 400 miles. Special attention has already been called to the fourteen great streams which discharge into this reservoir, but it receives a multitude of secondary rivers, which in any other part of the world would also be termed great.

For 350 years after the discovery of the Amazon, by Pinzon, in 1500, the Portuguese portion of its basin remained almost an undisturbed wilderness, occupied by Indian tribes whom the food quest had split into countless fragments. It is doubtful if its indigenous inhabitants ever exceeded one to every 5 square miles of territory, this being the maximum it could support under the existing conditions of the period in question, and taking into account Indian methods of life. A few settlements on the banks of the main river and some of its tributaries, either for trade with the Indians or for evangelizing purposes, had been founded by the Portuguese pioneers of European civilization. The total population of the Brazilian portion of the Amazon basin in 1850 was perhaps 300,000, of whom about two-thirds were white and slaves, the latter numbering about 25,000. The principal commercial city, Pará, had from 10,000 to 12,000 inhabitants, including slaves. The town of Manãos, at the mouth of the Rio Negro, had from 1000 to 1500 population; but all the remaining villages, as far up as Tabatinga, on the Brazilian frontier of Peru, were wretched little groups of houses which appeared to have timidly effected a lodgment on the river bank, as if they feared to challenge the mysteries of

Physical
character-
istics.

Popula-
tion, trade,
&c.

the sombre and gigantic forests behind them. The value of the export and import trade of the whole valley in 1850 was but £500,000.

On the 6th September 1850, the great emperor, Dom Pedro II., sanctioned a law authorizing steam navigation on the Amazon, and confided to an illustrious Brazilian, Barão Mauá (Irineu Evangelista de Sousa), the task of carrying it into effect. He organized the "Compania de Navegação e Commercio do Amazonas" at Rio de Janeiro in 1852; and in the following year it commenced operations with three small steamers, the *Monarch*, the *Marajo*, and *Rio Negro*. At first, the navigation was principally confined to the main river; and even in 1857 a modification of the Government contract only obliged the company to a monthly service between Pará and Manãos, with steamers of 200 tons cargo capacity, a second line to make six round voyages a year between Manãos and Tabatinga, and a third, two trips a month between Pará and Cameté. The Government paid the company a subvention of £3935 monthly. Thus the first impulse of modern progress was given to the dormant valley. The success of the venture called attention to the unoccupied field; a second company soon opened commerce on the Madeira, Purús, and Negro; a third established a line between Pará and Manãos; and a fourth found it profitable to navigate some of the smaller streams; while, in the interval, the Amazonas Company had largely increased its fine fleet. Meanwhile private individuals were building and running small steam craft of their own, not only upon the main river but upon many of its affluents. The Government of Brazil, constantly pressed by the maritime powers and by the countries encircling the upper Amazon basin, decreed, on the 31st July 1867, the opening of the Amazon to all flags; but limited this to certain defined points — Tabatinga, on the Amazon; Cameté, on the Tocantins; Santarem, on the Tapajos; Borba, on the Madeira; Manãos, on the Rio Negro; the decree to take effect on 7th September of the same year. Pará is now a city of over 100,000 inhabitants, Manãos has about 40,000, and the Peruvian town of Iquitos, 10,000. In 1898 there entered the port of Pará 503 ocean steamers and 123 sailing ships—a total of 610,597 tons; and in 1899 the entries of English ocean-going ships reached 314,646 tons register. The first direct foreign trade with Manãos was commenced about 1874. There is now a regular service of two English, one Italian, and one Portuguese line—a total of 35 steamships, representing 52,953 tons register. There is also a Brazilian line of seven ships, of 1999 tons each, running between Manãos and Rio de Janeiro.

The local trade of the river is carried on by the English successors to the Amazonas Company—the Amazon Steam Navigation Company—with 29 steamers, aggregating 9184 registered tons. In addition to its excellent fleet, there are 150 small river steamers belonging to companies and firms in the rubber trade, and 12 of from 150 to 300 tons each, navigating the Negro, Madeira, and Purús rivers. The principal exports of the valley are india-rubber, cacao, Brazil nuts, and a few other products of very minor importance. The india-rubber yield is now from 25,000 to 26,000 tons yearly. The finest quality comes from the Acre and Beni districts of Bolivia, especially from the valley of the Acre (or Aquiry) branch of the river Purús. The yield of these for 1898 was 3151 tons, of which 2000 tons was the official estimate of the product of the Acre district; for 1899, it was 1150 tons; and for the first eleven months of 1900 it was only 791 tons, the decrease being due to the recent unsuccessful attempt of the rubber collectors to segregate the region of the Acre from Bolivia and form a separate republic. Of the rubber production of the Amazon basin, the State of

Pará gives about 40 per cent. The cocoa tree is not cultivated, but grows wild in great abundance. The quantity exported for 1899 was 4054 tons. There is but one railway in the whole valley. It runs from Pará towards the coast and is 65 miles long. The cities of Pará and Manãos have excellent tramways, many fine public buildings and private residences, gardens and public squares, all of which give evidence of artistic taste and great prosperity. The import dues collected at the port of Pará in 1899 by the national Government amounted to £844,000. The revenues of the State of Amazonas for the same year were nearly £750,000, of which £476,000 were derived from export duties.

The number of inhabitants in the Brazilian Amazon basin (the States of Amazonas and Pará) is purely a matter of rough estimate. There may be 500,000 or 600,000, or more; for the immigration, during recent years, from the other parts of Brazil has been large, due to the rubber excitement. The influx from the State of Ceará aloné, from 1892 to 1899 inclusive, reached 98,348.

As Commander Todd, in his report to the United States Government, says: "The crying need of the Amazon valley is food for the people. . . . At the small towns along the river it is nearly impossible to obtain beef, vegetables, or fruit of any sort, and the inhabitants depend largely upon river fish, mandioc, and canned goods for their subsistence. . . . The ship's company lived, the greater part of the time, upon the regular sea ration, and any ship ascending the Amazon should be well supplied with its own provisions, as it is impossible to live upon the country." Although 400 years have passed since the discovery of the Amazon river, there are probably not 20 square miles of its basin under cultivation, excluding the limited and rudely cultivated areas among the mountains at its extreme headwaters, which are inaccessible to commerce. The extensive exports of the mighty valley are entirely derived from the products of the forest.

(G. E. C.)

Amazonas, the largest state of Brazil, in the extreme west of the Republic, has an area of 732,250 square miles. The population in 1872 was 56,610, and in 1890 147,915, of whom nearly two-thirds were Indians. The capital, Manãos, at the mouth of the Rio Negro, has a population of 30,000. The chief towns are Teffe, Ita-coatiara (or Serpa), Parintins, Codajaz, and San Gabriel. (See also under AMAZON.)

Amazonas, an interior department of northern Peru, with an area of 13,943 square miles and a population officially estimated at 70,676 in 1896. It is subdivided into three provinces, Bongara, Luya, and Chachapoyas; the principal town, Chachapoyas, has a population of 6000.

Ambala. See UMBALLA.

Amba Mariam. See ABYSSINIA.

Amberg, a town of Bavaria, Germany, district Upper Palatinate, 42 miles E. from Nuremberg by rail. The manufacture of stoneware, zinc goods, and colours is carried on. A former Jesuit monastery is now used for a grammar school and seminary. There are a pilgrimage church, on a hill 1621 ft. high, a large convict prison for men, an industrial and commercial school, &c. Population, 15,812 (1885); 20,200 (1895).

Ambleside, a market-town in the Appleby parliamentary division of Westmorland, England, a mile from the north end of Windermere. Recent erections are a preparatory school for the novitiate of St Norbert's Home and assembly rooms. Bobbins are manufactured, and in the neighbourhood are slate quarries. Area of parish (an urban district), 4421 acres. Population in 1881, 1989; in 1891, 2360; in 1901, 2536.

Amboyna, a Dutch colony and residency in the east of the East Indian archipelago, which shares with the residency of Ternate the administration of the Moluccas, the previous Government of which was abolished in 1867. The residency includes a mass of islands in the Banda Sea (2° 30'–8° 20' S. and 125° 45'–135° E.) and is now divided for administrative purposes into nine districts (*afdeelingen*): 1, Amboyna, the island of that name; 2, Saparua, with Oma and Nusa Laut; 3, Kajeli (Eastern Buru); 4, Masareti (Western Buru); 5, Kairatu (Western Ceram); 6, Wahai (the northern part of Mid-Ceram); 7, Amahai (the southern part of Mid-Ceram); 8, the Banda Isles, with East Ceram, Ceram Laut, and Goram; 9, The islands of Aru, Ké, Timor Laut or Tinimber, and the south-western islands. Since 1874 several residents (Riedel, van Hoëvell, &c., see below) have contributed to the geography and ethnography of various groups. The population of the residency (area, about 19,840 square miles) was estimated in 1898 at 295,768 (natives 291,763, Europeans 2346, Chinese 913, Arabs 722, other foreigners 24). The products and means of subsistence in the different groups of islands vary, the culture of cloves being mainly confined to Banda and Amboyna; shipbuilding and the timber trade to the Ké islands; the extraction of cajuput oil to Buru. The shipping, fisheries, and trade are unimportant and generally declining.

See van HOËVELL, *Ambon en de Eliaser* (Dordrecht, 1875).—RIEDEL, *De sluik-en kroesharige rassen tusschen Selebes en Papua* (den Haag, 1886).—MARTIN, *Reisen in den Molukken* (Leiden, 1894).

Amboyna (Dutch *Ambon*), the chief island and town of the above residency. The former, lying between 3° 28'–3° 48' S. and 127° 58'–128° 26' E., is the last of a series of volcanic isles which form an inner circle in the archipelago round the Banda Sea (Martin). The highest mountains, Wawani (3609 feet) and Salhutu (4020 feet), have hot springs and solfataras. They are considered to be volcanoes, and the mountains of the neighbouring Uliasser islands the remains of volcanoes. Granite and serpentine rocks predominate; but the shores of Amboyna bay are of chalk, and contain stalactite caves (the chief, Batu Lobang). The surface is fertile, the rivers are small and not navigable, and the roads are mere footpaths. Cocoa is one of the products. The population (estimated at 30,000) is divided into two classes—*orang borger* or citizens, and *orang negri* or villagers, the former being a class of native origin enjoying certain privileges conferred on their ancestors by the old Dutch East India Company. The chief town and seat of the resident and military commander of the Moluccas is protected by Fort Victoria, a clean little town with wide streets and numerous schools and churches. Agriculture, fisheries, and trade furnish the chief means of subsistence. The combined value of the exports and imports of late years has been about £85,000 (£83,333 literal conversion). The population is about 8000 (788 Europeans, 696 Chinese, 351 Arabs, 6218 natives).

Ambriz. See ANGOLA.

Ambrosiaster.—A commentary on St Paul's Epistles, "brief in words but weighty in matter," and valuable for the criticism of the Latin text of the New Testament was formerly but erroneously attributed to St Ambrose; and its author is usually spoken of as Ambrosiaster or pseudo-Ambrose. In modern days it has been ascribed to almost every known Hilary (owing to the fact that St Augustine cites it as by "Sanctus Hilarius"), and to many other writers; above all to Hilary the Roman deacon and (by Langen) to the presbyter Faustinus.

Dom Morin has lately argued, with very great plausibility, that the author was one Isaac the Jew, who became a Christian and joined the party of the anti-pope Ursinus, and was instigated by them to make criminal charges against Pope Damasus. These were ultimately dismissed, and Isaac was exiled to Spain 378-380. In 380 he relapsed to Judaism; and nothing appears to be known of his later life.

Dom Morin first shows that none of the earlier attempts to identify Ambrosiaster can be accepted as satisfactory; that the *Quaestiones Veteris et Novi Testamenti* formerly ascribed to Augustine are also his (the attempt of C. Marold to disprove this breaking down entirely); that he wrote between 374 and 384 A.D., and that he lived and wrote at Rome. Then he compares the *Quaestiones* and *Commentaria* with the little tract of Isaac the Jew on the Trinity and Incarnation, and with an incomplete *Expositio Fidei* printed by Caspari (*Kirchenhist. Anecdota*, 304 f), which, if not part of the same work, is nearly allied to it; and the comparison shows how close their literary and theological affinities are. Next, Ambrosiaster's writings are shown to contain just such characteristics as might be expected from Isaac the Jew: a capacious spirit of reform, exact knowledge of Judaism, and a legalist temperament; whilst there is no insuperable objection to such authorship. And lastly, the later history of Isaac would account for the subsequent uncertainty as to the authorship of the writings.

See G. MORIN. "L'Ambrosiaster et le juif converti Isaac" in *Revue d'histoire et de littérature religieuses*, tom. iv. 97 f. Paris, 1899.—ARNOLD. Art. "Ambrosiaster" in Herzog-Hauck, *Real-Encyclopädie für protestantische Theologie*, i. 441. Leipzig, 1896.—J. LANGEN. *Geschichte der römischen Kirche*, i. 600 f. Bonn, 1881. (W. E. Co.)

Ambulance.—Medical organization for military field service comprises all the arrangements for the care and treatment of the sick and wounded from the time they are injured or taken ill till they are able to return to duty or are invalided home. In the British service, not only land transport but hospital ships are required. The working of the system is as follows (the case of a soldier wounded in action in South Africa being taken as an example). When he falls he is attended by the regimental surgeon and stretcher-bearers, who apply some extemporized method of stopping bleeding and dress the wound with the dressing—a packet of antiseptic appliances—which every fighting man carries stitched into the inside of his tunic, and which contains all things necessary for dressing and bandaging an ordinary gunshot wound. From the field he is carried on a stretcher by the men of the bearer company of the Royal Army Medical Corps to the collecting station, where he is placed in an ambulance waggon of the first line of assistance and taken to the dressing station. Here his wound will be examined, any operation urgently required will be performed, and a specification tally stating the nature of the injury and any other important facts connected with the case will be attached to him (if this has not already been done by the regimental surgeon), in order to avoid the disturbance and pain of repeated examinations. After this, and perhaps the administration of nourishments, stimulants, or opiates, the patient is moved to the field hospital in an ambulance waggon of the second line of assistance. From the field hospital he is transferred as soon as possible by the ambulance train to a general hospital at the advanced base of operations, and from there in due time in another train to the base of operations at the coast, from which he is ultimately either returned to duty or sent home in a hospital ship.

The organization by which these requirements are fulfilled is the following:—Every regiment and fighting unit has posted to it, on proceeding on active service, a medical officer who looks after the health of the men and advises the commanding officer on sanitary matters. When the regiment goes into action he takes command of the regi-

mental stretcher-bearers to the number of two per company who have previously been instructed in first aid and in the carrying of the wounded on stretchers. These men leave their arms behind and wear the Red Cross armlets so as to be under the protection of the Geneva Convention, but when a battle takes the form of magazine

and sedatives, and then carry them back on stretchers to the collecting station in the rear, whence they are conveyed to the dressing station in waggons or other form of transport (mule cacolets or litters in mountainous districts where wheeled carriages cannot go, camel cacolets and litters in the Sudan, dhoolies or Lushai dandies in India, hammocks on the West-Coast of Africa, or sedan chairs in China). Cacolets are seats slung on each side of a pack saddle. British ambulance waggons (Figs. 1, 3), which are built very strongly to stand rough roads, are of several patterns. They have been reported upon as heavy and uncomfortable in the South African war, and they can only carry two men so seriously wounded as to have to lie down, besides those seated; but a new vehicle has been tried which will convey four cases lying down as well as six seated, or fourteen all seated. All patterns of waggons weigh from 17½ to 18½ cwt. At the dressing station—which ought to be out of range of the firing, and near a good water supply—the patient is made as comfortable as possible; nourishment and stimulants are administered, and he is then taken to the field hospital. There is one field hospital to each brigade, but since in larger organizations extra accommodation is required for the corps troops not included in brigades, such as the ammunition supply columns, balloon and bridging detachments, &c.,

FIG. 1.—Type of British Army Ambulance.

rifle fire, continued for many hours without either side advancing or retiring much, it may not be the fault of the enemy that the bearers and medical officers are sometimes shot in attending to the wounded.

The bearer company, into whose charge the wounded man next passes, is composed of three officers, thirteen non-commissioned officers, and forty-eight privates of the Royal Army Medical Corps, with a detachment of the Army Service Corps for transport duties. There is one such bearer company to every brigade, and six to an army corps, and their duties are to collect and succour the wounded on the battlefield, handing them over to the field hospitals, with which the companies are closely associated, though separately organized. In the Indian

the total number of field hospitals for an army corps (roughly speaking 40,000 men) is ten. In times of great stress when it is desirable to remove the wounded quickly from the field, and there are no roads, or wheeled transport is not obtainable, it is becoming the custom to employ bearers in large numbers, temporarily engaged, whom a little training will render fairly efficient for the purpose. This was done in Natal at the battle of Spion Kop, and also in the Egyptian campaigns, where the local troops not required for the fighting line were requisitioned, and the arrangement was in both instances considered successful.

In India the rank and file of the Royal Army Medical Corps are not employed, the bearer work being carried out by natives called kahars, specially enlisted. These men are bearers by caste, and are most expert in carrying the dhoolies and dandies which are used instead of stretchers—except those used by the regimental (European) stretcher-bearers—and their courage on the battlefield is the admiration of all beholders. The same remark applies to the bheesties or water-carriers, who also accompany the troops into action. The ambulance organization of the army in India thus differs materially from that elsewhere. The main difference is that, as already stated, the rank and file of the Royal Army Medical Corps are not employed, although the commissioned officers are. The warrant and non-commissioned ranks are replaced by a most useful body of men of Anglo-Indian or Eurasian birth called the Subordinate Medical Department, the

FIG. 2.—Plan of Improved United States Army Ambulance.

army the bearer company is provided *pro tem.* from the personnel of the field hospital when there is a battle, and then reverts to the hospital again after it is over. The teaching of the South African war rather points to the advantage of the Indian plan, for after action the bearer company personnel should be available to give the much-needed help in the work of the field hospital. The bearers afford the wounded any treatment necessary, supply water

members of which, now called assistant surgeons, formerly apothecaries, receive a three years' training in medical work at the Indian universities, and are competent to perform the compounding of medicines and to undertake the management of all but the most serious cases of illness and injury. The privates of the Royal Army Medical

Army.*

Corps are replaced by natives graded as ward servants, cooks, water-carriers, and sweepers. The caste system necessitates this division of labour, and the men are not so efficient or so trustworthy as the regular soldiers whose places they take. The bearers of the sick and wounded are a separate and distinct class, as above explained, and they are in part attached to regiments as a portion of the regimental transport, and in part to the field hospital bearer companies on mobilization. The dandies, a more portable form of the old-fashioned dhoolie, are very comfortable, and have a canvas roof and curtain to keep off sun and rain. They are borne slung on a long bamboo upon the shoulders of four or more men, but being very heavy and clumsy are not well suited for mountain warfare; moreover, as they cannot be folded up into a smaller

compass for transport like a stretcher, they take up a great deal of room in railway trucks, and cannot be carried on the backs of animals. Hence riding ponies and mules are much used in Indian warfare for transporting the less severely wounded men. The ambulance tongas of India are small, very strongly built two-wheeled bullock or mule carriages capable of carrying four men seated or two lying down; but the most serious cases are carried in dandies all the way from the field to the hospital. In India it is necessary to provide separate hospitals for the white and black troops, and also to have accommodation in the latter case for the large numbers of non-combatant camp-followers who are employees of the commissariat department, servants, grooms, cooks, bullock- and mule-drivers, and the like. The frontier war of 1897-98 may be taken

Fig. 8.—Plan of British Army Ambulance.

to illustrate the medical organization of the Indian army. In that war 18,688 white troops, 41,677 native troops, and 32,696 followers were engaged, and for the accommodation of these there were fourteen field hospitals for white troops and twenty-two for native troops, each having 100 beds. Attached to the corps engaged were 150 dandies, 274 stretchers, and 900 bearers, while the field hospitals and bearer companies had a personnel of 9658, with 720 dandies and 720 tongas.

Field hospitals are each supposed to provide accommodation for 100 patients, who live upon their own field rations suitably cooked and supplemented by medical comforts. The patients are not supplied with hospital clothing, nor do they have beds, but lie on straw spread on the ground and covered with waterproof sheets and blankets. Thus field hospitals can and must at times accommodate more than the proper number of patients, but in the South African war their resources were at times con-

siderably overtaxed, with consequent discomfort and hardship. These hospitals are supposed to move with the army, and therefore it is imperative to pass the wounded quickly back from them to the hospitals on the lines of communication (which vary in number according to the length of that line), and thence to the general hospital at the base. The size of these hospitals on the lines of communication varies according to circumstances; they are as a rule dieted—that is to say, proper hospital diets and not field rations are issued to the patients, who also have beds and proper hospital clothing. In these hospitals there may be nursing sisters, who are unsuited for the rough life and work nearer the front. Sisters may also be employed on the hospital trains, which were found very useful in the South African war, being fitted with beds, kitchens, dispensaries, &c., so that the patients were removed long distances in comfort. Having arrived at the base of operations the wounded are transferred to the general hospitals. The numbers and

situation of these vary with circumstances and requirements, but according to regulations there is supposed to be one of 520 beds to each field force of 20,000 men. Each is fully equipped with beds, clothing, diets, &c., and the staff consists of 21 officers, 9 nursing sisters, 3 warrant officers, 25 non-commissioned officers, and about 120 privates. There are separate officers' wards. In South Africa, owing to the impossibility of the Royal Army Medical Corps meeting all the requirements of the enormous force engaged, many of the officers attached were civil doctors, and the rank and file were often civilians drawn from the St John's Ambulance Brigade and men

FIG. 4.—Type of English Civil Ambulance (side and rear view).

attached to each as administrator and organizer; and their personnel was made up of physicians, surgeons, nurses, dressers (who were medical students, and in some cases qualified surgeons), and servants. The numbers of course varied according to the size of the hospitals; in the case of the Portland hospital of 100 beds, for example, the staff comprised 41 individuals of the various grades.

Lastly, our wounded man is transferred to a hospital ship. This is fitted up with comfortable swinging cots in airy wards, refrigerators, punkahs for hot weather, and every other luxury which modern science can supply. Each division of an army corps is supposed to have attached to it, when necessary, a hospital ship of 200 or 250 beds, which is provided with medical officers, nursing

FIG. 5.—Type of American Civil Ambulance (side and rear view).

sisters, and the same staff and equipment as hospitals ashore.

temporarily enlisted from the Volunteer Medical Staff Corps. Many of the nursing sisters belonged to the Army Nursing Reserve, who are ordinarily employed in the civil hospitals, but liable to be drafted to the seat of war.

In the South African war the patriotism and liberality of the British public furnished several general hospitals, perfectly equipped and officered by some of the most eminent members of the medical profession in the United Kingdom. Among others may be mentioned the Princess Christian, the Imperial Yeomanry (both field and general), the Langman, the Portland, the Irish, Scottish, and Welsh hospitals. In addition to the staff of these hospitals, several eminent surgeons, including Sir Wm MacCormac and Sir Frederick (then Mr) Treves, went out as consultants. These civil hospitals were staffed entirely by civilians, except that an officer of the R.A.M.C. was

The medical staff of the regular army in the South African war in its later stage comprised the following officers:—1 surgeon-general, 11 colonels, 41 lieutenant-colonels, 183 majors, 71 captains, and 115 lieutenants—total 422 officers. The total strength of the Royal Army Medical Corps at that time was 905, and out of the balance there were 365 officers employed in other foreign stations, and only 118 at home. This shows how severely the war taxed the resources of the corps. Probably there were as many civil, colonial, and volunteer medical officers employed at the front as there were army medical officers. Of the rank and file of the Royal Army Medical Corps there were over 3000 men employed, and about the same number of St John's ambulance men, and other civilians and volunteers. To the army medical organization in war time is affiliated that of the Red Cross Society and other charitable associations, which during the South African war aided the medical services greatly by the provision of clothing, money, and numerous luxuries for the sick and wounded.

The material and equipment for the bearer companies, field hospitals, &c., are stored in times of peace at the various headquarters stations in the United Kingdom, and on the orders for

mobilization being issued, the personnel told off for each unit repairs to the allotted station, draws the equipment and transport, and embarks with the brigade to which it is attached. The transport of the ambulance department has profited by the concentration in strength of drugs, and the arrangements whereby space is economized. As the fighting man can carry in his wallet nourishment enough for thirty-six hours in the form of an emergency ration in a tin the size of a cigar-case, and enough sweetening material in the form of saccharine to last him a fortnight, in a bottle the size of a watch, so the medical department can take compressed tabloids of drugs, each tabloid being a dose, and each taking up about one-tenth of the space the drug would otherwise occupy; while the medical officers can carry hypodermic cases, not so large as ordinary cigarette-cases, containing a syringe and hundreds of doses of highly concentrated remedies. The traction-engines with the army can supply steam-power for X-ray and electric-light work, ice-making, &c.

The American Civil War (1861-65) marked the commencement of the modern ambulance system. The main feature, however, of the hospital organization throughout that campaign was the railway hospital service, which provided for the rapid conveyance of the sick and wounded to the rear of the contending armies. These hospital carriages (Fig. 2), equipped with medical stores and appliances for the transport of cases from the front to the base, were rapidly introduced into other armies, and played a great part in the ambulance service of the Franco-German war. On the continent of Europe, the two rival military Powers, France and Germany, who were not slow to follow the American lead, have since 1871 still further developed and improved their ambulance systems. The German hospital service for armies in the field was modified and extended by the "Kriegs Sanitäts ordnung" of 1878 and the "Kriegs Etappen ordnung" of 1887, which completed the organization by the addition in time of war of numerous subordinate offices and departments. The peace organization does not materially differ from the English system. The main divisions of the ambulance organization of the German army in the field would now fall into (1) sanitary detachments; (2) field hospitals; (3) flying hospitals; hospital reserve depôts; (5) commissions of transport ambulance; and (6) railway hospital trains. The whole administration of the ambulance service of the grand army in the field is in the hands of the chief of the army sanitary staff, who is attached to headquarters. Next in command come surgeons-general of armies operating in the field, surgeons-general of army corps, and under them again surgeons-in-chief of divisions and regiments. Civil consulting-surgeons of eminence, notably professors from the universities, are also attached to the various armies and divisions to co-operate with and act as advisers to the surgeons of the standing military surgical staff. The hospital transport service on the lines of communication is highly organized, and the hospital railway carriages are equipped on an elaborate scale. The French ambulance system, finally settled by the règlement of 1884, is organized on almost identical lines with the German. But the chief point wherein the German and French ambulance systems differ from the British lies in the military organization of the volunteer assistance offered by the various Red Cross societies under the Geneva flag. Whereas in France and Germany such aid is officially recognized and placed under direct military control, the English Red Cross societies act side by side with, but independently of, the military ambulance organization. In Germany the volunteer organization is presided over by an imperial commissioner or inspector-general, appointed in peace time, who in time of war is attached to the headquarters staff. His functions are to control the relations of the various Red Cross societies, and to secure their harmonious inter-working. Delegates appointed by him are attached to the various corps and transport commissions. No volunteer assistance can be utilized which is not entirely subordinated to the military control, and which has not already in peace time received official recognition, and been organized on a skeleton footing. Moreover, only persons of German nationality can be employed under it with the armies in the field. In the case of base hospitals situate in Germany itself, the services of foreigners may be enlisted by special permission of the war office. In France, in the main, the same rules obtain in the case of the volunteer hospital service.

Civil ambulances.—In 1878 the British ambulance association of St John of Jerusalem was founded. Its object was to render first aid to persons injured in accidents on the road, railway, or in any of the occupations of civil life. As a result of the initia-

tive taken by this society, ambulance corps have been formed in most large towns of the United Kingdom; and police, railway servants, and workmen have been instructed how to render "first aid" pending the arrival of a doctor (Fig. 4). This Samaritan work has been further developed and extended to most parts of the British Empire, notably to Canada, Australia, and India. In the United States the civil ambulance is not general. Each city has its own system and organization. In some the ambulance service is

FIG. 6.—Type of Motor Ambulance.

worked by the police, as in Boston; in others, notably New York, by the hospitals (Figs. 5, 6), whilst Chicago boasts an admirable ambulance service under municipal control. Apart from these "Samaritan" services, as they may be called, there is also in most of the larger cities of America a specially organized police ambulance for the rapid conveyance of arrested persons to the police stations. In most of the capitals of Europe there are likewise civil ambulance organizations dispensing "first aid" in urgent cases, but their *modus operandi* is in no special feature distinguishable from that of the ambulance association of St John.

(J. R. D.)

Amedeo Ferdinando Maria di Savoia,
DUKE OF AOSTA (1845-1890), third son of Victor Emmanuel II., king of Italy, and of Adelaide, archduchess of Austria, was born at Turin on 30th May 1845. Entering the army as captain in 1859 he fought through the campaign of 1866 with the rank of major-general, leading his brigade into action at Custoza and being wounded at Monte Torre. In May 1867 he married the Princess Maria Carlotta Del Pozzo della Cisterna. In 1868 he was created vice-admiral of the Italian navy, but, two years later, left Italy to ascend the Spanish throne, his reluctance to accept the invitation of the Cortes having been overridden by the Italian Cabinet. On 16th November 1870 he was proclaimed king of Spain by the Cortes; but, before he could arrive at Madrid, Marshal Prim, chief promoter of his candidature, was assassinated. Undeterred by rumours of a plot against his own life, Amedeo entered Madrid alone, riding at some distance from his suite to the church where Marshal Prim's body lay in state. His efforts as constitutional king were paralysed by the rivalry between the various Spanish factions, but with the approval of his father he rejected all idea of a *coup d'état*. Though warned of a plot against his life (18th August 1872) he refused to take precautions, and, while returning from Buen Retiro to Madrid in company with the queen, was repeatedly shot at in Via Arenal. The royal carriage was struck by several revolver and rifle bullets, the horses wounded, but its occupants escaped unhurt. A period of calm followed the outrage. On 11th February 1873, however, Amedeo, abandoned by his partisans and attacked more fiercely than ever by his opponents, signed his abdication. Upon returning to Italy he was cordially welcomed and reinstated in his former position. His consort, whose health had been

undermined by anxiety in Spain, died on 3rd November 1876. Not until 11th September 1888 did Amedeo contract his second marriage with his niece, Princess Letitia Bonaparte. Less than two years later (18th January

1890) he died at Turin in the arms of his elder brother, King Humbert I., leaving four children—the duke of Aosta, the Count of Turin, the duke of the Abruzzi, and the duke of Salemi. (H. W. S.)

A M E R I C A.

THE historical accident that resulted in the use of a single name, America, for the pair of continents that has a greater extension from north to south than any other continuous land area of the globe, has had some justification in recent years, since geological opinion has begun to turn in favour of the theory of the tetrahedral deformation of the earth's crust as affording explanation of the grouping of continents and oceans. America, broadening in the north as if to span the oceans by reaching to its neighbours on the east and west, tapering between vast oceans far to the south where the nearest land is in the little-known Antarctic regions, roughly presents the triangular outline that is to be expected from tetrahedral warping; and although greatly broken in the middle, and standing with the northern and southern parts out of a meridian line, America is nevertheless the best witness among the continents of to-day to the tetrahedral theory. There seems to be, however, not a unity but a duality in its plan of construction, for the two parts, North and South America, resemble each other not only in outline but, roughly speaking, in geological evolution also; and the resemblances thus discovered are the more remarkable when it is considered how extremely small is the probability that among all the possible combinations of ancient mountain systems, modern mountain systems, and plains, two continents out of five should present so many points of correspondence. Thus regarded, it becomes reasonable to suppose that North and South America have in a broad way been developed under a succession of somewhat similar strains in the earth's crust, and that they are, in so far, favourable witnesses to the theory that there is something individual in the plan of continental growth. The chief points of correspondence between these two great land masses, besides the southward tapering, are as follows:—(1) The areas of ancient fundamental rocks of the north-east (Laurentian highlands of North America, uplands of Guiana in South America), which have remained without significant deformation, although suffering various oscillations of level, since ancient geological times; (2) the highlands of the south-east (Appalachians and Brazilian highlands) with a north-east south-west crystalline axis near the ocean, followed by a belt of deformed and metamorphosed early Palæozoic strata, and adjoined farther inland by a dissected plateau of nearly horizontal later Palæozoic formations—all greatly denuded since the ancient deformation of the mountain axis, and seeming to owe their present altitude to broad uplifts of comparatively modern geological date; (3) the complex of younger mountains along the western side of the continents (Western highlands, or Cordilleras, of North America; Andean Cordilleras of South America) of geologically modern deformation and upheaval, with enclosed basins and abundant volcanic action, but each a system in itself, disconnected and not standing in alignment; (4) confluent lower lands between the highlands, giving river drainage to the north (Mackenzie, Orinoco), east (St Lawrence, Amazon), and south (Mississippi, La Plata). Differences of dimension and detail are numerous, but they do not suffice to mask what seems to be a resemblance in general plan. Indeed, some of the

chief contrasts of the two continents arise not so much from geological unlikeness as from their unsymmetrical situation with respect to the equator, whereby the northern one lies mostly in the temperate zone, while the southern one lies mostly in the torrid zone. North America is bathed in frigid waters around its broad northern shores; its mountains bear huge glaciers in the north-west; the outlying area of Greenland in the north-east is shrouded with ice; and in geologically recent times a vast ice-sheet has spread over its north-eastern third; while warm waters bring corals to its southern shores. South America has warm waters and corals on the north-east, and cold waters and glaciers only on its narrowing southern end. If the symmetry that is so noticeable in geological history had extended to climate as well, many geographical features might now present likenesses instead of contrasts.

When America is compared with the continents of the Old World, an important correspondence is found between its northern member and the greater part of Eurasia; but here the corresponding parts are reversed, right and left, like the two hands. The Laurentian highlands agree with Scandinavia and Finland, both having escaped deformation since very ancient times. A series of water bodies (the Great lakes in North America, the southern Baltic, with Onega, Ladoga, &c., in Europe) occupy depressions that are associated with the boundary between the very ancient lands and their less ancient covering strata. The old worn-down and re-elevated Appalachian mountains of south-eastern North America agree well with the Hercynian mountains of similar history in Middle Europe (Ardennes, Slate mountains of the middle Rhine, &c.), each range entering the Atlantic at one end (in Nova Scotia and Newfoundland; in Brittany, Wales, and Ireland), and dipping under younger formations at the other. Certain younger ranges—seldom recognized as mountains because they are mostly submerged in the American mediterraneans (Gulf of Mexico and Caribbean Sea), but of great absolute relief and with crests rising in the larger West Indian islands—may be compared with the younger ranges of southern Europe (Pyrenees, Alps, Caucasus) bordering the classic Mediterranean and the seas farther east. The central plains of North America correspond well with the plains of Russia and western Siberia; both stretch from great enclosed water bodies on the south to the Arctic Ocean, and both are built of undisturbed Palæozoic strata toward the axis of symmetry and of younger strata away from it. Finally, the Western highlands of North America may be compared with the great mountain complex of central and eastern Asia. In this remarkable succession of resemblances, we find one of the best proofs of the continental unity of Eurasia, however independently Europe and Asia should have been developed on a tetrahedral earth, and however fully the separation of these two grand divisions is demanded on historical and political grounds. Moreover, the resemblances thus described controvert the idea, prevalent when geology was less advanced than to-day, that the New World of civilised discovery is an "old world" geologically, and that the Old World of history is geologically "new." Both worlds are so old, and both share so well the effects of successive geological changes from the most ancient to

the most modern periods, that neither can regard the other as older or younger than itself. No simple generalization is admissible concerning the age of anything whose history is so complicated as that of a continent.

The climatic contrasts between North and South America are replaced by several climatic similarities between North America and Eurasia. The Appalachians and the Hercynian mountains of middle Europe both contain extensive coal deposits of similar geological age, thus indicating a climatic and geographic resemblance at a time of great antiquity. The Laurentian highlands and the Scandinavian highlands were both heavily and repeatedly glaciated in recent geological times, and the ice sheets that crept out on all sides from those centres spread far over the lower lands to the south and away from the axis of symmetry towards the continental interior, scouring the central highlands and leaving them rocky and barren, strewing extensive drift deposits over the peripheral areas, and thus significantly modifying their form and drainage; while the much loftier mountain ranges of western America and central Asia suffered, singularly enough, a far less extensive glaciation. At the present time, the plentiful and well-distributed rainfall of the continental border on either side of the Atlantic is succeeded by an increasing aridity towards the continental interior, until the broad plains that rise towards the distant mountain complexes are comparatively barren or even desert. Within each greater mountain area extensive interior drainage basins are found holding salt lakes, and the suspected former extension of these lakes in central Asia agrees well with the proved extension of the lacustrine conditions in western North America. In matters of temperature, however, there are certain contrasts, as will be more fully stated below when the question of climate is discussed.

NORTH AMERICA.

The following sketch of the geological development of North America considers the larger physiographic divisions in the order already presented.

The extensive area of ancient crystalline rocks (Archæan), stretching from Labrador past Hudson Bay to the Arctic Ocean, is of greatly disordered structure, and hence must have once had a mountainous form. Moreover, the crystalline texture and deformed foliation of the rocks prove that the surface now seen was once buried deep beneath the surface of an earlier time, for only at great depths can such texture and foliation be acquired. Both these lines of evidence lead to the conclusion that the moderate relief prevalent over the existing Laurentian region is the work of persevering erosion during a long continuance of dry land conditions, and hence that the region must be regarded as one of those worn-down mountain systems which so eloquently testify to the vast duration of geological time. But the full value of this testimony is appreciated only when it is discovered that the worn-down old land is gently overlapped, chiefly around the south and west, and south of Hudson Bay, by very early Palæozoic strata which rest upon the eroded surface of the crystallines, thus proving that the destruction of the ancient mountains had already been accomplished before some of the oldest fossiliferous formations of the world had been deposited. All the evidence goes to prove that from then to now the Laurentian region has been relatively quiescent, as if the forces of deformation had been exhausted by their efforts in the earlier ages of the earth's history. In all subsequent time there have been here no such great crushings and upheavals as have occurred elsewhere, but only moderate

Laurentian highlands.

oscillations of level, one of which allowed the transgression of the ancient sea in which the overlapping strata were deposited, while another of much more modern date gave the region its present highland altitude (1000 to 2000 feet; mountains near the Labrador coast, 8000 feet), again offering it to the forces of erosion.

It is this ancient Laurentian area that the earlier geologists named the "Continental Nucleus," as if it had been the first part of North America to rise from the primeval waters of an assumed universal ocean. The "Archæan V," formed by the two arms of the Laurentian oldland stretching from Labrador to the Arctic, between which Hudson Bay is included, has been repeatedly described as the oldest area of the continent, the beginning around which many later additions have built the existing outlines; and as such it has been adduced in favour of the theory of the permanence of continents. But when thus stated, the half of the story in favour of this theory is not told. Hudson Bay is not due to a primitive failure of elevation between the arms of the "Archæan V"; it is not a deep basin whose floor has never emerged from the primeval ocean, but an ancient and comparatively shallow depression in a pre-existent land, over which the sea flowed as the surface sank below sea-level. South and west from the "Archæan Nucleus," the Cambrian strata of the medial plains of North America are found to lie, wherever their base is discovered, on a foundation that possesses all the essential features of the Laurentian oldland. This relation is found all around the Adirondack mountains in New York, along the Appalachians southward to Georgia, through the Mississippi basin in Wisconsin and Missouri, and beyond in Texas, and farther west in the Black Hills, as well as certain points in the Rocky Mountains region. Hence the pre-Cambrian land surface of the continent must have had not only a vastly greater area than was formerly attributed to it, but also an earlier origin; for at the time when it was thought by the older geologists to be first rising from the primeval ocean, it is now proved to have been slowly sinking after a prolonged land existence. The crystalline Archæan rocks in the Laurentian region and its scattered fellows cannot possibly be explained as a primitive sea bottom, rising above sea-level to make the beginning of a continent and receiving Cambrian strata upon its still submerged borders, but only as portions of an already old and deeply-denuded land area, which was in pre-Cambrian time much larger than the visible Laurentian area of to-day, and which was reduced to perhaps half its primeval dimensions by a gradual submergence beneath the transgressing sea in which the Cambrian sediments were laid down. We are thus led to believe that much of the continent of to-day was a continent in the earliest geological times, and that the seas which partly covered it in Palæozoic and Mesozoic time were due to partial submergence, not to partial emergence. Furthermore, all the marine strata that now stretch over a large part of what is believed to have been the ancient continental surface are of relatively shallow water origin; none of them bear any close resemblance to the deposits of the deep oceans that have been so well studied in the last thirty years. Hence the Palæozoic and Mesozoic seas of North America were not deep oceans, and as far as this continent is concerned it is by no means admissible to assume, as some of the earlier geologists did, that the position of continents and oceans have repeatedly changed places. The testimony of the rocks is decidedly in favour of Dana's view that continental masses are relatively permanent, and hence also, as far as stability is concerned, in favour of the theory of a tetrahedral earth.

The early history of the Laurentian region has been

dwelt upon because of its great importance in the history of the continent, and because its history has so generally been misunderstood. To these reasons may be added a third: through Palæozoic and Mesozoic time the history of the Laurentian region is for the most part a blank. Records are wanting from the early Palæozoic to the Pleis-

tocene, when the Laurentian uplands became the centres from which the ice sheets of the Glacial period spread out on all sides. As a result of this late chapter in the history of the region, the weathered soils of earlier periods were swept away along with an unknown amount of firm rock, leaving bare ledges, scattered boulders, and gravelly drift

SKETCH MAP OF NORTH AMERICA.

London: Stanford's Geog. Estab.

to-day upon a rugged upland without mountains (except in north-east Labrador), but diversified by innumerable knobs and hollows. The drainage of the region has thus been thrown into disorder; large and small lakes and marshy hollows abound; the streams are repeatedly interrupted by rapids, and frequently split into two or more channels, enclosing islands many miles in length. They are the only highways of this thinly inhabited region.

The Appalachian province is a generally hilly and mountainous belt, stretching from Newfoundland to Alabama. It seems for the most part to have belonged in the earliest times to the great pre-Cambrian land area, of which the Laurentian highland is the more manifest representative; for wherever the basal members of the Palæozoic sedimentary series are found in the Appalachians, they rest upon a floor of

Appalachian highlands.

denuded Archæan rocks, and the lowest layers are largely composed of Archæan detritus. This province must, however, be set aside from the undisturbed Laurentian region because of the repeated movements of depression, deformation, and elevation that it has suffered, generally along a north-east south-west trend, causing the successive alternations of heavy deposition, and almost equally heavy denudation, that have prevailed with varying intensity during the whole stretch of geological time covered by the fossiliferous record. The earliest important mountain-making disturbances interrupted the conditions of deposition in Cambrian time, and produced what has been called the Green Mountain system. A later, and probably greater, disturbance, with its climax at the close of Carboniferous time, established the Appalachian Mountain system; but, as understood to-day, the "Appalachian revolution" of the older geologists should be regarded as a long-lasting process, perhaps intermittently enduring as long as the whole of Carboniferous time. A subordinate period of deposition and deformation occurred early in Mesozoic time, marked by the accumulation and disturbance of several basins of the Newark formation, roughly corresponding to the Triassic of Europe.

The Appalachian mountains of to-day were formerly regarded as the unconsumed remnants of the chief Appalachian uplift; but it is now generally agreed that Mesozoic erosion reduced the greater part of the range to a lowland of moderate or small relief, leaving only isolated groups of subdued mountains in the areas of the most resistant rocks, and that the altitude and form of the mountains are chiefly the result of the Tertiary elevation and dissection of the previously worn-down mass,—the additional height thus given in Tertiary time to the pre-existent subdued mountain groups making them now the loftiest areas of the range, as in the White Mountains of New Hampshire (Mount Washington, 6293 feet), and the Black Mountains of North Carolina (Mount Mitchell, 6711 feet). It is interesting to note that the axis of Tertiary elevation is nearly parallel to and closely associated with the axes of the earlier disturbances, but it lies somewhat to the north-west of its predecessors, and therefore involves considerable areas of flat-lying Palæozoic strata on the inner side of the previously disturbed belt from New York to Alabama, thus producing what is known as the Allegheny plateau (altitudes, 2000 to 4000 feet). It should be added that the Osark plateau of Missouri and the Ouachita mountains on the south in Arkansas and farther west are related to one another in much the same way as the Allegheny plateau and the middle ranges of the Appalachians—the two pairs corresponding to a remarkable degree in regard to conditions of ancient accumulation, mediæval deformation and denudation, and more modern uplift and dissection; it is, therefore, admissible to classify this western group of uplifts as an annex to the normal Appalachians. Numerous and extensive coal seams occur in the worn-down Appalachians of Nova Scotia, Pennsylvania, and Alabama, as well as in the Allegheny plateau from Pennsylvania to Alabama, and in the extension of the same strata through the Ohio and middle Mississippi basins.

The eastern coast of the continent has a ragged shore line from Maine to Greenland, with numerous submerged lowlands and valleys forming bays, and as many uplands and ridges outstretching in promontories and islands; this being the result of the summation of many movements of the land, whose total gives an increasing measure of depression to the north where an archipelago at last replaces what was probably once a corner of the continent; but the measure of the depression is uncertain, because of the doubt regarding the depth beneath sea-level to which the Pleistocene glaciers may have

worn the pre-Glacial valleys. South of New England, along the Atlantic coast, and around the border of the gulf into Mexico, the dominating movement of the land in late geological periods has been upward with respect to sea-level, whereby a former sea bottom, on which the land waste of Cretaceous and Tertiary times had been outspread, was revealed as a coastal plain, across which the rivers of the former land area now extend their courses, from the old shore line to the new. Part of the same plain, still submerged, forms the "continental shelf" of the mid-Atlantic border. Florida seems to be a projecting swell of this shelf, around whose extremity coral reefs have been added, but whose greater mass is still under a shallow sea cover. Along the ragged coast in the north a moderate and very modern movement of elevation has laid bare clay-floored lowlands that were lately beneath the sea, as in the plain of the lower St Lawrence valley, while along the coastal plain of the south a slight movement of depression has drowned a number of low valley floors, producing shallow arms of the sea, as Chesapeake Bay, Albemarle and Pamlico Sound, and Mobile Bay.

The great complex of mountains in the Western highlands, sometimes styled the Cordilleras of North America (the Rocky Mountains being the eastern members of the system in the United States and Canada), differ from the Laurentian and Appalachian regions in having suffered numerous disorderly movements at dates so recent that the existing relief of the region bears a significant relation to its irregular uplifts; a relation that doubtless once obtained in the older mountain areas of the east, where it has now been obliterated by erosion. It is not, however, only in modern geological periods that mountain-making disturbances have prevailed in the regions of the Western highlands; their geological history is one of repeated and long continued movement—the ruins of the more ancient upheavals supplying materials for the strata of newer ranges. For example, in Canada an axial belt of ancient rocks is bordered on the east and west by stratified formations of enormous thickness (40,000 to 60,000 feet), those on the west including a large share of contemporaneous volcanic materials; all three belts having been deformed and upheaved, as well as deeply dissected in the later chapters of geological time. It is, however, important to note that the interval between Palæozoic and Mesozoic time, in which mountain-making disturbances were so general in western Europe and eastern North America that the older geologists thought them to be of world-wide extent, was here generally passed over in relative quiet, so that continuous sedimentation produced in certain districts a conformable series of deposits from Silurian to Cretaceous time. Furthermore, the Carboniferous period, which gained its name from the extensive coal deposits that were then formed in western Europe and eastern North America, was a marine limestone-making period in the Cordilleran region. If the science of geology had had its origin on the Pacific side of America, some of its early generalizations would have been very different from those which gained credence in the lands bordering the North Atlantic.

There is here exemplified, as might be expected in a region extending over 3000 miles from Alaska to southern Mexico, and measuring over 1000 miles in breadth at its middle, a great variety of plateau and mountain structures. The broad upheaval of adjacent blocks of earth-crust without significant tilting or disturbance has produced the plateaus of Arizona and Utah. Some of the simplest and youngest mountain ridges in the world are to be found in the broken and tilted lava blocks of southern Oregon. Tilted blocks on a larger scale, much more affected by processes of sculpture, are found in the lofty St Elias Alps of Alaska, the site of some of the

The Cordilleras of North America.

greatest glaciers in the world. The wall of a huge fracture, now elaborately carved, constitutes the western slope of the Wahsatch range, facing the desert basin of Utah. Ranges of a relatively simple arch structure are seen in the Uinta mountains of Wyoming and Utah. Arched upheavals also characterize the front range of the Rocky Mountains proper in Colorado and Wyoming and in the Black Hills of South Dakota, bending up the strata of the adjacent plains in the simplest fashion, and producing dome-like mountains, now deeply dissected by outflowing consequent streams. A remarkable change occurs in the structure of the Rocky Mountains north of the Missouri river in Montana and northward into Canada, where the front range is of synclinal or trough structure, with the youngest instead of the oldest rocks along the axis, while the strata of the plains are bent down and overridden in the most abnormal manner. Indeed, mountain structure occurs of so great diversity in various parts of the Cordilleran region as to elude general description. The disturbances extend directly to the western coast line, including not only the coast range of California, but the peninsular area of Lower California (belonging to Mexico) and the detached mountainous islands of British Columbia and Alaska.

Volcanoes of commanding form here and there dominate the plateaus and mountains. Orizaba, Popocatepetl and their neighbours, terminating the Cordilleran system in Mexico; Mount San Francisco, bearing snow and Arctic plants above the nearly desert plateau of Arizona; Mount Shasta, with small glaciers in northern California; Mount Rainier, with extensive glaciers surmounting the Cascade range of Washington; Mount Wrangell in Alaska, and farther on the many cones in the curved chain of the Aleutian islands: all these have been heaped up around vents through which their lavas rose from some deep source. Vast lava floods have been poured out at different times. Extensive lava beds, barren and rugged, cover large areas in north-eastern California. The basins of Snake and Columbia rivers in Idaho and Washington are flooded with older and more extensive lava sheets, whose borders are varied by promontories and islands of the "mainland." Still older lava flows in British Columbia are now deeply dissected by the branches of Frazer river, and remain only in disconnected upland areas. High plateaus in Utah are protected by a heavy lava capping, the result of great eruptions before the plateaus were uplifted. Here and there rise dome-like mountains, the result of the underground intrusion of lavas in cistern-like spaces, forming "laccoliths," and blistering up the overlying strata. Thus, by mountain upheaval or volcanic eruption, great altitudes have been gained. Where the uplift has been strong, ranges of truly Alpine form with extensive snow-fields and glaciers occur, as in the Selkirk range of Canada (now traversed by the Canadian Pacific railway), and again in Alaska. Heights of 12,000 and 14,000 feet are exceeded by numerous summits in the central part of the system; but the dominating peaks are found far in the north-west and in the south. Several mountains in Alaska exceed 18,000 feet (Mount McKinley, 20,464 feet; Mount Logan, 19,500 feet; Mount St Elias, 18,024 feet); and the great Mexican volcanoes rise nearly as high (Orizaba, 18,250 feet). Widespread plateaus maintain upland altitudes of more than a mile over vast areas.

As in all regions of great altitude, the erosion of valleys has progressed on a magnificent scale in the Cordilleran region, and the actual form of many of its parts is more the result of sculpturing than of uplifting. The plateaus of Arizona are traversed by the deep cañons of the Colorado river and its branches, at places a mile deep; and with elaborately carved walls, from which the

most impressive lessons have been learned regarding the origin of valleys by river action. Upon the plateaus themselves, long and ragged cliffs of recession attest an even greater work of erosion than the cañons. In all the mountain ranges except those of youngest uplift, valleys have been actively eroded, sometimes producing steep peaks as in Mount Assiniboine (11,500 feet) in the Canadian Rockies, rivalling the Swiss Matterhorn in sharpness of form; but the greater number of summits have been worn to roughly pyramidal form between wide-flaring valleys, and the mountain flanks have thus come to be extensively covered with rock waste lying on slopes of relatively uniform declivity. Some of the ranges are in a second cycle of dissection, having been once worn down to moderate relief and now being elevated for renewed erosion; the Sierra Nevada of California is believed to be, in part, of this history, having at least in its central and northern parts been well reduced and now again enjoying a mountainous character in virtue of a later slanting uplift *en bloc*, with rapid descent on its eastern fractured face. Other ranges, almost completely worn down, still remain low, as in south-eastern California, where they are now represented by gently sloping rock floors veneered with gravel and retaining only small remnants of their original mass still unconsumed; thus the end, as well as the beginning, of the cycle of erosion, together with many complications of its progress, are illustrated in different parts of this great and varied mountain system. In the fiorded coast of Alaska, signs of intense glacial erosion are seen in the discordant junction of the "hanging" lateral valleys and the deep trunk valleys—the floors of the former being cut off on the walls of the latter.

Fitting complements of the deeply-eroded mountains are found in the great accumulations of mountain waste now occupying basins of depression between the various ranges, as in Mexico, Utah, Nevada, Montana, and elsewhere. Erosion and transportation here combine to build up the floors of the basins with the waste of the surrounding highlands; a result that is peculiarly beneficial in Mexico, where the climate of the plateau basin is rendered relatively temperate by reason of its altitude, and where the surface is easily habitable by reason of its smoothness. In the larger depressions, as along the boundary of the United States and Mexico, isolated ranges frequently rise like islands over the plain of waste that has been built up on their flanks. Shallow saline lakes or playas (wet-weather lakes) without outlets lie on the lowest parts of the waste-filled basins; their failure to overflow in rivers discharging to the sea being less the result of enclosure by barriers than of deficiency of rainfall; for it is chiefly in the arid region that the waste-floored basins are best developed. Indeed, the rainfall is often so scanty that the streams from the mountains—where most of the little precipitation occurs—often fail even to form lakes, withering away on the waste plains. In all these cases, the wash of rock waste from the mountains remains on the continent and builds up the basin plains, instead of being carried away from the land to form stratified sediments on the sea floor. The habit of gathering mountain waste in interior basins that characterizes so much of the Cordilleran region to-day is only the continuation of an earlier practice, for extensive basin deposits of Tertiary date are found in many parts of the Cordilleran region; some of them are famous for preserving vertebrate fossils, such as those of the many-toed ancestors of the horse.

Between the loftier Western highlands and the lower Eastern highlands (Laurentian and Appalachian) lies a great extension of Medial plains, stretching in moderate altitude from the Arctic Ocean to the Gulf of Mexico,

and having in their middle a breadth of 1500 miles. They are composed throughout of nearly horizontal strata and mark a region long exempt from strong disturbance. Although for the most part flooded by marine formations, their structure and composition indicate, as has already been said, relatively shallow water. The ancient sea that once occupied the middle belt of the continent therefore had little likeness to the abysmal oceans, but resembled rather the shallow ocean margins that to-day overlap various continental masses—the largest example of this kind now existing being between Asia and Australia. The eastern part of the plains is underlaid by Palæozoic strata, already mentioned as having been laid down upon the subsiding Archæan continent or folded in the making of the Appalachians; coal beds are here included in the Ohio and middle Mississippi basins. The area of the western plains remained submerged to a later date, preserving a stretch of marine waters to the end of Mesozoic time, and thus resembling the lowland belt of western Asia, which was similarly covered by a broad and a shallow arm of the ocean extending from the Arctic to the European mediterraneans until a late geological date. The surface of the Medial plains is not always so even as might be inferred from their name. Both the eastern and the western areas have been extensively denuded, even to the point of being reduced to lowlands of denudation. Their present altitude is not so much the result of their original uplift from the sea as of a later elevatory movement. The great river basins, for which North America is famous, have thus been formed between the Eastern and Western highlands—the Mississippi receiving the drainage of a vast area (about 1,240,000 square miles) for discharge to the south, while the Saskatchewan and Mackenzie gather their waters from somewhat less extensive areas in the north. Pleistocene glaciation covered the plains of the Ohio, upper Mississippi and Winnipeg districts with extensive deposits of ice-laid or water-laid drift, furnishing a generally smooth surface and a fertile soil: here are the true prairies—treeless, but richly grassed.

The traditional continuity of the Cordilleras of North and South America has been broken by investigations in the isthmian portion of the northern continent.

Central America and the West Indies.

The structural peculiarities of the Western highlands of North America may be traced only to the east and west belt of great volcanoes by which the plateau of central Mexico is terminated on the south. The ranges of the Andes fail to reach Panama, from which the nearest one is separated by the valley of the Atrato. The two Cordilleras are out of line with each other, and their ends are some 1200 miles apart. Central America, the West Indies, and various submarine ridges by which they are connected with one another and with the mainland to the west, as well as certain ranges along the northern margin of South America, all belong together in what has been termed the Antillean mountain system, in which east and west trends of late geological date predominate, with abundant volcanic additions on the Pacific border of Central America, and along the eastern end of the system in the Windward islands of the Lesser Antilles. The unity of this system has been until recently overlooked partly because the Antillean ranges are for the most part still under water, and yet further because the volcanoes which form the strongest reliefs of the isthmian region are so arranged along the Pacific coast as to suggest the continuity of the Cordilleran systems on the north and south; but these volcanoes are really only superadded to a foundation of quite another kind. Geological studies on the mainland and on the islands have shown that both fundamental

structure and surface form are not Cordilleran; and numerous soundings in the adjacent mediterraneans suggest that the islands are best interpreted as the somewhat denuded crests of great crustal ridges. The warm waters that bathe the West Indies come with a high temperature from the equatorial Atlantic, and favour the growth of corals along the shores. Fringing and elevated reefs are known on many of the islands. The Bahamas are the slightly overtopping parts of a broad platform of coral and other calcareous marine deposits, of which the greater area constitutes extensive shallow banks, which descend by a steep slope on the north-east to great depths in the Atlantic. The lowlands of Yucatan resemble Florida in being the emerged part of a much larger mass, of which an equal portion is still under water in the shelf around the Gulf of Mexico. All this region is luxuriantly productive and is advantageously surrounded by waters which would be barren and desert if replaced by lowlands. The active volcanoes on the Pacific slope have built many cones and uplands, some of their historic eruptions having been of terrible violence. Thus Lake Nicaragua, once a bay of the Pacific, has been cut off by volcanic deposits, leaving only the Gulf of Fonseca open to the western ocean, raising the level of the lake behind the barrier and turning its discharge eastward to the Caribbean Sea across what was once the inter-oceanic watershed.

The successive crustal movements by which the land area of what we now know as North America has been increased and connected have determined the growth of several great river systems through **Rivers.** which the broader part of the continent is drained. The movements that resulted in the emergence of the Plains had the effect of engrafting many ancient rivers of moderate size upon trunks of unusual dimensions. The Mississippi system, some of whose eastern branches probably date from early Mesozoic time, received great reinforcements by the addition of many long western branches in Tertiary time, roughly contemporaneous with the uplift of the Gulf coastal plain by which the lower trunk of the river was extended to the sea. The present headwaters of that stream to which the name of Mississippi is applied, and which for that reason have gained an undue subjective importance, are of relatively modern date, as they are controlled by the abundant glacial deposits of northern Minnesota. The evolution of the Mackenzie resembles that of the Mississippi in a very general way, although some of its eastern branches may be the descendants of ancestors more ancient than those flowing westward from the Appalachians; but the régime of the great northern river is strikingly unlike that of its still greater southern analogue on account of its course being from a warmer to a colder climate: hence ice-dams, obstructed discharge, and overflows. The Nelson and the St Lawrence systems, draining eastward to Hudson Bay and St Lawrence Gulf, receive drainage from areas that would belong to the Mackenzie and the Mississippi systems under a simpler plan of continental growth; and there is much reason for thinking that this simpler plan obtained until the occurrence of those changes, in association with the Glacial period, whereby sea waters gained access to the depressions that now hold the bays and sounds of the north-eastern coast. In exemplification of the rule that the larger ocean receives the drainage of the smaller continental area, the rivers that flow into the Pacific rank below those belonging to the Atlantic. The greatest is the Yukon, of farther Canada and inner Alaska, one of the great rivers of the world, little known until the recent active exploration of its basin for gold fields. The Frazer drains much of the mountainous area of Southern British Columbia, as the Columbia drains that of the north-western United States;

the latter is peculiar in that one of its headwaters rises at the eastern base of the Rocky Mountains in northern Montana. The Colorado discharges a muddy current into the Gulf of California; but for the aridity of its large drainage area its volume would be much larger. The same is true of the Rio Grande, whose name would be better justified if so much of its basin were not semi-arid.

The references already made to lakes may now be reviewed and summarized. Several lake districts may be

Lakes. mentioned. The most remarkable lacustrine region of the continent, rivalling that of central Africa, forms a belt around the border of the Laurentian highland; here, in addition to ten large lakes, there are hundreds of medium size, and many thousand small lakes. They are peculiar in occupying a region of moderate relief, in which no strong dislocations have taken place in recent geological time (unless in the case of Lake Superior), and thus in contrasting with the great African lakes which occupy rift-valleys or *graben* of comparatively recent fracture. The Laurentian lakes are further characterized by an intimate association with the ice-sheets of the Glacial period; but while glacial erosion and drift obstruction suffice to account for the smaller lakes, it is very probable that broad crustal warping and drainage reversal have been potent aids to the other processes in producing the great lakes. The northern Cordilleran region contains many beautiful lakes of moderate size in deep valleys among the crowded ranges of the narrowed mountain belt. Their origin has not been closely studied. The basins among the spaced ranges of the middle and southern Cordilleras, in the United States and Mexico, contain many lakes that occupy shallow depressions in desert plains; they are usually without outlet and saline; many of the basins were formerly occupied by lakes of much greater size, some of which overflowed, implying a climate moister than that of to-day, probably correlated with the glacial climate of the regions farther north. Lakes in volcanic craters or behind volcanic barriers occur in Central America, while Florida possesses many small lakes in limestone basins. The following table is taken from Russell's *Lakes of North America*:—

Lake.	Altitude.	Area.	Depth.
	Feet.	Square Miles.	Feet.
Ontario	247	7,200(?)	738
Erie	573	9,900	210
Huron	582	22,322	750
Michigan	582	21,729	870
Superior	602	31,000(?)	1008

The climatic features of North America are best appreciated when considered as exhibiting modifications

of those general climatic conditions which prevail in consequence of the globular form of the earth as a whole. In January, when the isotherms of 65° to 75° F. stretch almost directly across land and sea in the torrid zone, a mean temperature of zero or less invades the region north-west of Hudson Bay, which thus resembles north-eastern Asia in departing greatly from the mean prevailing in similar latitudes on the northern oceans, and in bringing upon the northern lands an extension of frigid conditions that have no analogue in the southern or oceanic hemisphere. In July, when the isotherms of 40° and 50° have a tolerably direct course around the latitude circles that border the continent on the north, a great middle area of North America becomes warmer than the seas on the east and west, having a mean of over 80°, and in part over 90°. In January, the Hudson Bay region is 30° colder than the mean of its own latitude, about 60° colder than the mean of the corresponding southern

latitude; while in July the Arizona-Mexican region is 20° above the mean of its own latitude, or about 40° above the mean of the corresponding southern latitude. In both winter and summer the isotherms are more closely crowded while crossing the continent than while crossing the adjacent oceans; or, in other words, the poleward temperature gradient is stronger on the land than on the oceans; and all these features should be regarded as inherent characteristics of the climate of North America in virtue of its being a continent chiefly in temperate latitudes.

An associated feature of continental climate is found in the strong annual range of temperature of the central land area. The range between the means of January and July exceeds 40° for the largest part of the lands, and 70° for much of the northern lands; the range of extreme temperatures is much greater. On corresponding oceanic areas in the northern hemisphere the range is little more than 20°, and in the southern hemisphere it is probably less than 10°. It must appear from this that if the largest part of North America is said to be in the north temperate zone, "temperate" must be taken as having little of the meaning originally given to it in southern Europe, for the winter cold is severe and the summer heat is excessive over much of the North American continent. In this respect two more unlike belts can hardly be found than the north and south temperate zones, in spite of the resemblance that is implied in their names.

The several members of the terrestrial wind system, including therein the trade winds of a broadened torrid zone, the stormy westerly winds of middle latitudes, and the irregular winds of the polar regions, are well exemplified over North America; but, as is usually the case on land, the systematic movement of the atmosphere is better seen in the drift of the clouds than in the movement of the surface winds, which are much modified by the changes from hill to valley, from mountain to plain. Nevertheless the prevalence of the general atmosphere currents has much to do with the control of certain values of annual temperature range, as well as with the distribution of rainfall. The former are small (about 20°) along a great stretch of the Pacific coast, even as far north as Alaska, where the moderating influences of the ocean are brought upon the land by the westerly winds; while a range appropriate to a continental interior (30° or 40°) is experienced over most of the eastern side of the continent in temperate latitudes, and even upon the North Atlantic ocean near the American coast, where strong seasonal changes of temperature are carried forward by the westerly winds. It is particularly in this respect that the general climatic resemblances between North America and Eurasia, above referred to, are broken; for eastern Canada and western Europe are strikingly unlike in seasonal variations of temperature. Labrador is about 10° cooler than northern Germany in July, but nearly 40° colder in January.

The distribution of rainfall is in general controlled by the prevailing course of the winds. The West Indies receive abundant rain from the passing trades. In Mexico and Central America the eastern slopes are for the most part better watered than the western, because the winds there come chiefly from the east (maximum over 100 in. in Guatemala and adjacent parts). Farther north the reverse holds true; the Pacific slope north of 40° latitude has an abundant rainfall (maximum over 100 in.), and its mountains are clothed with dense forests. There are large areas of deficient rainfall (less than 20 in.) in the interior of the continent, where the intermontane basins and the piedmontese plains that slope eastward from the Rocky Mountains in middle latitudes are treeless. The areas afflicted with dryness are unsymmetrically distributed, being west

of the Medial meridian (95°), because of the ranges near the Pacific by which rain is withheld from the basins and from the plains farther east. The dryness is induced not only by light precipitation, but also by active evaporation in the warm season—a rule that holds true until a high latitude is reached. East of the medial meridian great profit is received from the warm and moist winds that are drawn inland from the water surface of the mediterraneans which so advantageously occupy the latitudes that are given up to the Sahara in the Old World. It is largely on this account that the central and eastern parts of the Mississippi basin enjoy a sufficient and well-distributed rainfall, producing forests or fertile prairies over great areas (rainfall over 40 in.). Regions of prevailing snowfall are chiefly in the north-west and north-east; the former includes the higher ranges of the Western highlands in Canada and Alaska, where the snowfall from the Pacific winds is heavy, and extensive snowfields and glaciers are formed; the former includes Greenland, where a heavy ice-sheet shrouds the land, the snowfall of moderate measure being probably supplied mostly from the relatively warm waters of the North Atlantic. In the northern continental interior snow covers the ground during the winter season, not that the snowfall is heavy but that the persistent cold weather preserves the moderate amount that falls.

The extension of the continent across the belts of the terrestrial wind system tends to turn branch winds from the westerlies toward the trades on the Pacific border, and from the trades toward the westerlies on the Atlantic border. This effect is strengthened in summer, when the higher temperature prevalent over the continent causes the air to flow away from above the lands, and to accumulate over the neighbouring oceans, on each of which a vast anticyclone is thereby established,—the circulation of the atmosphere over the North Atlantic and North Pacific thus coming to simulate the circulation of the surface waters of the oceans themselves. It is partly on account of this deflection of the summer winds up the Mississippi valley that the eastern interior of the continent receives a beneficent rainfall as already stated. In winter when the inflow from the south is replaced by an outflow, little rain or snow would fall but for the indraft winds of cyclonic storms by which the outflow appropriate to the cold season of the continent is temporarily reversed. The free play of the winds north and south over the great Medial plains permits indrafts from torrid and frigid sources, which sometimes succeed each other rapidly, producing abrupt and frequent weather changes. Something of the same contrasts is produced by winds drawn in upon the eastern coast alternately from over the moist and warm waters of the Gulf Stream, and from over the moist and cold waters of the Labrador current.

The southerly flow of the branching winds along the Pacific coast gives them a drying quality, and thus still further broadens the western arid region towards the ocean until it reaches the coast in southern California and north-western Mexico (rainfall less than 10 in.), there joining the arid belt of western Mexico, and presenting a strong contrast to the rainy forested coast farther north; but although unfavourably dry, the southern California coast is one of the most truly temperate regions of the world, in respect of mildness and constancy of temperature. The drying winds cover all California in summer, but they migrate southward in the winter, giving place to the stormy westerlies. Thus California has a subtropical climate of wet winters and dry summers; while north in British Columbia and Alaska there is plentiful rainfall all the year round, and farther south there is persistent aridity.

The fauna of North America (Nearctic) is more closely related to that of Europe-Asia (Palæartic) than to that of any other zoogeographical province; the two being united by many writers in one faunal province (Holarctic). Fauna. The reindeer (caribou), beaver, and polar bear are common to both provinces. The moose, wapiti, bison, and grizzly bear of North America are closely related to the elk, red deer or stag, aurochs, and brown bear of Eurasia; and the following groups are well represented in both provinces: cats, lynxes, weasels, bears, wolves, foxes, seals, hares, squirrels, marmots, lemming, sheep, and deer. On the other hand, the following forms are characteristic of North America: (*rodents*) pouched rats or gophers, musk rat, prairie dog, Canadian porcupine; (*carnivora*) raccoon and skunk; (*ungulates*) musk ox, bighorn, Rocky Mountains goat, pronghorn; (*marsupial*) opossum. Among birds there is a close resemblance to those of Eurasia, with some admixture of South American forms, as in the humming birds. The forms especially characteristic of the northern continent are the Baltimore oriole, bobolink, cowbird, flycatchers, wood-warblers, Californian quail, tree grouse, sage grouse, wild turkey, and turkey buzzard. The house sparrow of Europe has been introduced, and has become very common, especially in the cities, where it is known as the English sparrow. Reptilian and amphibian groups are well represented; turtles are especially numerous; salamanders are varied and large; rattlesnakes are among the more peculiar forms. Among fish, the characteristic forms are the cyprinoids (carp), sturgeon, salmon, pike, and especially the suckers, sunfish, mudfish (*Amia*), and gar pike (*Lepidosteus*). The most characteristic group of invertebrates is the Unionidæ or river mussels.

The floral areas of North America, limited by the geographic divisions of the continent, may be divided into five belts: the eastern forested area, the western forested area, the interior unforested area, the northern barren lands, and the Gulf coast. Flora. The eastern forested area extends from the Laurentian highland in Canada to the Great lakes, and southward east of the Mississippi to the Gulf coast. In the north and along the mountains southward, the forests are largely coniferous, with a mixture of birches, poplars, and maples. Southward, especially in the interior and at low altitudes, the conifers largely disappear, and oaks, hickories, plane-trees, tulip-trees, walnuts, and other valuable deciduous species abound. Throughout this belt lumbering is an important industry. The western forested area begins in the eastern Rocky Mountains, and extends to the Pacific. Eastward in the mountains the forests are interspersed with arid districts which increase in area southward. Northward, in Canada, the mountains of the middle Cordilleras are densely wooded with continuous forest. Near the middle Pacific coast the forests attain a luxuriant development, the redwood (*Sequoia*) of California and Oregon sometimes reaching a height of from 300 to 400 feet. In this western forested area lumbering is extensively carried on. The unforested area of the interior consists of two very dissimilar portions. The vast fertile prairies extend from the Great lakes westward to the Great plains, and southward west of the Mississippi, with occasional eastward lobes at low altitudes. On these plains grasses and other herbaceous vegetation abound, and throughout this fertile belt agriculture is largely followed, the grain and hay crops being especially important. Northward in Canada the plains become wooded, the western mountains and the eastern highlands being thus connected by a narrow strip of forest. South-westward and westward the fertile prairie gives way to a vast arid region beginning on the Great plains and extending as far as south-eastern California, and thence south-

ward into Mexico. On this broad desert few trees are found, although piñons grow on the cliffs and ledges, and cottonwoods occur along the watercourses. The vegetation as a whole consists of cacti, agaves, sage-brush (*Artemisia*), and other plants adapted to arid conditions. North of the eastern forested area and east of the northern Cordillera are the "barren lands," with frozen subsoil, extending thence to the Arctic coast. The growing season here is short and the climate forbidding, so that trees cannot develop, although birches, poplars, willows, and other genera, which southward attain great size, are present as dwarf shrubs. The vegetation of this northern barren district, like that of bleak mountain summits southward, is very similar in character to that of other extreme boreal regions. Blueberries, crowberries, and some other small fruits are abundant, but the brief summer will not mature most crops of the temperate zone. The Gulf coast, on the other hand, supports a vegetation decidedly tropical in its nature. Somewhat developed in Florida and the other southern states, this flora becomes the prevailing one on the coast of Mexico and Central America, especially from the region of Vera Cruz southward, where the forests are largely composed of palms and live oaks, and where giant bamboos often attain a height of 40 feet. In these tropical forests many orchids and other showy plants of northern conservatories are native.

North America, with an area of about 8,000,000 square miles (16 per cent. of all the lands, or 4.12 per cent. of the whole earth's surface), and a mean altitude of about 2000 feet, at present plays a part in human history that is of greater importance than is warranted by its size alone, although it has not in this respect the extraordinary importance

of Europe. The continent has the good fortune to lie chiefly in a temperate rather than a torrid zone, and in temperate latitudes to be much nearer to Europe than to Asia. Whatever may have been the first home of the aboriginal inhabitants, the dominating people of to-day are derived from the leading countries of the Old World. Not only so, temperate North America has become the most progressive part of the continent because of receiving its new population chiefly from the most advanced nations of middle western Europe—Great Britain, France and Germany; while the torrid islands and the narrowing southern mainland of North America have been settled chiefly from the less energetic peoples of southern Europe; and the inhospitable northern lands are hardly entered at all by newcomers, except in the recently-discovered gold fields of the far north-west. From the plantation of colonies on the eastern coast, the movement inland has been governed to a remarkable degree by physiographic factors, such as form, climate, and products. The cities of the Atlantic harbours and of the adjacent lowlands still take a leading part in industry and commerce, because of their longer establishment and of their relation to Europe. The uplands, ridges, and mountains of the Appalachian system—the "Backwoods" of a century ago—still remain rather thinly occupied except at certain centres where coal or other earth-product attracts an industrial population. Beyond the Alleghenies, the middle interior contains a very large proportion of habitable land. It was long ago recognized as a land of great promise, and it is to-day a land of great performance, covered with a wonderful network of single-line railways, yielding an enormous product of grain, and developing industries of all kinds towards a future of rapidly increasing power. Indeed, within and closely around an area marked by the St Lawrence system on the north, the Ohio on the south, and stretching from the Atlantic coast between the Gulf of St Lawrence and Chesapeake Bay inland to the middle prairies, there is a remarkable concentration of the population, industry,

progress, wealth, and power of North America—the focus of attention from all other parts of the continent. The regions of the far north and north-east, including the greater part of the Laurentian highland and the extreme northern stretch of the Medial plains and the Western highlands, remain and will long remain thinly populated. The furs of wild animals are their characteristic product. Timber is taken from their more accessible forests; but only in mining districts does the population notably increase, as in the iron region around Lake Superior and in the recently-discovered Klondyke gold region.

In the south-eastern United States lies a belt of coastal lowlands skirting the Appalachians, long blighted by negro slavery and still suffering under its consequences, not only because the institution of slavery demanded the importation of African savages, but even more because its perpetuation held the slaves in ignorant poverty and made labour disgraceful, and still more because its abolition has not yet removed the race prejudice under which the progress of the negro, even only to political equality with the whites, is so long delayed. This is nowhere the case with European immigrants of whatever nationality or religion. The descendants of the early French settlers of Canada stand in political rights as well as in loyalty to the Government on an equal footing with the British citizens of the Dominion. The Italians of the cities, the Hungarians of the mines, the Scandinavians of the northern prairies, the Irish and Germans everywhere are "Americanized" in the second or third generation, rapidly entering local and national politics, and hardly less rapidly attaining an honourable social standing as tested by intermarriage with English and other stocks. But the negro is set aside, even though he has adopted the language and the religion of his former masters: political and social rights are denied him, and intermarriage with whites is practically excluded, although mulattos are numerous. Thus has slavery left upon a people, amongst whom political rights and social opportunities should be equal for all, the heavy burden that has always retarded progress where strongly contrasted races are brought together. Farther south still are the tropical islands and the narrowing mainland, rich in possible productiveness, but slowly developed because of a prevailing diversity and instability of government and lack of progressive spirit among the people. Here also there is a considerable proportion of negroes, but they live under less unhappy conditions than those now obtaining in the United States.

West of the Mississippi in middle latitudes the population rapidly decreases in density, and over a large extent of the semi-arid plains it must long remain sparse. The settlements bordering the plains on the east longitude for a time marked the "Frontier" of civilisation, for the vast stretch of dry country was a serious barrier to farther advance. But the plains are now crossed by many railways leading to the Cordilleran region—the "Far West"—in large part too rugged or too arid for occupation, but rich in minerals from one end to the other, the seat of many mining camps of unstable population, and containing numerous regular settlements in the intermontane basins. On nearing the farther ocean the climatic conditions improve, and the population is rapidly increasing in number and wealth; this district not being content to take its name with respect to the east, not considering itself as included in the "Far West," but choosing the distinctive designation of the "Pacific Slope," and, while maintaining an active intercourse all across the breadth of the continent, already opening relations with the distant Orient by a new approach. Among the earliest results of the latter movement was the arrival of Chinese labourers, a humble,

industrious and orderly class of men, but one which stands apart in language, religion, and race from the dominant population, lives largely without domestic ties, and gains neither political nor social standing in the New World.

Two hundred years ago the aboriginal population of North America would have deserved description before the immigrant population. To-day the aborigines are displaced from all the most valuable parts of the continent. Never very numerous, they are now decreasing; many tribes are already extinct, many more are almost so. Those which remain less diminished are in the Far North or North-West, where nature is rigorous; or in the tropical forests of Central America where nature is overbounteous; or in the more desert parts of the Middle West where nature is arid. The replacement of the native races by the foreign has too often been harsh, cruel, and unjust; yet it has resulted in an advance of civilization. Many savage tribes, speaking many different languages, holding little intercourse with each other, and frequently engaged in intertribal wars, have given place in little more than two centuries to a great population of European origin, whose dominant parts speak one language, whose arts are highly advanced, whose home intercourse is most active, and whose foreign commerce has attained unexpected proportions at the opening of the 20th century.

(W. M. D.)

SOUTH AMERICA.

Granites and gneisses, supposed to be of Archæan age, occur at many places along the east side of the Andes, in the highlands of Venezuela and near the coast about Caracas. There is a more or less continuous area of granites along the watershed between the Amazon and Venezuela and the Guianas extending from the fall line on the Cunani, and the Araguay on the east to the mouth of Rio Meta on the Orinoco, and the mouth of the Uauapés on Rio Negro. In this region the granites are overlapped in many places by more recent beds of unknown age. In the highlands of Brazil south of the Amazon they are found at the falls of the Madeira river, on the Tapajos, at the falls of the Xingú on the south side of the Amazon valley, and along the eastern border of the continent, with certain short interruptions from Maranhão, Brazil, southward to Montevideo, at the mouth of the Rio de la Plata. The largest of these granite areas is the one along the east coast and in the highlands of Eastern Brazil, but even here it is more or less irregular in outline, and its exact limits are unknown except on the immediate coast. Associated with the granites and gneisses is a series of metamorphosed beds exposed over a still larger area. These include schists of various kinds, itacolumites, itabirites, slates, quartzites, and marbles. The series is more or less folded, faulted, veined, and cut by old eruptives. The age of these beds has never been definitely determined, for they have thus far yielded no fossils. In many places they bear a strong resemblance to the Algonkian series of North America, but their position would admit equally well of their reference to the Cambrian. In this series occur most of the mineral deposits of the eastern part of the continent—the gold veins of Venezuela, of the Guiana highlands, and of the gold regions of Brazil, and also the iron, manganese, diamonds, and topazes of Brazil.

Rocks of Silurian age have been found in the Amazon valley, on the north side of the river east of Manaos; in Bolivia, along the eastern slope of the Andes and near Cuyabá, about the headwaters of the Rio Paraguay. It is quite possible, even probable, that many of the unfossiliferous beds, now provisionally referred to the Cambrian, are of Silurian age. The Amazon river along

its lower course, that is, east of Manaos, flows through a Devonian basin filled with rocks of later age. Near longitude 55°-56° W., Devonian rocks outcrop on both sides of the stream a little more than a hundred miles away from it. It is improbable that this Devonian basin extends far up the Amazon valley, for there are metamorphic rocks on the Rio Negro, a short distance above Manaos. In the highlands of Matto Grosso, Brazil, just east of Cuyabá, Devonian rocks cap the hills. Devonian beds are known in Bolivia along the eastern slope of the Andes, and it seems probable that they extend north and south along the range for a long distance. In the state of Paraná, Brazil, a belt supposed to be of Devonian age crosses the state from north to south (Derby), dipping westward beneath a series of rocks referred to the Trias.

The known areas of Carboniferous rocks in South America are small—one basin underlying the Lower Amazon valley contains marine fossils, having a Permian facies. Carboniferous rocks of about the same geological horizon are known also from the vicinity of Lake Titicaca in Bolivia. In the state of São Paulo, and extending into the adjacent states of Minas Geraes and Paraná, is another Carboniferous or possibly Permian basin, but the fossils are scarce and are not marine. The western and southern limits of this São Paulo basin are not known at present. In the southernmost states of Brazil, namely, in Santa Catharina and Rio Grande do Sul, there are at least six separate basins in which coal of Carboniferous age occurs. One of these basins is on Rio Tubarão, near Laguna, Santa Catharina; another is on the Rio Verde, the line between Santa Catharina and Rio Grande do Sul. In Rio Grande do Sul there is one coal basin at Candiota on the railway leading from Pelotas to Bagé, another near the south end of Arroyo dos Ratos, one 100 miles in length lies along the south side of Rio Vacacahy, and another is just west of the city of Porto Alegre. Overlying the rocks of Carboniferous or Permian age in Minas São Paulo and Paraná, Brazil, is a series of sediments and eruptives that have been referred provisionally to the Triassic. Thus far no fossils have been found in them. Rocks believed to be of Triassic age occur in Paraguay, near Diamantino, in the states of Matto Grosso, Brazil, and in Chile and Bolivia. Jurassic rocks are found in Chile, Bolivia, Peru, and the Argentine Republic, and it is possible that some of the Brazilian rocks previously referred to the Triassic belong to the Jurassic.

Rocks of Cretaceous age cover a large area in the interior of the states of Ceará, Piauhý, Parahyba, and Pernambuco in Brazil, while on the coast of the states of Sergipe and Alagôas there are Cretaceous beds containing an abundance of marine fossils. Cretaceous rocks are found in Tierra del Fuego, in Southern Patagonia, in the province of Santa Cruz, Argentine Republic, and they extend northward along the eastern flank of the Andes, with interruptions through Ecuador, Colombia, and Venezuela. On the west side of the Andes a narrow belt of Cretaceous extends nearly or quite the whole length of the continent. The coal or lignite beds of Southern Chile are in the Laramie of the upper Cretaceous. Cretaceous rocks cover a part of the island of Trinidad, off the north coast of Venezuela, and the same Cretaceous basin extends over a part of the Venezuela mainland. The rocks of this age on Trinidad are of organic origin, and it is from these that the remarkable pitch deposits of that island have been derived.

Eocene Tertiary beds occur on the island of Trinidad and on the Venezuela mainland, but it is not known how far these beds extend to the south along the eastern border of the continent. Just south of the Rio Oyapok granites are exposed on the lower courses of the streams,

but on the lower part of the Rio Araguay sedimentary beds form low hills, and extend along both the north and south sides of the Amazon valley for hundreds of miles. These beds have generally been regarded as Tertiary, but they have yielded no fossils, and their age is not known. There are fossiliferous Tertiary beds of brackish water origin in the Upper Amazon valley covering a large area, extending westward from Tabatinga, on the Brazilian frontier. Tertiary beds form a narrow belt along the coast of Brazil, probably from the Amazon valley to near Victoria in the state of Espirito Santo. This belt is a hundred miles wide at some places, while at others it is only a fraction of a mile in width, or is entirely wanting. At and for some miles north of Pernambuco the fossiliferous portions of these beds show them to be of marine origin; south of Pernambuco, on the coast of Alagoas and in the state of Bahia, they are of fresh-water origin. The sandstone reefs of the Brazilian coast, the elevated beaches of Bahia and Rio de Janeiro, and the older parts of the coral reefs, may possibly be of late Tertiary age. Beds known to belong to the Tertiary spread over a wide area in the valley of the Rio de la Plata, and over the lowlands of Eastern Argentina and Patagonia. On the west coast Tertiary rocks form much of the narrow plain between the Andes and the ocean, and there are besides isolated Tertiary basins in the high parts of the mountains.

Some of the eruptive rocks of the Andes are post-Tertiary, while others are pre-Tertiary. The eruptives of the Paraná basin are newer than the Trias, but their age has not as yet been more precisely determined. All through the highlands of Venezuela, the Guianas, and Brazil, the older Palaeozoic rocks are extensively cut by eruptives. Along the north-eastern and south-eastern sides of the continent, most of these eruptives are pre-Tertiary. In only one place—on the Abrolhos Islands—is there a dyke known to be in rock of Tertiary age, while the island of Fernando de Noronha is the only place on the eastern side of the continent at which a volcano of late geologic age is known to have existed.

The earliest land areas of the South American continent are approximately represented by the areas of old granites

and gneisses. The largest of these is along the eastern border of the continent, reaching, with few interruptions, from a short distance south of the mouth of the Amazon river to the mouth of the Rio de la Plata. To the west of this land area there were probably many islands over what is now the interior of the continent. North of the present Amazon valley there was another and smaller land area or islands, where are now the highlands of North-eastern Brazil, South-eastern Venezuela, and Guiana. Another land area, or perhaps more correctly a string of islands, extended from the Falkland Islands the entire length of the west side of the continent. Against these shores the Cambrian or oldest sediments of the continent were laid down.

At the close of Cambrian times elevations of the continent added large tracts to the land, but the Silurian seas still covered what is now the Paraguayan basin, and extended from the Serra do Mar on the Brazilian coast to the axis of the Andes, on the Pacific side of the continent. During the Devonian period the land area of the continent was greatly increased in the Brazilian highlands, but the Devonian seas still covered the interior of the continent, extending from the Serra do Mar on the east to the Andes of Bolivia and Peru on the west, and forming a mediterranean sea over two hundred miles wide and several hundred miles long in the Lower Amazon valley region. In Carboniferous times the Amazonian inland sea

SKETCH MAP OF SOUTH AMERICA.

was only slightly changed, but in the southern part of the continent the land areas increased enormously. In Southern Brazil there were peat bogs, while farther north and west were shallow brackish water bays or estuaries.

But little is known of the Triassic and Jurassic history of the continent.

The Cretaceous history of the east coast is preserved in only a few fragments of sedimentary areas. About the mouth of Rio São Francisco the land sank, carrying beneath the water large portions of the states of Sergipe and Alagoas. What are now the highlands of the interior of Piahy, Ceará, Pernambuco, and Parahyba were then under water. The island of Trinidad was two-thirds under water at that time. On the west coast the land was lower than at present, and the ocean washed the base

of the Andes at many places. Here and there, however, along that coast were great peat marshes extending from Peru as far south as the Strait of Magellan. The sea covered what are now the plains of Patagonia and Argentina, and there was a wide bay between the low Andes ridges on the west and the Uruguayan peninsula on the east.

In the early part of Tertiary times the land sank somewhat, but the geography of much of the eastern coast was not greatly different from its present form. From Santa Catharina to Victoria on the coast of Brazil the shore was very nearly where it now is. From Victoria to Cape St Roque the shore line was from a few miles to a hundred miles farther inland than it is at present. Much of the coast belt, however, was covered by freshwater lakes, and in the Amazon valley region it is possible that these lakes, or some combination of lakes and estuaries, extended far up the valley.

In Tertiary times, probably at the end of the Eocene, great changes took place in the geography of South America. The entire continent rose to an elevation much greater than that at which it now stands. The coast lines were carried oceanward on all sides, so that the continent was enormously larger than it is at present. The coast line was 200 miles to the east of the Abrolhos Islands, which were then a part of the mainland, and 300 miles east of Victoria, Brazil. The Falkland Islands were also a part of the continent, and it is even probable that South America joined New Zealand and Australia through the antarctic regions. Denudation was very active during this period, and enormous quantities of the Eocene sediments were removed from the land. Towards the close of Tertiary times the continent sank again until the sea entered the Orinoco and Amazon valleys and made an island or group of islands of the highlands between Brazil, Venezuela, and the Guianas. During this period the valleys of Magdalena and Canca and of Lake Maracaibo were covered by great bays. Still later a slight elevation added to the continental land area the lower portions of the Orinoco, Amazon, and La Plata valleys. During the Tertiary period volcanic activity culminated on the continent. The Andes rose, partly by continental uplifting, partly by faulting and folding, and partly by an upbuilding by the volcanic ejectamenta, from a series of comparatively low ridges to be the great mountain chain of the world. Volcanic activity, which had previously characterized the west coast region, increased enormously, lava sheets were poured out along the entire length of the continent, and enormous lava and cinder cones were built up about the craters. This volcanism was not confined to the Andes, but extended to the Patagonian plains, the highlands of the Paraná basin, the Abrolhos Islands, and as far east as the island of Fernando de Noronha. In recent times volcanic activity has entirely ceased along the eastern and north-eastern parts of the continent, and it has also subsided greatly, though it has not ceased altogether, along the west coast. The earthquakes that still disturb the west and north-west coast of the continent are more or less the result of this diminished volcanic action.

During Pleistocene times the southern end of the continent as far north as latitude 27° on the west coast was covered with glaciers moving away from the mountain ranges. North of 27° the glaciers did not flow down as far as the present sea-level, but they moved farther down the slopes of the higher portions of the Andes than they do at present. During a portion of the Glacial epoch the southern end of the continent stood at a somewhat lower elevation than at present, and the sea covered the plains of Patagonia and La Plata. On the east coast

evidences of glaciation do not extend as far north as they do on the west coast.

The South American continent rises abruptly from the ocean's floor along nearly all its coast line, but the abruptness of the continental margin is more marked on the western than on the eastern side. Contours of equal depth along the west coast show that from Valparaiso to the Isthmus of Panama, a distance

Physical
geography.

of 3000 miles, the great Andes ranges are but the upper or subaerial portions of mountains rising from bases that lie 10,000 feet below the surface of the Pacific Ocean. South of Valparaiso the 10,000-foot contour moves far off the coast, but opposite the Strait of Magellan it approaches again within a distance of 150 miles. East of Patagonia the 1000-foot contour is so far from the coast that it passes to the east of the Falkland Islands, showing that this group stands upon a submerged continental shelf. From the mouth of the Rio de la Plata northward the 1000-foot submarine contour keeps at a

EASTERN BRAZIL.

distance of from 50 to 150 miles off the shore, nearly to Bahia, Brazil; from Bahia northward clear around Cape St Roque this line is close to the shore, and the ocean's bottom is steep, dropping abruptly to a depth of 5000 feet. The land relief of the continent of South America is characterized by—(1) the great range of lofty mountains which, with its narrow coast plain, follows its west coast from its northern to its southern extremity; (2) comparatively low and flat plains that slope eastward and southward from the base of these mountains down the drainage basins of the Orinoco, the Amazon, and the Paraguay; (3) the high table-lands of Eastern Brazil. The physical features of the west coast are bold. South of latitude 41° , the coast is characterized by a vast system of fjords and islands, probably produced by the recent submergence of a region of bold mountains and steep-sided valleys. The many islands, including Chiloe, Wellington, and Tierra del Fuego, are the higher portions that have remained above water; while the Strait of Magellan (properly Magalhães), Smyth Channel, and the other deep fjords that indent this coast line are the submerged valleys. The scenery in Smyth Channel is remarkably fine; the snow-clad mountains are visible on the east, while here and there glaciers flow down nearly or quite to the sea. Some of the islands are steep-sided peaks, mostly barren and uninhabited, and, in some cases, reaching an elevation of 4000 feet. The Strait of Magellan is 400 miles long, from 4 to 20 miles wide, and very deep. North of latitude 41° the coast is but little indented, and there are but few good ports. From Cape Horn, where the southern submerged end of the Andes forms the islands of Tierra del Fuego to the Isthmus of Panama, the great Cordillera range follows the coast line closely, and at an even distance from it. The belt between the ocean and the mountains has an average width of about 40 miles, and on rare occasions, when the weather is favourable, the mountains are visible from the sea nearly all the way from Panama to the Strait of Magellan. Along the northern part of the continent, from Panama to Guayaquil,

the coastal belt is covered with tropical vegetation; but from Guayaquil southward to latitude 30° much of the coast is a sandy, arid, and barren alkali desert. This arid belt is crossed here and there by streams flowing down from the high mountains, and along these streams are fertile valleys. Many of the streams, however, do not reach the sea, but dry up on their way across the coastal plain.

The great mountain chain is neither a single continuous sharp range nor a pair of ranges, but a broad ridge upon which rise many great isolated peaks. Towards its northern end, however, this great range divides—one branch, the Western Cordillera, continuing northward along and near the coast; another, the Merida, swinging away to the east, and, after certain

PEAKS OF THE ANDES.

breaks, ending east of Caracas in Venezuela, or, more properly, on the northern side of the island of Trinidad; while a third branch, the Sierra de Perija, runs northward between the valley of the Magdalena and Lake Maracaibo. On its west side the main Cordilleran ridge is scored by narrow steep-sided valleys, while on its eastern slope the average grade is more gentle and the valleys are less precipitous. Upon the Cordilleran ridge rise many of the highest mountain peaks in the world. The following are some of the highest and most noted of these peaks:—

Peak.	Elevation.	Snow-line (approximate).
Aconcagua, Argentina . . .	23,080	17,500
Mercedario, Argentina . . .	22,315	...
Tupungato, Argentina . . .	21,550	...
Illampu (Sorata), Bolivia . . .	21,500	...
Illimani, Bolivia . . .	21,030	...
Sajama, Bolivia . . .	21,028	...
Chimborazo, Ecuador . . .	20,545	16,700
Juncal, Chile . . .	20,180	...
San Jose, Chile . . .	20,020	...
Cotopaxi, Ecuador . . .	19,813	15,500
Antisana, Ecuador . . .	19,335	16,000
Cayambé, Ecuador . . .	19,186	15,000
Tacora, Bolivia . . .	19,000	...
Tolima, Colombia . . .	18,300	...
Misti, Peru . . .	17,934	...
Altar, Ecuador . . .	17,730	14,000
Maipó, Argentina . . .	17,670	...
Sangai, Ecuador . . .	17,464	...
Illiniza . . .	17,405	...
Torlola, Argentina . . .	17,350	...
Carihuairazo . . .	16,750	15,000
Tunguragua, Ecuador . . .	16,690	...
Sierra de Santa Marta, Colombia . . .	16,640	...
Sincholagua . . .	16,365	15,300
Cotacachi, Ecuador . . .	16,301	14,500
Pichincha Ecuador . . .	15,918	...
Sara-urca . . .	15,502	14,000

There are several other peaks whose elevations exceed some of those given, but they have never been measured. The elevation of the snow-line upon these mountains varies somewhat, but it is lower on the east than on the west side. Of these peaks Cotopaxi, Tunguragua, Maipó, and Sangai are the largest active volcanoes in the world.

There are glaciers in the Andes immediately beneath the equator. The largest of these are upon Antisana, Cayambé, and Chimborazo, Altar, Carihuairazo, Cotacachi, Illiniza, Sara-urca, and Sincholagua (Whymper). Farther south in Chile and Argentina there are glaciers upon Aconcagua, Tupungato, &c., while in Patagonia along Smyth Channel and in the Strait of Magellan they are very large and flow down to the sea. The high Andes regions, even far below the lofty peaks, are cold, bare of vegetation, monotonous, and desolate. At a very few

places there are cities and towns in the high mountains; Quito in Ecuador has an elevation of 9343 feet, Bogotá in Colombia of 8665 feet, while La Paz in Bolivia is 12,000 feet above the sea. The highest habitable portion generally has an elevation of about 8000 feet. But for the most part the lofty regions are unpeopled, so much so that this belt is known as the *Despoblado* or the unpeopled country. The high barren belt is comparatively narrow in Peru, but it widens southward through Bolivia, Chile, and Argentina. It has an average width of about 150 miles. (For further details see ANDES.)

The mountainous character of the western side of the continent ends abruptly in the Strait of Magellan. Northward along the east side of the continent the coast is flat as far as the northern part of Rio Grande do Sul. From latitude 33° 30' to latitude 29° 30' the coast is bordered by large brackish lakes. At latitude 29° 30' the coast mountains of Brazil (the Serra do Mar) are near the ocean and follow the shore northward as far as latitude 19° 30'. This piece from 29° 30' to 19° 30' is the most picturesque portion of the Brazilian coast. The mountains rise in many places directly from the seashore to an elevation of more than 2000 feet. Where their sides are not smooth bare granite, they are covered with luxuriant tropical vegetation from base to summit. The port of Rio de Janeiro, one of the most beautiful in the world, and the ports of Santos and Victoria as well, are formed by a late depression of the coast that admitted the sea to narrow submerged valleys that had been cut by denudation on the margins of granite mountains. From latitude 20° northward the mountains swing inland, and the coast is low as far as Prado, latitude 17° 25'. North of Prado the coast is bordered by a wall of brightly coloured bluffs from 50 to 250 feet high, which continue with interruptions almost to the mouth of the Amazon. About Cape St Roque the coast is covered with sand dunes. From the Abrolhos Islands (lat. 18°) northward to Cape St Roque there are many coral reefs. In some places these reefs are several miles off shore, as they are near the Abrolhos, and many miles in length and breadth; in other places they follow the coast line for a hundred miles or more with few interruptions, now touching the shore and now standing out two or three miles from land. Occasionally there are small ports behind them. The most considerable break in their continuity is between the Bay of Bahia and the mouth of the Rio São Francisco. Along this same coast are reefs of hard sandstone that are often mistaken for coral reefs. These stone reefs stand like artificial walls or breakwaters across the mouths of the smaller rivers and the choked-up valleys, and thus form several of the ports on this part of the coast; such are Pernambuco, Natal, Porto Seguro, and several others of minor importance.

The Serra do Mar, or Brazilian coast range, is the most prominent topographic feature of the eastern side of the continent. This range, or group of ranges, backed by a high plateau, is within sight of the ocean from the north-eastern corner of Rio Grande do Sul in Brazil (lat. 29° 30') to the mouth of Rio Doce, in S. latitude 19° 30'. The following are the highest points that have been measured on the Brazilian highlands:—

Peak.	Elevation.
Itatiaya, State of Rio de Janeiro . . .	9840 feet
Itajubá or Tembé, State of São Paulo . . .	7800 ± "
Organ Mountains, State of Rio de Janeiro . . .	7323 "
Frade, State of Espirito Santo . . .	6770 "
Caraga, State of Minas Geraes . . .	6234 ± "
Itambé, State of Minas Geraes . . .	5900 ± "
Itacolomi, State of Minas Geraes . . .	5748 "
Morro do Lopo, State of São Paulo . . .	5250 "
Serra da Onça, State of Rio de Janeiro . . .	4592 "
Pyreneos, State of Goyaz . . .	4544 "

There is an elevated region near the eastern corner of the continent on the watershed between Rio São Francisco, Rio Jaguaribe, and Rio Parahyba do Norte. This watershed is not a mountain range, but a broad and broken plateau with an elevation of about 3000 feet, and with individual peaks reaching 4000 feet above tide level.

North of the mouth of the Amazon the coast is low, much of it is swampy, and all of it is forest-covered as seen from the ocean. This low coast extends across the Guianas and Venezuela as far as the headland north of the Gulf of Paria, where the Merida or Venezuelan branch of the Andes reaches the sea. Along this Guiana coast is a belt of low wooded land, beyond which the streams are not navigable save by canoes. The highlands south of Venezuela and the Guianas, and north of the Amazon valley, form a broad plateau, above which rise several high peaks. The known peaks are:—

Roraima	8740 feet.
Ouida	8500 "
Maraguaca	8230 "
Turagua	6000 "

This highland is mostly forest-covered, but there are in the area also large campos or open grass-covered plains.

The Amazon, the Orinoco, and the Paraguay or La Plata river systems drain an area of 3,686,400 square miles. Less imposing, but yet large and important streams are the Magdalena in Colombia,

Rivers. the Essequibo in British Guiana, and the São Francisco in Brazil. The Amazon (properly the Rio das Amazonas or river of the Amazons) and its tributaries is not only the largest river in South America, but by far the largest in the world (*q.v.*). The total navigable length of the main stream, from Pará to the head of the navigation on the Huallaga in Peru, is 3000 miles. This does not include the hundreds of equally navigable parallel side channels that accompany the main stream from its mouth almost to the mouth of the Javary. Above the falls, again, all these streams are navigable for long distances. The river is nowhere confined to a single channel, but its waters spread over an enormous flood-plain and flow with a sluggish current through thousands of side channels that anastomose with each other so that it is impossible for one not familiar with the stream to distinguish the main channel. In several places the river is so wide that one looking across it sees a water horizon as if he were looking out over the ocean. Indeed much of the region is more like a great freshwater sea filled with islands than it is like a valley with a stream running through it. For the most part the land along the river is low, flat, and marshy, and under water a part of the time; but at a few places, notably at Ereré, Obidos, Velha Pobre, Pará Paraná-quára, and Almeirim table-topped hills are visible from the river. The banks of the stream and of its side channels are everywhere lined with a dense forest. The valley, however, is not all forest-covered. Beginning near the Oyapok on the Guiana frontier, a series of dry sandy campos or open grassy plains, interrupted by wooded river banks, follow along the north side of the river for about 700 miles. The Upper Amazon valley opens broadly towards the north-east and descends to the sea through the Orinoco, while towards the south the Madeira basin, through one of its upper branches—the Guaporé—unites with the basin of the Paraguay.

The Orinoco proper (*q.v.*) rises in the highlands between Brazil and Venezuela, by a broad curve swings around the western end of these highlands, and then for 400 miles flows east into the Atlantic. Along its lower course the banks are covered with heavy forests. In its upper course the mountainous highlands are visible along its right bank, while on its left are enormous stretches of flat, tree-

less, grass-covered plains, extending to the foot-hills of the Cordillera de Merida. During high water, the low, flat country looks like a vast lake. The stream is navigable during a part of the year a distance of 1000 miles or more. Unlike the Amazon, the Orinoco has a great delta, and the stream enters the sea through many channels.

Under the name of the Rio de la Plata (*q.v.*) may be included the Uruguay, the Paraná, and the Paraguay, with all their tributaries. The plains of Argentina begin on the Amazonian watershed in the highlands of Matto Grosso, Brazil, and in Eastern Bolivia, and following down the valley of the Paraguay pass out of the drainage area of the Paraná, properly speaking, and form the flat region lying between the foot-hills of the Andes and the Atlantic Ocean almost to the Strait of Magellan—a length for this plain of more than 2000 miles. The plains in the latitude of Buenos Ayres and from there southward are low, nearly flat on the east side, and rise almost imperceptibly to the lower slopes of the Andes. They are mostly treeless deserts covered with tufts of coarse grass, with here and there shallow pools of salt or brackish water. There are many small volcanic peaks and some short mountain ranges over this great plain.

The valley of the Paraguay is here and there heavily timbered, in other places it is a treeless or sparsely-covered grassy plain, and in still others it is a hilly, dry, and thinly-covered campo. The upper Paraguay river winds through grass-covered, meadow-like plains apparently as flat and boundless as the sea. Above this plain rise a few isolated peaks, like so many islands in a great lake. Only above the navigable portions of the stream, 1700 miles from its mouth, does it flow through a hilly country. A noteworthy feature of the tributaries of the Paraguay is that many of those flowing down from the region of the Andes are more or less brackish, while the Uruguay and Paraná and their tributaries entering from the rainy, forest-covered regions of Brazil, are all freshwater streams.

The São Francisco is the largest river that lies wholly in Brazil. It rises in the highlands not far from the coast in latitude 21° and flows north-east parallel with the coast until it reaches latitude 9° 30', where it bends sharply to the right and enters the Atlantic 360 miles south of Cape St Roque. It is navigable in its lower course, but at a distance of 140 miles from its mouth the falls of Paulo Affonso, the "Niagara of Brazil," interrupt all navigation. The upper part of the river, however, is navigable for a long distance. Throughout its entire length it flows through a hilly or mountainous country.

The Rio Magdalena in Colombia is a crooked, muddy stream entering the sea through two mouths; it is navigable up to Honda (862 feet above tide-level) and has a length of 2000 miles. Above the mouth of Rio Cauca, the mountains are visible on both sides of the river.

There are remarkably few freshwater lakes in South America, and most of these are in the Andes mountains. Lake Titicaca, near La Paz in Bolivia, is, in respect of elevation and position, the most remarkable lake of its size in the world. Its surface has an elevation of 12,545 feet, it covers an area of between 4000 and 5000 square miles, has a maximum depth of 700 feet, and never freezes over. Titicaca discharges into another shallow lake or marsh which is supposed to have no outlet. Lake Junin or Chinchicocha on the plateau east of Lima in Peru has an area of 200 square miles, and an altitude of 13,380 feet. Along the eastern base of the Andes, in Southern Argentina, is a series of lakes whose basins were probably formed by the glaciers that formerly flowed down to the plains from the mountain ranges. There are many lakes over the

Lakes.

flood-plains of all the great rivers of South America, but these are phases of the rivers themselves rather than lakes in the ordinary sense. Lagoa dos Patos and Lagoa Merim on the southern coast of Brazil are shallow brackish lakes shut in by sandbanks thrown up by the sea. There are small lagoons, formed in a similar manner, at many places along the coast in the states of Rio de Janeiro, Espirito Santo, and Alagôas. Lake Maracaibo on the Venezuela coast is a narrow-necked bay rather than a lake.

The eastern coast of the South American continent has remarkably few islands, and these are all small, except *islands.* Trinidad, off the coast of Venezuela, and the islands in the mouth of the river Amazon.

The island of Trinidad (area, 1755 square miles) is separated from the continent by the Gulf of Paria. Along the northern end of the island is a range of mountains about 3000 feet high, which are geologically the eastern end of the Cumana range of the Venezuela mainland, with which they were formerly united. On the south side of the island is the famous pitch lake—the most extensive deposit of asphalt known. The island of Fernando de Noronha, 230 miles off Cape St Roque, is of volcanic origin, and has an area of 12 square miles. Although this island is separated from the mainland by a channel 13,000 feet deep, it really stands on the deep continental shelf. The Rocas, a small coral island, lies 80 miles west of Fernando de Noronha. The shores of the Falkland Islands (area, 6500 square miles) are indented by long tortuous channels that have the appearance of having been formed by the depression of a hilly land surface. One of these channels quite separates the two main islands. One peak, Mount Adams, has an elevation of 2300 feet. The group is separated from the mainland by a shallow sea, while its flora and fauna show that it was formerly connected with the Patagonian mainland. The Tierra del Fuego group of islands and the other islands that border the south-west coast, from the Strait of Magellan to latitude 42°, by their flora, fauna, the land forms and the forms and depths of the channels about them, show that they were not long ago, geologically speaking, a part of the mainland, from which they have become separated by the depression of the southern portion of the continent. This depression has admitted the sea to the lower valleys, making fjords of them, while the highlands and mountain tops remain projecting from the water as islands.¹

The flora of South America embraces a large number of peculiar types originating either in the highlands of

Brazil or in the Andes region. Several of our *Flora.* most useful plants are natives of the South American tropics. Among these are the rubber-producing plants, cotton, potatoes, maize, the cinchona, Paraguayan tea, ipecac, vegetable ivory, coca, and the chocolate plant. Other tropical and subtropical plants, such as coffee, sugar-cane, oranges, and bananas have been introduced, and are extensively cultivated. The flora of the Amazon valley may be taken as the type of that of the moist valleys. The forests are almost impenetrable; roads through them are soon closed by the rank growth, and vines, creepers, and climbing plants turn them into veritable mats down to the water's edge. Bamboos reach an enormous size and form extensive thickets along certain streams. Palms are the most characteristic and beautiful trees, and reach their greatest development in the Amazon

valley. They take on a great variety of forms: some have a height of 100 feet or more, others are no larger than a lead pencil and only a yard high; some are trunkless, while others are slender and climb like vines. A noteworthy feature of these tropical plants is that they seldom form forests of a single or of a few species, as so often occurs in the temperate zones. The shaded woods of the forests in many places abound in beautiful ferns, some of them reaching the dimensions of trees. The plants of the campos and plains have a stunted appearance. The grasses are wiry and tough, in places spreading evenly over thousands of square miles of nearly level marshy lands, as in the Gran Chaco of the Paraguay valley, in others growing in tufts over the sandy plains. In the high table-lands of Southern Brazil, the araucarian pine grows in beautiful forests as far north as Barbacena, state of Minas. In the north-west, the western slopes of the mountains are covered with a dense tropical vegetation high up their sides, while on the east they are comparatively bare. In the high mountains, the flora, though scant, resembles that of temperate regions. Sixty per cent. of the genera are like those of the temperate zones, but the species are peculiar to the Andes. On the lofty peaks Whymper collected, of flowering plants, fifty-nine species above 14,000 feet; thirty-five species above 15,000 feet; and twenty species above 16,000 feet.

The fauna of South America includes a large number of species, but relatively a small number of individuals.

With local exceptions, this seems to be true of *Fauna.* all the forms of life. The land mammals are nearly all small. There are many species of monkeys, all of them arboreal. The only reptiles that are at all abundant are lizards, and, in some places, alligators. There are only two large snakes, the boa constrictor and the water boa, and they are not abundant. The other kinds of snakes are represented by a small number of individuals. Certain ruminants having long woolly hair, the llamas, alpacas, and vicuñas, are found only in the high Andes. The llama has been domesticated, and is used for carrying small burdens. The condor, the largest living bird of flight, inhabits the lofty Andes. The insects of the highest peaks are related generically, but not specifically, to those of the temperate latitudes of North America, a fact interpreted by biologists to mean that, probably on account of some obstacles to free movement since the Glacial epoch, there has been no migration along the Andes during the existence of living species.

(J. C. BR.)

South American Meteorology.

South America lies between the mean annual isotherms of 40° and 80° Fahr. The northern and north-eastern portions of the continent, down nearly to the *Climate.* tropic, are within the district enclosed by the mean annual isotherm of 80°. The cold Peruvian current deflects the isotherms strongly equatorwards along the Pacific coast, especially between latitudes 30° S. and the equator, while these same isotherms loop strongly polewards over the land. The equatorward deflexion on the west coast results in giving places on that coast much lower temperatures than those of stations in corresponding, or even considerably higher, latitudes on the east coast. Lima, in latitude 12° S., has a mean annual temperature of 66.2°; Rio de Janeiro, which is nearly on the tropic on the east coast, has a mean annual of 72.1°. The mean annual temperatures on the Atlantic coast between latitudes 30° and 40° S. are about 5° higher than those in corresponding latitudes on the Pacific coast. The average position of the heat equator (axis of the equatorial belt of high temperature) is on the immediate sea-coast in North-

¹ The continent of South America has nearly all been explored after a fashion, but much of it has never been mapped. The statements frequently met with to the effect that there are large unexplored tracts should be taken with allowances. The various governments have concerned themselves but little with explorations and mapping, and whatever has been accomplished has been done incidentally rather than for the direct purpose of determining the geography and topography.

eastern Brazil, whence the line runs north-west parallel with, but somewhat inland from, the coast of Guiana and Venezuela. In January the heat equator moves to about 15° S. in Brazil, while in July it migrates northward beyond the limits of the continent. In the former month the isotherm of 50° crosses the southernmost extremity of South America. In July the isotherm of 30° is found somewhat to the south of Cape Horn. Thus the southern

DISTRIBUTION OF HEAT.

summer is not marked by excessively high mean temperatures, and the southern winter is moderate, even in the higher latitudes. The mean annual range of temperature is very small over all of South America. Over the northern portion of the continent, including Peru, Northern Bolivia, and the greater part of Brazil, it is less than 10°. Over a considerable part of this same area the range is even less than 5°. South of the tropic and east of the Andes the ranges increase to between 30° and 40° in Northern Argentina. In Chile, on the other hand, they are less than 20°. The whole of the narrow western coastal strip thus has a very moderate climate. Even in the higher latitudes the winters are very mild; the summers distinctly cool. Over a portion of the coasts of Guiana and of Eastern Venezuela the mean minimum temperatures average over 68°. The lowest mean minima are found in the interior east of the Andes and south of latitude 20° S. Temperatures below 32° occur normally every winter over the highlands of the southern interior of Brazil, and thence southward over the interior of Argentina. The highest mean maxima (104°) occur in the northern portion of Argentina. All of the west coast has decidedly lower maxima. Throughout the mountainous region of South America altitude controls temperature to a marked degree. Places situated far above sea-level (e.g., Quito) enjoy "perpetual spring" temperatures. On the high peaks, even on the equator, there is eternal snow.

For the mean of the year the barometric equator crosses South America closely along the line of the geographical equator, running north of it on the western coast. The middle portion of the continent is under the control of the tropical high pressure belt, while over the southern extremity the pressure decreases rapidly towards the south pole. The seasonal migration of sun and heat equator involve a sympathetic migration of barometric equator and tropical high pressure belt. In January the barometric equator moves south to about lat. 10° in Brazil, while the axis of the tropical high pressure belt lies about along 30° S. lat. in the Atlantic, and 35° S. lat. in the Pacific. In July the barometric equator lies along the northern coast, and the axis of the tropical high pressure belt is also farther north than in January. Seasonal changes and mean monthly ranges of pressure are slight. The broad northern portion of the continent east of the Andes, and north of the tropical high pressure belt, is in the trade-wind zone. Here the trades prevail as a rule, except when the sun is most nearly overhead. They are then replaced by the equatorial belt of calms and rains, which migrates north and south over this portion of the continent, following the sun. The west coast within the trade-wind latitudes south of the equator has its own system of winds, which

are under control of the tropical high pressure area of the Pacific, and blow from a southerly direction. The winds of extra-tropical South America are also chiefly controlled by the tropical anti-cyclonic areas of the South Atlantic and South Pacific oceans. The former of these areas gives easterly and south-easterly winds in the lower latitudes of the eastern portion of the continent, and prevailing north-westerly winds in the higher latitudes. On the west coast strong southerly winds blow with trade-like regularity north of the Pacific anti-cyclone, while north-westerly winds prevail to the south of it. The seasonal migration of these areas of high pressure involves a corresponding shift in the wind systems under their control. In summer south and south-west winds prevail along the west coast between 30° and 40° S. lat. South of 40° S. lat. north and north-west winds predominate. In winter the winds between 30° and 40° S. lat. are variable, with some calms, while the west and north-west winds blow nearer the equator than in summer. In corresponding latitudes on the east coast there is also a northward extension of the limits of the north-west winds in winter. In Argentina north-east, east, and south-east winds increase in summer, and north, north-west, and west winds in winter. In the mountains there are local winds, much influenced by topography.

WIND PRESSURE.

Darwin first distinctly emphasized the essential characteristics of South American rainfall. In the latitudes of prevailing easterly winds (trades) the eastern side of the continent and the eastern slopes of the Andes are well watered, while the western slopes are comparatively dry. In the latitudes of prevailing westerly winds the western slopes of the mountains have the most precipitation, while the eastern side is dry. The rainfall is considerable (60-80 inches and over) on the elevated windward coasts of the continent (Guiana, South-east Brazil) within the trade-wind belts, as it is on the eastern slopes of the Andes, and over an extended area along the Amazon. Within the south-east trade belt there is notably less rainfall in the lee of the highlands of South-east Brazil, and the rainfall also decreases rapidly in the interior over the more southern latitudes of this same belt. The migration of the belt of equatorial calms and rains over the northern portion of

RAINFALL.

South America involves a seasonal rainfall over the greater part of the trade-wind latitudes. There is a dry season while the trade blows, and a rainy season while the equatorial rainy belt is overhead. The coast of Guiana, and Pernambuco and Bahia have winter rains. The west coast within the trade-wind latitudes, from 4° S. lat. to about 30° S., is very dry. It is shut off from the trades, and has southerly, cool, non-rainy winds. Along

this desert coastal strip it seldom rains, but rain and snow fall on the mountains of Peru and Bolivia during the summer. North of lat. 4° S. there is abundant rainfall from the equatorial rainy belt, reaching 160 inches a year on the coast of Colombia north of the equator. Near the west coast the migration of the equatorial rain belt produces two rainy and two dry seasons at certain stations nearly on the equator (Quito and Bogotá). Within the latitudes of the prevailing westerly winds, the rainfall reaches 80 inches annually along the southern coast of Chile. East of the Andes, over much of the pampas of Argentina and Patagonia, the average is under 10 inches. Towards the southern extremity of the continent the rainfall east of the mountains increases again, reaching 40 inches a year in the extreme southeast. There is a seasonal distribution of rainfall in Chile which depends upon the migration of the tropical high pressure belt. Northern Chile, north of about 30° S. lat., is always dry. Southern Chile has rain throughout the year, because it is always under the régime of the prevailing westerly winds. In the central portion there are rains only in winter, when the westerlies impinge on that coast. Cyclonic storms do not occur north of the latitudes occupied by the prevailing westerly winds, but are very common in the high southern latitudes. The winter rains of Central Chile come in connexion with the cyclonic storms of that season. Thunderstorms are most frequent over the north-west coast, as far south as 4° S. lat., and occur in considerable numbers over all of tropical South America, except the arid west coast. The violent summer thunderstorms of Argentina and Uruguay (pamperos) often do serious damage to shipping in the Río de la Plata estuary.

South America may be divided into six climatic provinces (following Supan). The first ("Tropical Cordilleran") includes the extreme north-western section (coasts of Colombia and Ecuador), with "perpetual spring" climates at high altitudes, high temperatures near sea-level, and tropical rains. The second ("Tropical") takes in the vast northern and north-eastern territory east of the Andes, and reaches somewhat south of the tropics. This is under the control of trades and equatorial rains, and has mean annual temperatures over 80°. The third ("Peruvian") extends along the Pacific coast to 30° S. lat., including Northern Chile. This province is abnormally cool, and rainless. The "North Chilean" province, adjoining it on the south, has a sub-tropical climate, with winter rains. Farther south the "South Chilean" province, which takes in also the extreme southern extremity of the continent, is very rainy and has equable temperatures throughout the year,

CLIMATIC PROVINCES.

with cool summers. The sixth ("Pampa") province, which includes the section east of the Andes and south of the tropical province, has a fairly large range of temperature, especially in the north, while rain is not plentiful.

The following brief list includes some of the last notable additions to our knowledge of the geography of South America:—

AMERICAN ETHNOLOGY AND ARCHAEOLOGY.

The opinion is now well-nigh universal among anthropologists that the American aborigines came from the Old World. Whether with Payne it is assumed that in some remote time a speechless anthropoid passed over a land bridge, now the Bering Sea, which then sank behind him; or with Dawkins and Brinton, that the French cave man came hither by way of Iceland; or with Keane, that two sub-varieties, the long-headed Eskimo-Botocudo type and the Mexican round-headed type, prior to all cultural developments, reached the New World, one by Iceland, the other by Bering Sea; or that Malayoid wanderers were stranded on the coast of South America; or that no breach of continuity has occurred since first the march of tribes began this way—ethnologists agree that the aborigines of the western came from the eastern hemisphere, and there is lacking any biological evidence of Caucasoid or Negroid blood flowing in the veins of Americans before the invasions of historic times. The time question is one of geology.

The American aborigines.

Following *Notes and Queries on Anthropology*, published by the British Association for the Advancement of Science, the study of the American aborigines divides itself into two parts: that relating to their biology, and that relating to their culture. In the four subdivisions of humanity based on the hair, the Americans are straight-haired or Mongoloid. But it will free this account of them from embarrassments if they be looked upon as a distinct subspecies of *Homo sapiens*. Occupying 135 degrees of latitude, living on the shores of frozen or of tropical waters; at altitudes varying from sea-level to several thousands of feet; in forests, grassy prairies, or deserts; here starved, there in plenty; with a night here of six months' duration, there twelve hours long; here among health-giving winds, and there cursed with malaria; this brown man became, in different culture provinces, brunette or black, tall or short, long-headed or short-headed, and developed on his own hemisphere variations from an average type.

Since the tribes practised far more in-breeding than out-breeding, the tendency was toward forming not only verbal linguistic groups, but biological varieties; the weaker the tribe, the fewer the captures, the greater the isolation, and harder the conditions—producing dolichocephaly, dwarfism, and other retrogressive characteristics. The student will find differences among anthropologists in the interpretation of these marks—some averring that comparative anatomy is worthless as a means of subdividing the American subspecies, others that biological variations point to different Old World origins, a third class believing these structural variations to be of the soil. The high cheek-bone and the hawk's-bill nose are universally distributed in the two Americas; so also are proportions between parts of the body, and the frequency

of certain abnormalities of the skull, the hyoid bone, the humerus, and the tibia. Viability, by which are meant fecundity, longevity, and vigour, was low in average. The death-rate was high, through lack of proper weaning foods, and hard life. The readiness with which the American Indian succumbed to disease is well known. For these reasons there was not, outside of southern Mexico, northern Central America, and Peru, a dense population. In the whole hemisphere there were not over ten million souls.

The materials for studying the American man zoologically exist in the form of collections in Peabody Museum, Cambridge, Massachusetts, the Academy of Natural Sciences in Philadelphia, and the United States National Museum in Washington. Professor Putnam measured for the World's Columbian Exposition 17,000 living Indians, and the results have been summed up by Boas. The breadth of the Indian face is one centimetre more than that of the whites, and the half-breeds are nearer the Indian standard; this last is true also of colour in the skin, eyes, and hair. In stature, the tall tribes exceed 170 cm.; middle stature ranges between 166 and 170; and short tribes are under 166 cm. The Indians are on the whole a tall people. Tribes that have changed residence have changed stature. The tallest statures are on the plains. The mountains of the south-east and of the west reveal the shortest statures. The whole Mississippi Valley was occupied by tall peoples. The Athapascans of New Mexico are of middle stature, the Pueblo peoples are short. The Shoshone, Shahaptin, and Salish tribes are of middle stature; on the coast of British Columbia, Puget Sound, in Oregon, and Northern California, are the shortest of all the North Americans save the Eskimo, while among them, on the Columbia, are taller tribes. The comparison of cranial indexes is rendered difficult by intentional flattening of the forehead and undesigned flattening of the occiput by the hard cradle-board. The Mississippi Valley tribes are nearly brachycephalic; the index increases around the Great Lakes, and lessens farther east. The eastern Eskimo are dolichocephalic, the western are less so, and the Aleuts brachycephalic. On the North Pacific coast, and in spots down to the Rio Grande, are short heads, but scattered among these are long heads, frequent in Southern California, but seen northward to Oregon, as well as in Sonora and some Rio Grande pueblos. In the regions of greatest linguistic mixture is the greatest heterogeneity of cephalic index.

The concepts on which the peoples of the Old World have been classified, such as stature, colour, skeletal measurements, nationality, and so on, cannot as yet be used in America with success. The only basis of division practicable is language, which must be kept separate in the mind from the others. However, before the conquest, in no other part of the globe did language tally so nearly with kinship. Marriage was exogamic among clans in a tribe, but practically, though not wholly, endogamic as between tribes, wife and slave capture being common in places. In his family tree of *Homo Americanus* Keane follows out such a plan, placing the chief linguistic family names on the main limbs, North American on one side, and South American on the other. Deniker groups mankind into twenty-nine races and sub-races. Americans are numbered thus:—21, South American sub-race; Palæo-Americans and South Americans. 22, North American sub-race; tall, mesocephalic. 23, Central American race; short; brachycephalic. 24, Patagonian race; tall, brachycephalic. 25, Eskimo race; short, dolichocephalic.

Zoologists divide the earth into biological areas or regions, so both archæologists and ethnologists may find

it convenient to have in mind some such scheme of provinces as the following, named partly after the dominant ethnic groups:—Eskimo, on Arctic shores; Déné, in North-western Canada; Algonkin-Iroquois, in Canada and Eastern United States; Sioux, plains of the west; Muskogee, Gulf States; Tlinkit-Haida, North Pacific coast; Salish-Chinook, Fraser-Columbia coasts and basins; Shoshone, interior basin; California-Oregon, mixed tribes; Pueblo province, South-western United States and Northern Mexico; Nahuatla-Maya, Southern Mexico and Central America; Chibcha-Kechua, the Cordilleras of South America; Carib-Arawak, about Caribbean Sea; Tupi-Guarani, Amazon drainage; Araucanian, Pampas; Patagonian, peninsula; Fuegian, Magellan Strait. It is necessary to use geographical terms in the case of California and the North Pacific, the Caucasus or *cloaca gentium* of the western hemisphere, where were pocketed forty out of one hundred or more families of native tribes. The same is true in a limited sense of Matto Grosso. That these areas had deep significance for the native races is shown by the results, both in biology and culture. The presence or absence of useful minerals, plants, and animals rendered some congenial, others unfriendly; some areas were the patrons of virile occupations, others of feminine pursuits.

Among the languages of America great differences exist in the sounds used. A collection of all the phonetic elements exhausts the standard alphabets and calls for new letters. A comparison of one family with another shows also that some are vocalic and soft, others wide in the range of sounds, while a third set are harsh and guttural, the speaking of them (according to Payne) resembling coughing, barking, and sneezing. Powell also thinks that man lived in America before he acquired articulate speech. The utterance of these speech elements in definite order constitutes the roots and sentences of the various tongues. From the manner of assemblage, all American languages are agglutinative, or holophrastic, but they should not be called polysynthetic or incorporative or inflexional. They were more or less on the way to such organized forms, in which the world's literatures are preserved. As in all other languages, so in those of aboriginal America, the sentence is the unit. Words and phrases are the organic parts of the sentence, on which, therefore, the languages are classified. It is on this basis of sentential elements that Powell has arranged the linguistic families of North America. He has brought together, in the Bureau of Ethnology in Washington, many hundreds of manuscripts, written by travellers, traders, missionaries, and scholars; and, better still, in response to circulars, carefully-prepared vocabularies, texts, and long native stories have been written out by trained collectors. A corps of specialists—Boas, Dorsey, Gatschet, Hewitt, Mooney, Pilling—have studied many of these languages analytically and comparatively. Other institutional investigations have been prosecuted, the result of all which will be an intelligent comprehension of the philology of a primitive race.

Attention is frequently called to the large number of linguistic families in America, nearly 200 having been named, embracing over 1000 languages and dialects. A few of them, however, occupied the greater part of the lands both north and south of Panama; the others were encysted in the territory of the prevailing families, or concealed in *culs-de-sac* of the mountains. They are, through poverty of material, unclassified languages, merely outstanding phenomena. Factions separated from the parent body developed dialects or languages by contact, intermarriage, and incorporation with foreign tribes. To the old-time belief that languages

Culture provinces.

Language.

Classification.

Linguistic families.

multiplied by splitting and colonizing, must be added the theory that languages were formerly more numerous, and that those of the Americans were formed by combining.

The families of North America, Middle America, and South America are here given in alphabetical order, the prevailing ones in small capitals:—

ALGONQUIAN, E. Can., M. Atlantic States, middle States, middle Western States; ATHAPASCAN, N.W. Can., Alaska, Wash., Or., Cal., Ariz., Mex.; Attacapan, La.; Beothukan, Nova Scotia; CADDONAN, Tex., Neb., Dak.; CHIMAKUAN, Arctic province; Esselenian, Cal.; IROQUOIAN, N.Y., N.C.; Kalapooian, Or.; Karankawan, Tex.; KERESAN, N. Mex.; KIOWAN, Neb.; KITUNAHAN, Brit. Col.; KOLUSCHAN, S. Alaska; KULANAPAN, Cal.; KUSAN, Cal.; Lutuamian, Or.; Mariposan, Cal.; Moquelumnan, Cal.; MUSKHOGEAN, Gulf States; NATCHESAN, Miss.; Palaihnihan, Cal.; PIMAN, Ariz.; Pujunan, Cal.; Quotatetan, Or.; Salinan, Cal.; SALISHAN, Brit. Col.; Sastean, Or.; SHAHAPTIAN, Or.; SHOSHONEAN, Interior Basin; SIOUAN, Mo. Valley; SKITTAGETAN, Brit. Col.; Takilman, Or.; TANYOAN, Mex.; Timuquanan, Fla.; Tonikan, Miss.; Tonkawan, Tex.; Uchean, Ga.; Waiilatpuan, Or.; WAKASHAN, Vancouver I.; Washoan, Nev.; Weitspekan, Or.; Wishoskan, Cal.; Yakonan, Or.; Yanan, Or.; Yukian, Cal.; Yuman, L. Cal.; ZUNYAN, N. Mex. CHAPANECAN, Chi.; Chinantecan, Oax.; Chontalan, So. Mex.; Hautusan, Nic.; Lencan, Hon.; MAYAN, Yuc. and Guat.; NAHUATLAN, Mex.; OROMITLAN, Cen. Mex.; Raman, Hond.; Subtiaban, Nic.; TARASCAN, Mich.; Tehuantepecan, Isthmus; Tequistlatecan, Oax.; TONONAGAN, Mex.; Triquian, So. Mex.; Ulvan, Nic.; Xicaquean, Hond.; ZAPOTECAN, Oax.; ZOQUEAN, Tehuantepec.

Alikulufan, T. del Fuego; Arauan, R. Purús; ARAWAKIAN, E. Andes; Atacamanyan, S. Peru; ARAUCANIAN, Pampas; AYMARAN, Peru; Barbacoan, Colombia; Betoayan, Bogota; Canichanan, Bolivia; Caraban, S. Brazil; CARIBIAN, around Caribbean Sea; Catamarenyan, Chaco; Changuinan, Panama; Charruan, Paraná R.; CHIBCHAN, Colombia; Churoyan, Orinoco R.; Coconucan, Colombia; Cunan, Panama; GUAYCURUAN, Paraguay R.; JIVAROAN, Ecuador; KECHUAN, Peru; Laman, N.E. Peru; Lulean, Vermejo R.; Mainan, S. Ecuador; Matacoan, Vermejo R.; Mocoan, Colombia; Mosetenan, E. Bolivia; ONAN, T. del Fuego; Paniquitan, Colombia; Panoan, Ucayali R., Peru; Puquinan, Titiacaca L.; Samucan, Bolivia; Tacanan, N. Bolivia; TAPUYAN, Brazil; Timotean, Venezuela; TUPIAN, Amazon R.; TZONECAN, Patagonia; YANGAN, T. del Fuego; Yuncan, Truxillo, Peru; Yurucarian, E. Bolivia; ZAPAROAN, Ecuador.

Written language was largely hieroglyphic and heroic. The drama, the cult image, the pictograph, the synechdochic picture, the ideaglyph, were steps in a progress without a break. The warrior painted the story of conflicts on his robe only in part, to help him recount the history of his life; the Eskimo etched the prompts of his legend on ivory; the Tlinkit carved them on his totem post; the women fixed them in pottery, basketry, or blankets. At last, the central advanced tribes made the names of the abbreviated pictures useful in other connexions, and were far on the way to a syllabary. Intertribal communication was through gestures; it may be, survivals of a primordial speech, antedating the differentiated spoken languages.

To supply their wants the Americans invented modifications in natural materials, the working of which was their industries. The vast collections in richly-endowed European and American museums are the witnesses and types of these. There is danger of confounding the products of native industries. The following classes must be carefully discriminated:—(a) pre-Columbian, (b) Columbian, (c) pre-contact, (d) first contact, (e) post-contact, (f) present, and (g) spurious. Pre-Columbian or pre-historic material is further classified into that which had been used by Indians before the discovery, and such as is claimed to be of a prior geological period. Columbian, or 15th-century material, still exists in museums of Europe and America, and good descriptions are to be found in the writings of contemporary historians.

Pre-contact material is such as continued to exist in any tribe down to the time when they were touched by the presence of the trade of the whites. In some tribes this would bring the student very near to the present time; for example, before Steinen, the Indians in Matto Grosso were in the pre-contact period. Post-contact material is genuine Indian work more or less influenced by acculturation. It is interesting in this connexion to study also first contact in its lists of articles, and the effects produced upon aboriginal minds and methods. For example, a tribe that would jump at iron arrow-heads stoutly declined to modify the shafts. Present material is such as the Indian tribes of the two Americas are making to-day. Spurious material includes all that mass of objects made by whites and sold as of Indian manufacture; some of it follows native models and methods; the rest is fraudulent and pernicious. The question whether similarities in technology argue for contact of tribes, or whether they merely show corresponding stages of culture, with modifications produced by environment, divides ethnologists.

The study of mechanics involves materials, tools, processes, and products. No iron tools existed in America before the invasion of the whites. Mineral, vegetable, and animal substances, soft and hard, **Aboriginal mechanics.** were wrought into the supply of wants by means of tools and apparatus of stone, wood, and bone; tools for cutting, or edged tools; tools for abrading and smoothing the surfaces of substances, like planes, rasps, and sandpaper; tools for striking, that is, pounding for the sake of pounding, or for crushing and fracturing violently; perforating tools; devices for grasping and holding firmly. These varied in the different culture provinces according to the natural supply, and the presence or absence of good tool material counted for as much as the presence or absence of good substances on which to work. As a means of grading progress among the various tribes, the tool is valuable both in its working part and its hafting, or manual part. Fire drills were universal.

Besides chipped stone knives, the teeth of rodents, sharks, and other animals served an excellent purpose. In North-west America and in the Caribbean area the adze was highly developed. In Mexico, Colombia, and Peru the cutting of friable stone with tough volcanic hammers and chisels, as well as rude metallurgy, obtained, but the evidences of smelting are not convincing. Engineering devices were almost wanting. The Eskimo lifted his weighted boat with sheer-legs made of two paddles; he also had a tackle without sheaves, formed by reaving a greased thong through slits cut in the hide of a walrus. The North-West Coast Indians hoisted the logs that formed the plates of their house frames into position with skids and parbuckles of rope. The architectural Mexicans, Central Americans, and especially the Peruvians, had no derricks or other hoisting devices, but rolled great stones into place along prepared ways and up inclined planes of earth, which were afterwards removed. In building the fortress of Sacsahuaman, heights had to be scaled; in Tiahuanaco stones weighing 400 tons were carried seventeen miles; in the edifices of Ollantaytambo not only were large stones hauled up an ascent, but were fitted perfectly. The moving of vast objects by their simple processes shows what great numbers of men could be enlisted in a single effort, and how high a grade of government it was which could hold them together and feed them. In Arizona, Mexico, and Peru reservoirs and aqueducts prove that hydrotechny was understood.

Time-keeping devices were not common. Sun dials and calendar monuments were known among the more advanced tribes. Fractional portions of time were gauged by shadows, and time of day indicated by the position of the sun with

reference to natural features. No standards of weighing or measuring were known, but the parts of the body were the units, and money consisted in rare and durable vegetable and animal substances, which scarcely reached the dignity of a mechanism of exchange. If the interpretation of the Maya calculiform glyphs be trustworthy, these people had carried their numeral system into the hundreds of thousands, and devised symbols for recording such high numbers.

The Americans were, in most places, flesh-eaters. The air, the waters, and the land were their base of supplies, and cannibalism, it is admitted, was widespread.

Food. With this animal diet everywhere, vegetable substances were mixed, even in the boreal regions. Where the temperature allowed vegetable diet increased, and fruits, seeds, and roots were laid under tribute. Storage was common, and also the drying of ripened fruits. The most favoured areas were those where corn and other plants could be artificially produced, and there barbaric cultures were elaborated. This farming was of the rudest kind. Plots of ground were burned over, trees were girdled, and seeds were planted by means of sharpened sticks. The first year the crop would be free from weeds, the second year only those grew whose seeds were wafted or carried by birds, the third year the crop required hoeing, which was done with sticks, and then the space was abandoned for new ground. Irrigation and terrace culture were practised at several points on the Pacific slope from Arizona to Peru. The steps along which plant and animal domestication passed upwards in artificiality are graphically illustrated in the aboriginal food quest.

Except in the boreal areas the breech-clout was nearly universal with men, and the cincture or short petticoat with women. Even in Mexican and Mayan sculptures the gods are arrayed in gorgeous breech-clouts. The foot-gear in the tropics was the sandal, and passing northward the moccasin, becoming the long boot in the Arctic. Trousers and the blouse were known only among the Eskimo, and it is difficult to say how much these have been modified by contact. Leggings and skin robes took their place southward, giving way at last to the nude. Head coverings also were gradually tabooed south of the 49th parallel. Tattooing and painting the body were well-nigh universal. Labrets were worn by Eskimo, Tlinkit, Nahuatl, and tribes on the Brazilian coast. For ceremonial purposes all American tribes were expert in masquerade and dramatic apparel. A study of these in the historic tribes makes plain the motives in gorgeous Mexican sculptures.

The tribal system of family organization, universal in America, dominated the dwelling. The Eskimo underground houses of sod and snow, the Déné and Sioux bunch of bark or skin wigwams, the Pawnee earth lodge, the Iroquois long house, the Tlinkit great plank house, the Pueblo with its honeycomb of chambers, the small groups of thatched houses in tropical America, and the Patagonian toldos of skin are examples. The Indian habitation was made up of this composite abode, with whatever out-structures and garden plots were needed. A group of abodes, however joined together, constituted the village or home of the tribe, and there was added to these a town hall or large assembly structure where men gathered and gossiped, and where all dramatic and religious ceremonies were held. Powell contends that in a proper sense none of the Indian tribes were nomadic, but that governed by water-supply, bad seasons, and superstition (and discomfort from vermin must be added), even the Pueblo tribes often tore down and rebuilt their domiciles. The fur trade, the horse, the gun, disturbed the sedentary habit of American tribes. Little

attention was paid to furniture. In the smoke-infested wigwam and hut the ground was the best place for sitting or sleeping. The communal houses of the Pacific coast had bunks. The hammock was universal in the Tropics, and chairs of wood or stone. Eating was from the pot, with the hand or spoon. Tables, knives, forks, and other prandial apparatus were as lacking as they were in the palaces of kings a few centuries before.

Stone-working was universal in America. The tribes quarried by means of crowbars and picks of wood and bone. They split the silicious rocks with stone hammers, and then chipped them into shape with bone tools. Soap-stone for pottery was partly cut into the desired shape in the native ledge, broken or prised loose, and afterwards scraped into form. Paint was excavated with the ubiquitous digging-stick, and rubbed fine on stones with water or grease. For polished stonework the material was pecked by blows, ground with other stones, and smoothed with fine material. Sawing was done by means of sand or with a thin piece of harder stuff. Boring was effected with the sand-drill; the hardest rocks may have been pierced with specially hard sand. At any rate stones were sawed, shaped, polished, carved, and perforated, not only by the Mexicans, but among other tribes. For building purposes stones were got out, dressed, carved, and sculptured with stone hammers and chisels made of hard and tenacious rock. Stonecutters' tools of metal are not known to have existed, and they were not needed. Their quarrying and stone-working was most wasteful. Those localities where chipping was done reveal hundreds of tons of splinters and failures, and these are often counted as ruder implements of an earlier time. The dressed stones for great buildings were pecked out of the ledges, and broken off with levers in pieces much too large for their needs.

Metals were treated as malleable stones by the American aborigines. No evidence of smelting ores with fluxes is offered, but casting from metal melted in open fires is assumed. Gold, silver, copper, pure or mixed with tin or silver, are to be found here and there in both continents, and nuggets were objects of worship. Tools and appliances for working metals were of the rudest kind, and if moulds for casting were employed these were broken up; at least no museum contains samples of them, and the processes are not described. In the Arctic and Pacific coast provinces, about Lake Superior, in Virginia and North Carolina, as well as in ruder parts of Mexico and South America, metals were cold-hammered into plates, weapons, rods, and wire, ground and polished, fashioned into carved blocks of hard, tenacious stone by pressure or blow, overlaid, cold-welded, and plated. Soldering, brazing, and the blowpipe in the Cordilleran provinces are suspected, but the evidence of their existence must be further examined. A deal of study has been devoted to the cunning Tubal Cains, the surprising productions of whose handiwork have been recovered in the art provinces of Mexico and the Cordilleras, especially in Chiriqui, between Costa Rica and Colombia. It must be admitted, however, that both the tools and the processes have escaped the archæologist, as they did "the ablest goldsmiths in Spain, for they never could conceive how they had been made, there being no sign of a hammer or an engraver or any other instrument used by them, the Indians having none such" (Herrera).

The potter's wheel did not exist in the Western world, but it was almost invented. Time and muscle, knack and touch, a trained eye and brain, and an unlimited array of patterns hanging on fancy's walls, aided by a box of dry sand, were competent to give the charming results. No more striking contrast can be found between

forlorn conditions and refined art products. Art in clay was far from universal in the two Americas. The Eskimo on Bering Sea had learned to model shallow bowls for lamps. No pottery existed in Athapascan boundaries. Algonkin-Iroquois tribes made creditable ware in South-eastern Canada and Eastern United States. Muskhogean tribes were potters, but Siouan tribes, as a rule, in all the Mississippi drainage were not. In their area, however, dwelt clay-working tribes, and the Mandans had the art. Moreover, the mound-builders in the eastern half of this vast plain, being sedentary, were excellent potters. In the Muskhogee province the tribes were more settled, making clay vessels possible. On the Pacific side of the continent not one of the forty linguistic families made pottery. The only workers in clay west of the Rockies and north of the Pueblo country belonged to the Shoshonean family in the interior basin.

The study of Indian textiles includes an account of their fibres, tools, processes, products, ornaments, and uses. Their fibres were either animal or vegetable; animal fibres were hair, fur on the skin, feathers, hide, sinew, and intestines; vegetable fibres were stalks of small trees, brush, straw, cotton, bast, bark, leaves, and seed vessels in great variety as one passes from the north southward through all the culture provinces. The products of the textile industry in America were bark cloth, wattling for walls, fences and weirs, paper, basketry, matting, loom products, needle or point work, net-work, lace-work, and embroidery. In the manufacture of these the substances were reduced to the form of slender filaments, shreds, rods, splints, yarn, twine, and sennit or braid. All textile work was done by hand; the only devices known were the bark-peeler, the shredder, the flint-knife, the spindle, the rope-twister, the bodkin, the warp-beam, and the most primitive harness. The processes involved were gathering the raw material, shredding, splitting, gouging, wrapping, twining, spinning, and braiding. Twining and spinning were done with the fingers of both hands, with the palm on the thigh, with the spindle, and with the twister. Ornamentation was in form, colour, technical processes, and dyes. The uses to which the textiles were put were for clothing, furniture for the house, utensils for a thousand industries, fine arts, social functions, and worship.

In order to comprehend the more intricate processes of the higher peoples it is necessary to examine the textile industry in all of the culture areas. It is essentially woman's work. The Eskimo woman did not weave, but was expert in sewing and embroidering with sinew thread by means of a bodkin. The Déné peoples used strips of hide for snowshoes and game-bags, sewed their deerskin clothing with sinew thread, and embroidered in split quill. Their basketry, both in Canada and in Arizona, was coiled work. The northern Algonkin and Iroquoian tribes practised similar arts, and in the Atlantic States wove robes of animal and bird skins by cutting the latter into long strips, winding these strips on twine of hemp, and weaving them by the same processes employed in their wicker basketry. Textile work in the Sioux province was chiefly the making of skin garments with sinew thread, but in the Gulf States the existence of excellent cane and grasses gave opportunity for several varieties of weaving. On the Pacific coast of America the efflorescence of basketry in every form of technic was known. This art reached down to the borders of Mexico. Loom-weaving in its simplest form began with the Chilkats of Alaska, who hung the warp over a long pole, and wrought mythological figures into their gorgeous blankets by a process resembling tapestry work. The forming of bird skins, rabbit skins, and feathers into robes, and all basketry stitches, existed from Vancouver Island to Central America. In

Northern Mexico net-work, rude lace-work in twine, are followed farther south, where finer material existed, by figured weaving of most intricate type and pattern; warps were crossed and wrapped, wefts were omitted, and texture changed, so as to produce marvellous effects upon the surface. This composite art reached its climax in Peru, the llama wool affording the finest staple on the whole hemisphere. Textile work in other parts of South America did not differ from that of the Southern States of the Union. The addition of brilliant ornamentation in shell, teeth, feathers, wings of insects, and dyed fibres completed the round of the textile art. A peculiar type of coiled basketry is found at the Strait of Magellan, but the motives are not American.

Since most American tribes lived upon flesh, the activities of life were associated with the animal world. These activities were not confined to the land, but had to do also with those littoral meadows where *Zootechny*. invertebrate and vertebrate marine animals fed in unlimited numbers. An account of savage life, therefore, includes the knowledge of the animal life of America and its distribution, regarding the continent, not only as a whole, but in those natural history provinces and migrations which governed and characterized the activities of the peoples. This study would include industries connected with capture, those that worked up into products the results of capture, the social organizations and labours which were involved in pursuit of animals, the language, skill, inventions, and knowledge resulting therefrom, and, finally, the religious conception united with the animal world, which has been named zootheism. In the capture of animals would be involved the pedagogic influence of animal life; the engineering embraced in taking them in large numbers; the cunning and strategy necessary to hunters so poorly armed giving rise to disguises and lures of many kinds. Capture begins among the lower tribes with the hand, without devices, developing knack and skill in seizing, pursuing, climbing, swimming, and maiming without weapons; and proceeds to gathering with devices that take the place of the hand in dipping, digging, hooking, and grasping; weapons for striking, whether clubs, missiles, or projectiles; edged weapons of capture, which were rare in America; piercing devices for capture, in lances, barbed spears, harpoons, and arrows; traps for enclosing, arresting, and killing, such as pens, cages, pits, pen-falls, nets, hooks, nooses, clutches, adhesives, deadfalls, impalers, knife traps, and poisons; animals consciously and unconsciously aiding in capture; fire in the form of torches, beacons, burning out and smoking out; poisons and asphyxiators; the accessories to hunting, including such changes in food, dress, shelter, travelling, packing, mechanical tools, and intellectual apparatus as demanded by these arts. Finally, in this connexion, the first steps in domestication, beginning with the improvement of natural corrals or spawning grounds, and hunting with trained dogs and animals. Zootechnic products include food, clothing, ornaments, habitations, weapons, industrial tools, textiles, money, &c.

In sociology the dependence of the American tribes upon the animal world becomes most apparent. A great majority of all the family names in America were from animal totems. The division of labour among the sexes was based on zootechny. Labour organizations for hunting, communal hunt, and migrations had to do with the animal world.

In the duel between the hunter and the beast-mind the intellectual powers of perception, memory, reason, and will were developed; experience and knowledge by experience were enlarged, language and the graphic arts were fostered, the inventive faculty was evoked and developed, and primitive science was fostered in the unfolding of numbers,

metrics, clocks, astronomy, history, and the philosophy of causation. Beliefs and practices with reference to the heavenly world were inspired by zoic activities; its location, scenery, and environment were the homes of beast gods. It was largely a zoopantheon; thus zootheism influenced the organization of tribes and societies in the tribes. The place, furniture, liturgies, and apparatus of worship were hereby suggested. Myths, folk-lore, hunting charms, fetishes, superstitions, and customs were based on the same idea.

Excepting for extensive and rapid travel over the snow in the Arctic regions by means of dog sleds, the extremely limited transportation by dog travail (or sledge) *Travel.* in the Sioux province, and the use of the llama as a beast of burden throughout the Peruvian highlands, land travel was on foot, and land transportation on the backs of men and women. One of the most interesting topics of study is the trails along which the seasonal and annual migrations of tribes occurred, becoming in Peru the paved road, with suspension bridges and wayside inns or tambos. In Mexico, and in Peru especially, the human back was utilized to its utmost extent, and in most parts of America harness adapted for carrying was made and frequently decorated with the best art. In the Mexican codices pictures of men and women carrying are plentiful. Traveling on the water was an important activity in aboriginal times. Hundreds of thousands of miles of inland waters and archipelagoes were traversed. Commencing in the Arctic region, the Eskimo in his kayak, consisting of a framework of drift wood or bone covered with dressed sealskin, could paddle down East Greenland, up the west shore to Smith Sound, along Baffin Land and Labrador, and the shores of Hudson Bay throughout insular Canada and the Alaskan coast, around to Mount St Elias, and for many miles on the eastern shore of Asia. In addition to this most delicate and rapid craft, he had his umiak or freight boat, sometimes called woman's boat. The Athapascan covered all North-western Canada with his open birch-bark canoe, somewhat resembling the kayak in finish. The Algonkin-Iroquois took up the journey at Bear Lake and its tributaries, and by means of paddling and portages traversed the area of Middle and Eastern Canada, including the entire St Lawrence drainage. The absence of good bark, dugout timber, and chisels of stone, deprived the whole Mississippi Valley of creditable watercraft, and reduced the natives to the clumsy trough for a dugout and miserable bull-boat, made by stretching dressed buffalo hide over a crate. On the Atlantic coast of the United States the dugout was improved in form where the waters were more disturbed. John Smith's Indians had a fleet of dugouts. The same may be said of the Gulf States tribes, although they added rafts made of reed. Along the archipelagoes of the North Pacific coast, from Mount St Elias to the Columbia river, the dugout attained its best. The Columbia river canoe resembled that of the Amur, the bow and stern being pointed at the water line. Poor dugouts and rafts, made by tying reeds together, constituted the watercraft of California and Mexico until Central America is reached.

The Caribs were the Haidas of the Caribbean Sea and Northern South America. Their craft would vie in form, in size, and seaworthiness with those of the North Pacific coast. The catamaran and the reed boat were known to the Peruvians. The tribes of Venezuela and Guiana, according to Im Thurn, had both the dugout and the built-up hull. The simplest form of navigation in Brazil was the woodskin, a piece of bark stripped from a tree, and crimped at the ends. The sangada, with its platform and sail, belonging to the Brazilian coast, is spoken of as a good seaworthy

craft. Finally, the Fuegian bark canoe, made in three pieces so that it can be taken apart and transported over hills and sewed together, ends the series. The American craft was propelled by poling, paddling, and by rude sails of matting.

The æsthetic arts of the American aborigines cannot be studied apart from their languages, industries, social organizations, lore, and worships. Art was limited most of all by poverty in technical appliances. *Fine art.* There were just as good materials and inspirations, but what could the best of them do without metal tools? One and all, skilful to a surprising degree—weavers, embroiderers, potters, painters, engravers, carvers, sculptors, and jewellers—they were wearied by drudgery and overpowered by a never-absent, weird, and grotesque theology. The Eskimo engraved poorly, the Déné embroidered, the North Pacific tribes carved skilfully in horn, slate, and cedar, the California tribes had nimble fingers for basketry, the Sioux, like the Mexicans, gloried in feathers. The mound builders, Pueblo tribes, middle Americans, and Peruvians, were potters of many schools, gorgeous colour fascinated the Amazonians, the Patagonians delighted in skins, and even the Fuegians saw beauty in the pretty snail shells of their desolate island shores. Of the Mexican and Central American sculpture and architecture a competent judge says that Yucatan and the southern states of Mexico are not rich in sculptures, apart from architecture; but in the valley of Mexico the human figure, animal forms, fanciful life motives in endless variety, were embodied in masks, yokes, tablets, calendars, cylinders, disks, boxes, vases, and ornaments. The Nahuatl lapidary had at hand many varieties of workable and beautiful stone; onyx, marble, limestone, quartz and quartz crystal, granite, syenite, basalt, trachyte, rhyolite, diorite, and obsidian, the best of material prepared for them by nature; while the Mayas had only limestone, and hard, tenacious rock with which to work it, and timber for burning lime. However, looking over the whole field of North American achievement, architectural and non-architectural, composite and monolithic, the palm for boldness, magnitude of proportions, and infinity of labour, must go to the sculptured mosaics of Yucatan. Maya architecture is the best remaining index of the art achievements of the American race. The construction of such buildings as the palace at Uxmal and the castillo at Chichen indicates a mastery in architectural design. There is lack of unity in plan and grouping, and an enormous waste of material as compared with available room. At Uxmal the mass of masonry is to chamber space about as forty to one. The builders were "ignorant of some of the most essential principles of construction, and are to be regarded as hardly more than novices in the art" (Holmes). As for the marvels of Peru, the walls of the temple of the sun in Cuzco, with their circular form and curve inward, from the ground upward, are most imposing. Some of the gates without lintels are beautiful, and the geometric patterns in the walls extremely effective. The same objection to over-massiveness might not apply here as in Mexico, owing to volcanic activity.

Institutions in Europe and America have gathered abundant material for an intelligent comprehension of American Indian sociology. The British Association has had a committee reporting during *Sociology.* many years on the tribes of North-west Canada. The American Museum in New York has prepared a series of monographs on the tribes of the North Pacific coast, of Northern Mexico, and of the Cordilleras of South America. The reports of the Bureau of Ethnology in Washington cover the Eskimo, east and west, and all the tribes of the United States. In Mexico the former labourers of Pimentel and Orozco y Berra are supplemented by those of Bandelier,

Peñafiel, Herrera, and Cicero. Otto Stoll's studies in Guatemala, Berendt's in Central America, Ernst's in Venezuela, Im Thurn's in Guiana, those of Ehrenreich, von den Steinen, Meyer in Brazil, or of Bandelier, Bastian, Brühl, Middendorf, von Tschudi in Peru, afford the historian of comparative sociology ample groundwork for a comprehensive grasp of South American tribes. In all parts of the western hemisphere society was organized on cognate kinship, real or artificial, the unit being the clan. There were tribes where the basis of kinship was agnate, but these were the exceptions. The headship of the clan was sometimes hereditary, sometimes elective, but each clan had a totemic name, and the clans together constituted the tribe, the bond being not land, but blood. Women could adopt prisoners of war, in which case the latter became their younger sons. When a confederacy was organized under a council, intermarriage between tribes sometimes occurred; an artificial kinship thus arose, in which event the council established the rank of the tribes as elder and younger brother; grandfather, father, and sons, rendering the relationship and its vocabulary most intricate, but necessary in a social system in which age was the predominant consideration and etiquette most exacting.

The Eskimo have a regular system of animal totem marks and corresponding gentes. Powell sets forth the laws of real and artificial kinship among the North American tribes, as well as tribal organization and government, the formation of confederacies, and the intricate rules of artificial kinship by which rank and courtesies were established. Bandelier declares that in Mexico existed neither state nor nation, nor political society of any kind, but tribes representing dialects, and autonomous in matters of government, and forming confederacies for the purposes of self-defence and conquest. The ancient Mexican tribe was composed of twenty autonomous kins. According to Brinton the social organization of ancient Peru was a government by a council of the gentes. The Inca was a war chief elected by the council to carry out its commands. Among the Caribs a like social order prevailed; indeed, their family system is identical with the totem system of North American Indians. Dominated by the rule of blood relationship, the Indians regulated all co-operative activities on this basis. Not only marriage, but speech and common industries, such as rowing a boat or chasing a buffalo, were under its sway. It obtrudes itself in fine art, behaviour, law-making, lore, and religion. In larger or smaller numbers of cognate kindred, for shorter or longer periods of time, near or far from home, the aborigines developed their legislatures, courts, armies, secret societies, and priesthoods.

In organization, engineering, strategy, offence, and defence, the art of war was in the barbarous and the savage status or grade. One competent to judge asserts that peace, not war, was the normal intertribal habit. They held frequent intercourse, gave feasts and presents, and practised unbounded hospitality. Through this traffic objects travelled far from home, and now come forth out of the tombs to perplex archæologists. Remembering the organization of the tribe everywhere prevalent, it is not difficult to understand that the army, or horde, that stands for the idea, was assembled on the clan basis. The number of men arrayed under one banner, the time during which they might cohere, the distances from home they could march, their ability to hold permanently what they had gained, together form an excellent metric scale of the culture grade in the several American provinces, and nowhere, even in the most favoured, is this mark high. With the Mexicans war was a passion, but warfare was little above the raid (Bandelier). The lower tribes

hunted their enemies as they hunted animals. In their war dances, which were only rehearsals, they disguised themselves as animals, and the pantomime was a mimic hunt. They had striking, slashing, and piercing weapons held in the hand, fastened to a shaft or thong, hurled from the hand, from a sling, from an atlatl or throwing-stick, or shot from a bow. Their weapons were all individual, not one co-operative device of offence being known among them, although they understood fortification.

The term "slavery" is often applied to the aboriginal American tribes. The truth of this depends upon the definition of the word "slave." If it means the capture of men, and especially of women, and adoption into the tribe, this existed everywhere; but if subjection to a personal owner, who may compel service or sell the individual, slavery was far from universal. Nieboer finds it only on the North Pacific coast, as far south as Oregon, among the Navajo and the Cibola pueblos, and in a few tribes of Middle and South America.

The thought life of the American aborigines is expressed in their practical knowledge and their lore. The fascination which hangs around the latter has well-nigh obscured the former. As in medicine Lore. theory is one thing and practice another, so among these savages must the two be carefully discriminated. Dorsey, again, draws a distinction between lore narratives, which can be rehearsed without fasting or prayer, and rituals which require the most rigid preparation. In each culture province the Indians studied the heavenly bodies. The Arctic peoples regulated their lives by the long day and night in the year; among the tribes in the arid region the place of sunrise was marked on the horizon for each day; the tropical Indians were not so observant, but they worshipped the sun god above all. The Mayas had a calendar of 360 days, with intercalary days; this solar year was intersected by their sacred year of twenty weeks of thirteen days each, and these assembled in bewildering cycles. Their knowledge of the air and its properties was no less profound. Heat and cold, rain and drought, the winds in relation to the points of the compass, were nearest their wants and supplies, and were never out of their thoughts. In each province they had found the best springs, beds of clay, paint, soapstone, flinty rock, friable stone for sculpture, and hard, tenacious stone for tools, and used ashes for salt. The vegetal kingdom was no less familiar to them. Edible plants, and those for dyes and medicines, were on their lists, as well as wood for tools, utensils, and weapons, and fibres for textiles. They knew poisonous plants, and could eliminate noxious properties. The universal reliance on animal life stimulated the study of the animal kingdom. Everywhere there were names for a large number of species; industries and fine arts were developed through animal substances. Society was organized in most cases on animal clans, and religion was largely zoomorphic. The hunting tribes knew well the nature and habits of animals, their anatomy, their migrations, and could interpret their voices. Out of this practical knowledge, coupled with the belief in personicity, grew a folk-lore so vast that if it were written down the world would not contain the books.

The religion of the American aborigines, so far as it can be made a subject of investigation, consisted (1) in what the tribes believed about spirits, or shades, and the spirit world—its organization, place, activities, and relation to our world; and (2) in what they did in response to these beliefs. The former was their creeds, the latter their cults or worships. In these worships, social organization, religious dramas and paraphernalia, amusement and gambling, and private religion or fetichism, found place. In order to obtain an intelligent grasp of

Art of war.

Religion.

the religion of tribes in their several culture provinces, it must be understood: (1) That the form of belief called *animism* by Tylor (more correctly speaking, *personality*), was universal; everything was somebody, alive, sentient, thoughtful, wilful. This personality lifts the majority of earthly phenomena out of the merely physical world and places them in the spirit world. Theology and science are one. All is supernatural, *wakañ*. (2) That there existed more than one self or soul or shade in any one of these personalities, and these shades had the power not only to go away, but to transform their bodily tenements at will; a bird, by raising its head, could become a man; the latter, by going on all fours, could become a deer. (3) That the regulative side of the spirit world was the natural outcome of the clan social system and the tribal government in each tribe. Even one's personal name had reference to the world of ghosts. The affirmation that American aborigines believed in an all-pervading, omnipotent Spirit is entirely inconsistent with the very nature of the case. (4) Worship was everywhere dramatic. Only here and there among the higher tribes were bloody sacrifices in vogue, and prayers were in pantomime.

In the culture areas the environment gave specific characters to the religion. In the Arctic province the overpowering influence of meteorological phenomena manifested itself both in the doctrine of shades and in their shamanistic practices. The raven created the world. The Déné myths resemble those of the Eskimo, and all the hunting tribes of Eastern Canada and United States and the Mississippi Valley have a mythology based upon their zootechny and their totemism. The religious conceptions of the fishing tribes on the Pacific coast between Mount St Elias and the Columbia river are worked out by Boas; the transformation from the hunting to the agricultural mode of life was accompanied by changes in belief and worship quite as radical. These have been carefully studied by Cushing, Stevenson, and Fewkes. The pompous ceremonials of the civilized tribes of Mexico and the Cordilleras in South America, when analysed, reveal only a higher grade of the prevailing idea. Im Thurn says of the Carib: "All objects, animate and inanimate, seem exactly of the same nature, except that they differ in the accident of bodily form." These mythological ideas and symbols of the American aborigines were woven in their textiles, painted on their robes and furniture, burned into their pottery, drawn in sand mosaics on deserts, and perpetuated in the only sculptures worthy of the name, in wood and stone. They are inseparable from industry; language, social organization, and custom wait upon them: they explain the universe in the savage mind.

The archæology of the western hemisphere should be divided as follows: (1) that of Indian activities; (2) the question of man's existence in a prior geological period. There is no dividing line between first-contact ethnology and pre-contact archæology. Historians of this time, both north and south of Panama, described tools and products of activities similar to those taken from beneath the soil near by. The archæologist recovers his specimens from waste places, cave deposits, abandoned villages, caches, shell-heaps, refuse heaps, enclosures, mounds, hut rings, earthworks, garden beds, quarries and workshops, petroglyphs, trails, graves and cemeteries, cliff and cavate dwellings, ancient pueblos, ruined stone dwellings, forts and temples, canals or reservoirs. The relics found in these places are material records of language, industries, fine arts, social life, lore, and religion.

Here and there in the Arctic province remains of old village sites have been examined, and collections brought

away by whalers and exploring expeditions. Two facts are established—namely, that the Eskimo lived formerly farther south on the Atlantic coast, and that, aboriginally, they were not specially adept in carving and etching. The old apparatus of hunting and fishing is quite primitive. The Déné province in Alaska and North-western Canada yields nothing to the spade. Algonkin-Iroquois Canada, thanks to the Geological Survey and the Department of Education in Ontario, has revealed old Indian camps, mounds, and earthworks along the northern drainage of Lakes Erie and Ontario, and pottery in a curved line from Montreal to Lake of the Woods. Throughout Eastern United States shell-heaps, quarries, workshops, and camp sites are in abundance. The Sioux and the Muskogee province is the mound area, which extends also into Canada along the Red river. The forms of these are earth-heaps, conical mounds, walls of earth, rectangular pyramids, and effigies. Thomas sums up the work of the Bureau of Ethnology upon the structure, contents, and distribution of these earth monuments, over a vast area from which adobe, building stone, and stone-working material were absent. No writings have been recovered, the artisans shaping small objects in stone were specially gifted, the potters in only a few places approached those of the Pueblos, the fine art was poor, and relics found in the mounds do not indicate in their makers a grade of culture above that of the Indian tribes near by. The archæology of the Pacific slope, from the Aleutian Islands, is written in shell-heaps, village sites, caves, and burial-places. The relics of bone, antler, stone, shell, and copper are of yesterday. Even the Calaveras man is no exception, since his skull and his polished conical pestle, the latter made of stone more recent than the auriferous gravels, show him to have been of Digger Indian type. In Utah begin the ruins of the Pueblo culture. These cover Arizona and New Mexico, with extensions into Colorado on the north and Mexico on the south. The reports of work done in this province for several years past form a library of text and illustration. Cliff dwellings, cavate houses, pueblos, and casas are all brought into a series without a break by Bandelier, Cushing, Fewkes, Holmes, Mindelleff, Nordenskiöld, Powell, and Stevenson. From Casa Grande, in Chihuahua, to Quemada, in Zacatecas, Lumholtz found survivals of the cliff dwellers. Between Quemada and Copan, in Honduras, is an unbroken series of mural structures. The traditions agree with the monuments, whatever may be objected to assigning any one ruin to the Toltec, the Chichimec, or the Nahuatl, that there are distinct varieties in ground-plan, motives, stone-craft, wall decorations, and sculptures. Among these splendours in stone the following recent explorers must be the student's guide:—Charnay, Förstemann, Goodman, Gordon, Holmes, Maudslay, Mercer, Sapper, Saville, Selser, Thomas, Thompson. A list of the ruins, printed in the handbook on Mexico published by the Department of State in Washington, covers several pages. The special characteristics of each are to be seen partly in the skill and genius of their makers, and partly in the exigencies of the site and the available materials. A fascinating study in this connexion is that of the water-supply. The cenotes or underground reservoirs were the important factors in locating the ruins of Northern Yucatan. From Honduras to Panama the urn burials, the pottery, the rude carved images, and, above all, the grotesque jewellery, absorb the archæologist's attention.

Beyond Chiriqui southward is El Dorado. Here also bewildering products of ancient metallurgy tax the imagination as to the processes involved, and questions of acculturation also interfere with true scientific results. The fact remains, however, that the curious metal craft of the

narrow strip along the Pacific from Mexico to Titicaca is the greatest of archæological enigmas. Bandelier, Holmes, Seler, and Uhle have taken up the questions anew. Beyond Colombia are Ecuador and Peru, where, in the widening of the continent, architecture, stone-working, pottery, metallurgy, textiles, are again exalted. Among the Cordilleras in their western and interior drainages, over a space covering more than twenty degrees of latitude, the student comes again upon massive ruins. The materials on the coast were clay and gravel, wrought into concrete, sun-dried bricks, and pisé or rammed work, cut stalks of plants formed with clay a kind of staff, and lintels were made by burying stems of caña brava (*Gynerium saccharoides*) in blocks of pisé. On the uplands structures were of stone laid up in a dozen ways. Walls for buildings, garden terraces, and aqueducts were straight or sloping. Doorways were usually square, but corbelled archways and gateways surmounted with sculptures were not uncommon. Ornamentation was in carving and in colour, the latter far more effectively used than in Middle America. A glance at the exquisite textiles reveals at once the inspiration of mural decorations. The most prolific source of Peruvian relics is the sepulchres or huacas, the same materials being used in their construction as in building the houses. Here, owing to a dry climate, are the dead, clad and surrounded with food, vessels, tools, and art products, as in life. The textiles and the pottery can only be mentioned; their quality and endless varieties astonish the technologist. In the Carib province there are no mural remains, but the pottery, with its excessive on-laying, recalls Mexico and the jewellers of Chiriqui. The polished stone work is superb, finding its climax in Puerto Rico, which seems to have been the sacred island of the Caribs. For the coasts of South America the vast shell-heaps are the repositories of ancient history.

Since 1880 organized institutions of anthropology have taken the spade out of the hands of individual explorers in order to know the truth concerning Glacial or Pleistocene man. The geologist and the trained archæologist are associated. In North America the sites have been examined by the Peabody Museum and the Bureau of Ethnology, with the result that only the Trenton gravels have any standing. The so-called palæolithic implements are everywhere. The question is one of geology, simply to decide whether those recovered at Trenton are ancient. Putnam and Wright maintain that they are ancient, Chamberlain and Holmes that they are post-Glacial, and comparatively recent. In South America the shell-heaps, of enormous size, are supposed to show that the animals have undergone changes in size and that such vast masses require untold ages to accumulate. The first is a biological problem. As for the second, the elements of savage voracity and wastefulness, of uncertainty as to cubical contents on uneven surface, and of the number of mouths to fill, make it hazardous to construct a chronological table on a shell heap. Hudson's village sites in Patagonia contain pottery, and that brings them all into the territory of Indian archæology. Ameghino refers deposits in Patagonia, from which undoubted human bones and relics have been exhumed, to the Miocene. The question is of the age of the sediments from which these were taken. The

bones of other associated animals, says Hatcher, demonstrate the Pleistocene nature of the deposits, by which is not necessarily meant older Quaternary, for their horizons have not been differentiated and correlated in South America. Hatcher believes that "there is no good evidence in favour of a great antiquity for man in Patagonia." In a cave near Consuelo Cove, southern Patagonia, have been found fragments of the skin and bones of a large ground-sloth, *Grypotherium (Neomylodon) listai*, associated with human remains. Ameghino argues that this creature is still living, while Dr Moreno advances the theory that the animal has been extinct for a long period, and that it was domesticated by a people of great antiquity, who dwelt there prior to the Indians. Hauthal, Roth, and Nitsche review their work with the conclusion, not unanimously held by them, that man co-existed here with all the other animals whose remains were found during an inter-Glacial period. Woodward reviews the question in *Proceedings of the Zoological Society of London*, closing with this sentence: "If we accept the confirmatory evidence afforded by Mr Spencer Moore, we can hardly refuse to believe that this ground-sloth was kept and fed by an early race of men." These are individual opinions, subject to revision by that court of appeals, the institutional judgment.

AUTHORITIES.—A valuable endowment of research in specimens, literature, and pictures, deposited in libraries, museums, and galleries since 1880 will keep ethnologists and archæologists employed for many years to come. The scientific inquirer will find a mass of material in the papers and reports contributed to the various societies and institutions which are devoted to anthropological research. The following short list of works includes, however, a few authorities which have made use of recent discoveries generally:—H. H. BANCROFT. *Native Races of the Pacific States of North America*, vols. i.-v. 1874-1876. New York.—D. G. BRINTON. *Library of Aboriginal American Literature*, vols. i.-viii. 1882-1890. Philadelphia. *The American Race*. New York, 1891.—GUSTAV BRÜHL. *Die Culturvölker Amerikas*. Cincinnati, 1889.—DÉSIRÉ CHARNAY. *The Ancient Cities of the New World*. New York, 1887.—F. S. DELLENBAUGH. *The North Americans of Yesterday*. New York, 1901.—J. DENIKER. *The Races of Man*. London, 1900.—PAUL EHRENREICH. *Die Völkerstämme Brasiliens*. Berlin, 1892. *Anthropologische Studien über die Urbewohner Brasiliens*. Berlin, 1897.—J. W. FEWKES. *A Journal of American Ethnology and Archæology*, vols. i.-iv. Boston, 1891-94.—E. FÖRSTEMANN. *Zur Entzifferung der Maya Handschriften*, Paris i.-vii. Dresden, 1880, 1898. *Die Maya-Handschrift der Königl. öffentl. Bibliothek zu Dresden*. Leipzig, 1880; Dresden, 1891.—E. F. IM THURN. *Among the Indians of Guiana*. London, 1883.—A. H. KEANE. *Ethnology*. Cambridge, 1896. *Man, Past and Present*. Cambridge, 1899.—WASHINGTON MATTHEWS. *Navajo Legends*. Cambridge, Mass., 1897.—ANNE CARY MAUDSLAY and ALFRED PERCIVAL. *A Glimpse at Guatemala, and some Notes on the Ancient Monuments of Central America*. London, 1899.—H. C. MERCER. *The Hill Caves of Yucatan*. Philadelphia, 1896.—MARQUIS DE NADAILLAG. *L'Amérique préhistorique*. Paris, 1883.—H. J. NIEBOER. *Slavery as an Industrial System*. Ethnological researches. The Hague, 1900.—G. NORDENSKIÖLD. *The Cliff Dwellers of the Mesa Verde, Colorado*. Stockholm, 1893.—EDWARD JOHN PAYNE. *History of the New World called America*, vol. i. 1892, vol. ii. 1899. Oxford.—DÉSIRÉ PECTOR. *Notes sur l'Américanisme; Quelques-unes de ses lacunes en 1900*. Paris, 1900.—J. W. POWELL. *The United States of America*. Ed. by N. S. SHALER. New York, 1894.—CYRUS THOMAS. *Introduction to the Study of North American Archæology*. Cincinnati, 1898.—JUSTIN WINSOR. *Narrative and Critical History of America*. Boston, 1889.—G. F. WRIGHT. *The Ice Age in North America*. New York, 1896.

(O. T. M.)

America Islands. See POLYNESIA.

American Literature. See under UNITED STATES.

Americus, a city of Georgia, U.S.A., the capital

of Sumter county, situated in the south-western part of the state at an altitude of 360 feet. It is in an agricultural region which produces cotton and corn, and is on the Central of Georgia and the Georgia and Alabama railways. The population in 1880 was 3635, in 1890 it was 6398, and in 1900 it was 7674.

Amersham, or AGMONDESHAM, a market-town and railway station in the Wycombe parliamentary division of Buckinghamshire, England, 26 miles W.N.W. of London. Area of parish, 6119 acres. Population (1881), 2500; (1901), 3209. Rural district area, 39,800 acres; population (1891), 12,501; (1901), 13,541.

Amesbury, a town of Essex county, Massachusetts, U.S.A., situated in north-eastern Massachusetts on the north bank of the Merrimac river, six miles from its mouth. Its area is fourteen square miles and its surface is hilly. The principal village, bearing the same name as the town, and noted as being the home of Whittier, lies at the mouth of the Powow river, and is on the Boston and Maine railway. The population of the town (1880) was 3355; (1890), 9798; (1900), 9473.

Amhara. See ABYSSINIA.

Amherst, a district and town within the Tenasserim division of Lower Burma, lying between the Indian Ocean and the hills which separate Burma from Siam. The area of the district is 7062 square miles, with, in 1891, a population of 233,539. The number of villages in the district was 660, and the revenue paid in 1898-99 was Rs.8,76,819. In 1891 the population comprised 191,241 Buddhists and Jains, 19,415 Hindus, 15,611 Mahomedans, 2897 aborigines, mostly Karens, and 4374 Christians. Of the total area of 4,519,680 acres, there were 312,908 acres under cultivation in 1898-99, 14,594 acres were fallow, 77,912 acres were cultivable, and 3,670,276 acres were not capable of cultivation. The chief town is Moulmein, with a population of 55,785. AMHERST TOWN, about 30 miles to the south, has not grown to any appreciable extent and remains a mere bathing-place for Moulmein. The rainfall for the district in 1898-99 was 199.58 inches. This is below the average.

Amherst, the county town of Cumberland county and port of entry in Nova Scotia, at the head of Chignecto Bay and on the Intercolonial railway, 138 miles from Halifax. It contains county and railway buildings, six churches, an iron foundry and several factories, and shops for the manufacture of railway carriages. In 1900 the exports were \$338,525, and the imports \$219,422. The population in 1891 was 3781, and was estimated in 1900 at 5600.

Amherst, a town of Hampshire county, in central Massachusetts, U.S.A., with an area of 26 square miles. It is situated on the east side of Connecticut Valley, immediately north of Holyoke Range. The village of the same name is entered by two railways, the Boston and Maine and the Central Vermont. Amherst College had in 1899 a faculty of 32 professors and instructors, and was attended by 380 students. Its property was valued at \$2,400,000, and its income was \$100,000. The state Agricultural College had in 1899 a teaching staff of 19 professors and 140 students. The population in 1880 was 4298, in 1890 it was 4512, and in 1900 it was 5028.

Amiel, Henri Frédéric (1821-1881), Swiss philosopher and critic, was born at Geneva, 27th September 1821. He was descended from a Huguenot family which had been driven to Switzerland by the revocation of the Edict of Nantes. He lost both his parents at an early age; when he grew up he devoted himself principally to travel, mingling with the most intellectual circles throughout Europe, and in particular studying German philosophy at Berlin. In 1849 he was appointed professor of æsthetics at the academy of Geneva, and in 1854 became professor of moral philosophy. Notwithstanding his high qualifications, these appointments turned out unfortunately for him. They had been conferred by the democratic party,

then dominant in Geneva, and he was in consequence entirely ignored by the aristocratic party, which comprised nearly all the culture and refinement of the city. This painful isolation nevertheless inspired the one book by which Amiel lives, the *Journal Intime*, which, published after his death, obtained a European reputation and was translated into English by Mrs Humphry Ward. Did not "second-rate" seem to imply a slur, this book might be well described by the title of one of Tennyson's early poems, "The Confessions of a Second-rate Sensitive Mind ill at ease with itself." Although, however, second-rate as regarded productive power, Amiel's mind was of no inferior quality, and his journal, as a candid record of the yearnings and meditations of a thoughtful, affectionate, and wounded spirit, gained a sympathy which the author had failed to obtain in his life. He also wrote studies on Erasmus, Madame de Staël, and other literary personages, and several volumes of poems. Amiel died in Geneva on the 27th of December 1881. (R. G.)

Amiens, the ancient capital of Picardy, and chief town of the department of Somme, France, situated on the river Somme, 81 miles from Paris by the Paris-Calais railway. It has also railway communication with Arras, Lille and Belgium, Tergnier and Rheims, Rouen and Normandy, Doullens, Beauvais and Crépy-en-Valois. The chief industries of the town are manufactures of cotton-velvet (value of annual production, £400,000) and Utrecht velvet (20,000 pieces, value £200,000 to £240,000 a year), cotton-spinning, wool-spinning (50,000 spindles), hemp and flax-spinning (24,000 spindles), weaving, manufactures of hosiery, carpets, machinery, chemicals, sugar, and *nouveautés*, brewing, tanning, printing, and founding. The population of the town in 1886 was 68,177; in 1896, 74,808 (commune, 88,731); in 1901, 90,758.

Ammunition. See PROPELLANTS, and ORD-NANCE.

Amoy, a town and treaty-port on the small island of Hiamen, province of Fuhkien, China. It has dry docks and an excellent anchorage. The trade in 1870 was: imports, £1,915,427; and exports, £1,440,000. In 1899 the figures were: imports, £2,180,000; and exports, £363,000. The falling off of exports is due to the decreased demand for China tea, for which Amoy was one of the chief centres. The native population is now estimated at 300,000, and the foreign residents number about 280. A large part of the trade is that carried on with the neighbouring island of Formosa, now Japanese. The province of Fuhkien is claimed by the Japanese as their particular sphere of influence.

Amphibia.—The arguments adduced by Huxley, in his article on this subject in the ninth edition of the *Encyclopædia Britannica*, for applying this name to those lung-breathing, pentadactyle vertebrates which had been first severed from the Linnæan *Amphibia* by Brongniart, under the name of *Batrachia*, have not met with universal acceptance. Although much used in text-books and anatomical works in Great Britain and in Germany, the former name has been discarded in favour of the latter by the principal authors on systematic herpetology, such as Peters, Günther, and Cope, and their lead is followed in the present article. Bearing in mind that Linnæus, in his use of the name Amphibia, was not alluding to the branchiate and pulmonate periods through which most frogs and newts pass in the course of their existence, but only wished to convey the fact that many of the constituents of the group resort to both land and water (e.g., crocodiles), it seems hard to admit that the term may be thus diverted from its original signification, especially when such a

change results in discarding the name expressly proposed by Brongniart to denote the association which has ever since been universally adopted either as an order, a subclass, or a class. Many authors who have devoted special attention to questions of nomenclature therefore think *Reptilia* and *Batrachia* the correct names of the two great classes into which the Linnæan *Amphibia* have been divided, and consider that the latter term should be reserved for the use of those who, like that great authority, the late Professor Peters, down to the time of his death in 1883, would persist in regarding reptiles and batrachians as mere sub-classes (1). However extraordinary it may appear, especially to those who bring the living forms only into focus, that opposition should still be made to Huxley's primary division of the vertebrates other than mammals into *Sauropsida* (birds and reptiles) and *Ichthyopsida* (batrachians and fishes), it is certain that recent discoveries in palæontology have reduced the gap between batrachians and reptiles to such a minimum as to cause the greatest embarrassment in the attempt to draw a satisfactory line of separation between the two; on the other hand the hiatus between fishes and batrachians remains as wide as it was at the time the article "Amphibia" was written. When we turn to the definition given in that article (*Ency. Brit.* vol. i. p. 750), we find that one of the essential characters—"two occipital condyles, the basi-occipital region of the skull either very incompletely, or not at all ossified"—may require revision, if it be true, as held by some authors, that the bone on which the occipital condyles have been found most developed, in some labyrinthodonts (2), represents a large basi-occipital bone yielding the two knobs for the articulation of the skull, whilst the skull of the batrachians of the present day has lost the basi-occipital, and the condyles are furnished by the exoccipitals. More than this, some reptiles are now known to have the occipital condyle divided, into two, and produced either by the basi-occipital (e.g., *Amphisbænidæ*, in some of which the double condyle resembles very closely that of the labyrinthodont *Bothriceps*), or by the exoccipitals (e.g., *Uroplatiidæ*). When we remember that the supposed condition of the occipital condyles was not very long ago thought sufficient to point to a possible direct descent of the mammals from the batrachians, we shall realize the full importance of the more correct information now available on this point. As a result of his researches on the anomodont reptiles and the *Stegocephalia* (3), as the extinct order that includes the well-known labyrinthodonts is now called, we have had the proposal by Seeley (4) to place the latter with the reptiles instead of with the batrachians; whilst Credner (5), basing his views on the discovery by him of various annectent forms between the *Stegocephalia* and the Rhynchocephalian reptiles, has proposed a class, *Eotetrapoda*, to include these forms, ancestors of the batrachians proper on the one hand, of the reptiles proper on the other. Yet, that the *Stegocephalia*, notwithstanding their great affinity to the reptiles, ought to be included in the batrachians as commonly understood, seems sufficiently obvious from the mere fact of their passing through a branchiate condition, i.e., undergoing metamorphosis (6). The outcome of our present knowledge points to the *Stegocephalia*, probably themselves derived from the Crossopterygian fishes (7) having yielded on the one hand the true batrachians (retrogressive series), with which they are to a certain extent connected through the *Caudata* and the *Apoda*, on the other hand the reptiles (progressive series), through the Rhynchocephalians and the Anomodonts, the latter being believed, on very suggestive evidence, to lead to the mammals (8).

The division of the class Amphibia, or Batrachia, into

four orders, as carried out by Huxley, is maintained, with, however, a change of names: *Stegocephalia*, for the assemblage of minor groups that cluster round the *Labyrinthodonta* of Owen, which name is restricted to the forms for which it was originally intended; *Peromela*, *Urodela*, *Anura*, are changed to *Apoda*, *Caudata*, *Ecaudata*, for the reason that (unless obviously misleading, which is not the case in the present instance) the first-proposed name should supersede all others for higher groups as well as for genera and species, and the latter set have the benefit of the law of priority. In the first subdivision of the batrachians into two families by Duméril in 1806 (*Zool. Anal.* pp. 90-94) these are termed "Anoures" and "Urodèles" in French, *Ecaudati* and *Caudati* in Latin. When Duméril's pupil, Oppel, in 1811 (*Ordn. Rept.* p. 72), added the Cæilians, he named the three groups *Apoda*, *Ecaudata*, and *Caudata*. The Latin form being the only one entitled to recognition in zoological nomenclature, it follows that the last-mentioned names should be adopted for the three orders into which recent batrachians are divided.

Fig. 1.—Upper view of *Archegosaurus Decheni*. (Outlines after Credner.) pm, premaxilla; n, nasal; m, maxilla; l, lacrymal; pf, prefrontal; f, frontal; j, jugal; ptf, postfrontal; p, parietal; st, supratemporal; sq, squamosal; pto, postorbital; o, occipital; pt, post-temporal; q, quadrate.

I. **STEGOCEPHALIA** (9).—Tailed, lacertiform, or serpentiform, or serpentiform batrachians, with the temporal region of the skull roofed over by postorbital, squamosal, and supratemporal plates similar to the same bones in Crossopterygian fishes, and likewise with paired bones (occipitals and post-temporals) behind the parietals and supratemporals. A parietal foramen; scales or bony scutes frequently present, especially on the ventral region, which is protected further by three large bony plates—interclavicle and clavicles, the latter in addition to cleithra.

Extinct, ranging from the Upper Devonian to the Trias. Our knowledge of Devonian forms is still extremely meagre, the only certain proof of the existence of pentadactyle vertebrates at that period resting on the footprints discovered in Pennsylvania and described by Marsh (10) as *Tinopus antiquus*. Sundry remains from Belgium, as to the identification of which doubts are still entertained, have been regarded by Lohest (11) as evidence of these batrachians in the Devonian. Over 200 species are now distinguished, from the Carboniferous of Europe and North America, the Permian of Europe, North America, and South Africa, and the Trias of Europe, America, South Africa, India, and Australia. The forms of batrachians with which we are acquainted show the vertebral column to have been evolved in the course of time from a notochordal condition with segmented centra similar to that of early bony Ganoid fishes (e.g., *Caturus*, *Eurycormus*) to biconcave centra, and finally to the socket-and-ball condition that prevails at the present day. However, owing to the evolution of the vertebral column in various directions, and to the inconstant state of things in certain annectent groups, it is not possible, it seems, to apply the vertebral characters to taxonomy with that rigidity which Cope and some other recent authors have attempted to enforce. This is particularly evident in the case of the *Stegocephalians*; and recent batrachians, tailed and tailless, show the mode of articulation of the vertebrae, whether amphicoelous, opisthocelous, or procelous, to be of but secondary systematic importance in dealing with these lowly vertebrates. The following division of the *Stegocephalians* into five sub-orders is therefore open to serious criticism; but it seems on the whole the most natural to adopt in the light of our present knowledge.

A. Rhachitomi (Figs. 1, 2), in which the spinal cord rests on the notochord, which persists uninterrupted and is surrounded by three bony elements in addition to the neural arch: a so-called pleurocentrum on each side, which appears to represent the centrum proper of reptiles and mammals, and an intercentrum or hypocentrum below, which may extend to the neural arch, and probably answers to the hypapophysis, as it is produced into

FIG. 2.—A, Dorsal vertebra. B, Caudal vertebra of *Arcegosaurus*. (Outline after Jaekel.) na, neural arch; ch, chords; pl, pleurocentrum; ic, intercentrum.

chevrons in the caudal region. Mostly large forms, of Carboniferous and Permian age, with a more or less complex infolding of the walls of the teeth. Families: ARCEGOSAURIDÆ, ERYOPIDÆ, TRIMORRHACHIDÆ, DISSORHOPIDÆ. The last is remarkable for an extraordinary endo- and exo-skeletal carapace, *Dissorhophus* being described by Cope (12) as a "batrachian armadillo."

B. Embolomeri, with the centra and intercentra equally developed discs, of which there are thus two to each neural arch; these discs perforated in the middle for the passage of the notochord. This type may be directly derived from the preceding, with which it appears to be connected by the genus *Diplospodylus*, Fam.: CRICOTIDÆ, Permian.

C. Labyrinthodonta, with simple biconcave vertebral discs, very slightly pierced by a remnant of the notochord and supporting the loosely articulated neural arch. This condition is derived from that of the *Rhachitomi*, as shown by the structure of the vertebral column in young specimens. Mostly large forms from the Trias (a few Permian), with true labyrinthic dentition. Families: LABYRINTHODONTIDÆ, ANTHRACOSAURIDÆ, DENDRERPETIDÆ, NYRANIDÆ.

D. Microsauria, nearest the reptiles, with persistent notochord completely surrounded by constricted cylinders on which the neural arch rests. Teeth hollow, with simple or only slightly folded walls. Mostly of small size and abundant in the Carboniferous and Lower Permian. Families: UROCORDYLIDÆ, LIMNERPETIDÆ, HYLO-

FIG. 3.—A, Dorsal vertebra of *Hylonomus* (side view and front view). B, Dorsal vertebra of *Branchiosaurus* (side view and front view). (After Credner.) n, neural canal; ch, chords.

NOMIDÆ, (Fig. 3) MICROBRACHIDÆ, DOLICHOSOMATIDÆ; the latter serpentiform, apodal.

E. Branchiosauria, nearest to the true batrachians; with persistent, non-constricted notochord, surrounded by barrel-shaped, bony cylinders formed by the neural arch above and a pair of intercentra below, both these elements taking an equal share in the formation of a transverse process on each

side for the support of the rib. This plan of structure, apparently evolved out of the rhachitomous type by suppression of the pleurocentra and the downward extension of the neural arch, leads to that characteristic of frogs in which, as development

shows, the vertebra is formed wholly or for the greater part by the neural arch (13). Small forms from the Upper Carboniferous and Permian formations. A single family: BRANCHIOSAURIDÆ.

II. APODA (14).—No limbs. Tail vestigial or absent. Frontal bones distinct from parietals; palatines fused with maxillaries. Male with an intermittent copulatory organ. Degraded, worm-like batrachians of still obscure affinities, inhabiting tropical Africa, South-eastern Asia, and tropical America. Thirty-three species are known. No fossils have yet been discovered. It has been attempted of late to do away with this order altogether and to make the Cæcilians merely a family of the Urodeles. This view has originated out of the very remarkable superficial resemblance between the *Ichthyophis*-larva and the *Amphiuma*. Cope (15) regarded the Apoda as the extremes of a line of degeneration from the Salamanders, with *Amphiuma* as one of the annectent forms. In the opinion of the cousins Sarasin (16), whose great work on the development of *Ichthyophis* is one of the most important recent contributions to our knowledge of the batrachians, *Amphiuma* is a sort of neotenic Cæcilian, a larval form become sexually mature while retaining the branchial respiration. If the absence of limbs and the reduction of the tail were the only characteristic of the group, there would be, of course, no objection to unite the Cæcilians with the Urodeles; but, to say nothing of the scales, present in many genera of Apodals and absent in all Caudates, which have been shown by Credner to be identical in structure with those of Stegocephalians, the Cæcilian skull presents features which are not shared by any of the tailed batrachians. G. M. Winslow (17), who has made a study of the chondrocranium of *Ichthyophis*, concludes that its condition could not have been derived from a Urodele form, but points to some more primitive ancestor. That this ancestor was nearly related to, if not one of the Stegocephalians, future discovery will in all probability show.

III. CAUDATA (18).—Tailed batrachians, with the frontals distinct from the parietals and the palatines from the maxillary. Some of the forms breathe by gills throughout their existence, and were formerly regarded as establishing a passage from the fishes to the air-breathing batrachians. They are now considered as arrested larvæ descended from the latter. One of the most startling discoveries of the decade 1890-1900 was the fact that a number of forms are devoid of both gills and lungs, and breathe merely by the skin and the buccal mucose membrane (19). Three blind cave-forms are known: one terrestrial—*Typhlotriton*, from North America, and two perennibranchiate—*Proteus* in Europe and *Typhlomolge* (Fig. 4) in North America.

FIG. 4.—*Typhlomolge rathbuni*.

This order contains about 150 species, referred to five families: HYLÆOBATRACHIDÆ, SALAMANDRIDÆ, AMPHIUMIDÆ, PROTEIDÆ, SIRENIDÆ.

Fossil remains are few in the Upper Eocene and Miocene of Europe and the Upper Cretaceous of North America. The oldest Urodele known is *Hylæobatrachus*, Dollo (20) from the Lower Wealden of Belgium. At present this order is confined to the northern hemisphere, with the exception of two *Speleperpes* from the Andes of Ecuador and Peru, and a *Plethodon* from Argentina.

IV. ECAUDATA (21).—Frogs and toads. Four limbs and no tail. Radius confluent with ulna, and tibia with fibula; tarsus (astragalus and calcaneum) elongate, forming an

additional segment in the hind limb. Caudal vertebræ fused into a urostyle or coccyx. Frontal bones confluent with parietals.

This order embraces about 1300 species, of which some 40 are fossil, divided into two sub-orders and sixteen families:—

A. Aglossa.—Eustachian tubes united into a single ostium pharyngeum; no tongue. DACTYLETRIDÆ, PIPIDÆ.

B. Phaneroglossa.—Eustachian tubes separated; tongue present. DISCOGLOSSIDÆ, PELOBATIDÆ, HEMIPHRACTIDÆ, AMPHIGNATHODONTIDÆ, HYLIDÆ, BUFONIDÆ,

DENDROPHRYNSCIDÆ, CYSTIGNATHIDÆ, DYSOCHIDÆ, GENYOPHRYNIDÆ, ENGYSTOMATIDÆ, CERATOBATRACHIDÆ, RANIDÆ, DENDROBATIDÆ.

The Phaneroglossa are divided into two groups: *Arctifera* and *Firmisternia*, representing two stages of evolution. The family characters are mainly derived from the dilatation or non-dilatation of the sacral diapophyses, and the presence of teeth in one or both jaws, or their absence. The *Discoglossidæ* are noteworthy for the presence of short ribs to some of the vertebræ, and in some other points, also, they approach the tailed batrachians; they may be safely regarded as, on the whole, the most generalized of known Ecaudata. Distinct ribs are present at an early age in the *Aglossa*, as discovered by Ridewood (22). The recent addition of a third genus of *Aglossa*, *Hymenochirus* (23) from tropical Africa, combining characters of *Pipa* and *Xenopus*, has removed every doubt as to the real affinity which connects these genera. *Hymenochirus* is further remarkable for the presence of only six distinct pieces

Fig. 5.—Vertebral column of *Hymenochirus* (ventral view).

in the vertebral column, which is thus the most abbreviated among all vertebrata (Fig. 5).

Apart from a few unsatisfactory remains from the Eocene of Wyoming, fossil tailless batrachians are only known from the Oligocene, Miocene, and Pliocene of Europe and India. These forms differ very little from those that live at the present day in the same part of the world, and some of the genera (*Discoglossus*, *Bufo*, *Oxyglossus*, *Rana*) are even identical. *Palæobatrachus* (24), of which a number of species represented by skeletons of the perfect form and of the tadpole have been described from Miocene beds in Germany, Bohemia, and France, seems to be referable to the *Pelobatidæ*; this genus has been considered as possibly one of the *Aglossa*, but the absence of ribs in the larvæ speaks against such an association.

Since the publication of the article AMPHIBIA numerous additions have been made to our knowledge of the development and nursing habits, which are extremely varied, some forms dispensing with or hurrying through the metamorphoses and hopping out of the egg in the perfect condition (25).

(G. A. B.)

Amphioxus.—Amphioxus has been briefly treated under the headings ICHTHYOLOGY, LANCELET, and VERTEBRATA in the ninth edition of this work. Such, however, is its importance in the present zoological system that a more extended notice is desirable. The theoretical interest of Amphioxus depends upon a variety of circumstances. In its manner of development from the egg, and in the constitution of its digestive, vascular, respiratory (branchial), excretory, skeletal, nervous, and muscular systems it exhibits what appears to be a primordial condition of vertebrate organization, a condition which is, in fact,

partly recapitulated in the course of the embryonic stages of craniate vertebrates. In comparative morphology it provides many illustrations of important biological principles (such, for example, as substitution and change of function of organs), and throws new light upon, or at least points the way to new ideas of the primitive relations of different organic systems in respect of their function and topography. One of the most puzzling features in its structure, and, at the same time, one of the greatest obstacles to the view that it is essentially primitive and not merely a degenerate creature, is the entire absence of the paired organs of special sense, olfactory, optic, and auditory, which are so characteristic of the higher vertebrates. Although it is true that there is a certain amount of gradation in the degree of development to which these organs have attained in the various orders, yet it is hardly sufficient to enable the imagination to bridge over the gap which separates Amphioxus from the lowest fishes in regard to this feature of organization.

Classification.—On account of the absence of anything in the nature of a skull, Amphioxus has been regarded as the type of a division, *Acrania*, in contrast with the *Craniota* which comprise all the higher Chordata. The ordinal name for the genera and species of Amphioxus is *Cephalochorda*, the term referring to the extension of the primary backbone or *notochord* to the anterior extremity of the body; the family name is *Branchiostomidae*. The amount of generic divergence exhibited by the members of this family is not great in the mass, but is of singular interest in detail. There are two principal genera—1. *Branchiostoma* Costa, having paired sexual organs (gonadic pouches); 2. *Heteropleuron* Kirkaldy, with unilateral gonads. Of these, the former includes two subgenera, *Amphioxus* (s. str.) Yarrell and *Dolichorhynchus* Willey. The species belonging to the genus *Heteropleuron* are divided among the three subgenera *Paramphioxus* Haeckel, *Epigonichthys* Peters, and *Asymmetron* Andrews. The generic characters are based upon definite modifications of form which affect the entire facies of the animals, while the specific diagnoses depend upon minor characters, such as the number of *myotomes* or muscle-segments.

Habits and Distribution.—With regard to its habits, all that need be said here is that while Amphioxus is an expert swimmer when occasion requires, yet it spends most of its time burrowing in the sand, in which, when at rest, it lies buried with head protruding and mouth wide agape. Its food consists of microscopic organisms and organic particles; these are drawn into the mouth together with currents of water induced by the action of the vibratile cilia which are abundant along special tracts on the sides and roof of the vestibule of the mouth and in the walls of the perforated pharynx ("ciliary ingestion"). Amphioxus favours a littoral habitat, and rarely if ever descends below the 50-fathom line. Species occur in all seas of the temperate, tropical, and subtropical zones. The European species, *A. lanceolatus*, is found in the Black and Mediterranean Seas, and on the coasts of France, Great Britain, and Scandinavia, while a closely allied species or sub-species, *A. caribæus*, frequents the Caribbean region from

FIG. 1. — *Epigonichthys cultellus* from below and from the left side. (Slightly altered from Kirkaldy.) *rm* and *lm*, right and left metapleur; *at*, atriopore; *an*, anus; *e*, "eyespot" at anterior end of neurochord projecting beyond the myotomes (*my*); *n*, notochord; *r go*, gonads of right side only showing through by transparency; *go 20*, the last gonad; *dfr*, dorsal fin with fin-chambers and fin-rays; *vc*, ventral fin-chambers.

cultellus (Fig. 1) inhabits Torres Strait, and has also been found at Ternate. *Asymmetron lucayanum* is the Bahaman representative of the family, with a sub-species, *A. caudatum*, in the South Pacific from New Guinea to the Loyalty Islands. The Peruvian species, *Branchiostoma elongatum*, with nearly 80 myotomes, cannot at present be assigned to its proper sub-genus.

External Form.—The following description, unless otherwise stated, refers to *A. lanceolatus*, which has been already figured in side view, in section, and in dissection in the article VERTEBRATA (*Ency. Brit.* vol. xxiv.). Amphioxus is a small fish-like creature attaining a maximum length of about 3 inches, semi-transparent in appearance, showing iridescent play of colour. The body is narrow, laterally compressed and pointed at both ends. The main musculature can be seen through the thin skin to be divided into about sixty pairs of muscle-segments (*myotomes*) by means of comma-shaped dissepiments, the *myocommas*, which stretch between the skin and the central skeletal axis of the body. These myotomes enable it to swim rapidly with characteristic serpentine undulations of the body, the movements being effected by the alternate contraction and relaxation of the longitudinal muscles on both sides. Apparently correlated with this peculiar locomotion is the anatomical fact of the alternation of the myotomes on the two sides. Symmetrical at their first appearance in the embryo, the *somites* (from which the myotomes are derived) early undergo a certain distortion, the effect of which is to carry the somites of the left side forwards through the length of one half-segment. For example, the twenty-seventh myotome of the left side is placed opposite to the twenty-sixth myocomma of the right side. The back of the body is occupied by a crest, called the *dorsal fin*, consisting of a hollow ridge, the cavity of which is divided into about 250 compartments or *fin-chambers*, into each of which, with the exception of those near the anterior and posterior ends of the body, projects a stout pillar composed of characteristic laminar tissue, the *fin-ray*.

The dorsal crest is continued round both extremities, becoming expanded to form the *rostral fin* in front and the *caudal fin* behind. Even in external view, careful inspection will show that the body is divisible into four regions, namely, cephalic, atrial, abdominal, and caudal. The *cephalic region* includes the rostrum or præoral lobe and the mouth. As already stated, the notochord extends beyond the mouth to the tip of the rostrum. The mouth consists of two portions, an outer *vestibule* and an inner *apertura oris*; the latter is surrounded by a sphincter muscle, which forms the so-called *velum*. The vestibule of the mouth is the space bounded by the *oral hood*; this arises by secondary down-growth of lip-like folds over the true oral aperture, and is provided with a fringe of *tentacular cirri*, each of which is supported by a solid skeletal axis. The oral hood with its cirri has a special nerve-supply and musculature by which the cirri can be either spread out, or bent inwards so that those of one side may interdigitate with those of the other, thus completely closing the entrance to the mouth. The velum is also provided with a circlet of twelve tentacles (in some species sixteen) which hang backwards into the pharynx; these are the *velar tentacles*. The *atrial region* extends from the mouth over about two-thirds of the length of the body, terminating at a large median ventral aperture, the *atriopore*; this is the excurrent orifice for the respiratory current of water and also serves for the evacuation of the generative products. This region is really the *branchiogenital region*, although the fact is not apparent in external view. The ventral side of the body in the atrial region is broad and convex, so that the body presents the appearance

FIG. 2.—*Amphioxus lanceolatus* laid open ventrally. (After Rathke, slightly altered.) *m*, mouth appearing as an elongated slit when relaxed (as in the lamprey); *p*, perforated pharynx; *e*, endostyle; *g*, gonads; *l*, liver; *at*, level of atriopore; *i*, intestine; *an*, anus. In this species the atrium is produced as an asymmetrical blind pouch behind the atriopore as far as the anus. In the genus, *Branchiostoma* the metapleural folds terminate symmetrically shortly behind the atriopore, but in *Heteropleuron* the right metapleur passes uninterruptedly into the median crest of the *ventral fin* (Fig. 1). In this connexion it may also be mentioned that in all cases the right half of the oral hood is directly continuous with the rostral fin (Fig. 2).

Chesapeake to La Plata. *A. californiensis* occurs on the coast of California, and *A. belcheri* extends its area of distribution from Queensland through Singapore to Japan. A recently described species, *Dolichorhynchus indicus*, characterized by the great length of the præoral lobe or snout, has been dredged in the Indian Ocean. *Paramphioxus bassanum* occurs on the coast of Australia from Port Phillip to Port Jackson; *P. cingalensis* at Ceylon. *Epigonichthys*

The *abdominal region* comprises a short stretch of body between atriopore and anus, the termination of the alimentary canal. It is characterized by the presence of a special development of the *lophoderm* or median fin-system, namely, the *ventral fin*, which is composed of two portions, a lower keel-like portion, which underlies an upper chambered portion, each chamber containing typically a pair of gelatinous fin-rays. Finally, the *caudal region* comprises the post-anal division of the trunk. The keel of the ventral fin is continued past the anus into the expanded caudal fin, and so it happens that the anal opening is displaced from the middle line to the left side of the fin. In *Asymmetron* the caudal region is remarkable for the curious elongation of the notochord, which is produced far beyond the last of the myotomes.

Alimentary, Respiratory, and Excretory Systems.—Although the function of the two latter systems of organs is the purification of the blood, they are not usually considered together, and it is therefore the more remarkable that their close association in *Amphioxus* renders it necessary to treat them in common. The *alimentary canal* is a perfectly straight tube lined throughout by ciliated epithelium. As food particles pass in through the mouth they become enveloped in a slimy substance (secreted by the *endostyle*) and conveyed down the gut by the action of the vibratile cilia as a continuous food-ropes, the peristaltic movements of the gut-wall being very feeble. The first part of the alimentary canal consists of the *pharynx* or *branchial sac*, the side walls of which are perforated by upwards of sixty pairs of elongated slits, the *gill-clefts*. Each primary gill-cleft becomes divided into two by a *tongue-bar* which grows down secondarily from the upper wall of the cleft and fuses with the ventral wall. New clefts continue to form at the posterior end of the pharynx during the adult life of the animal. The gill-clefts open directly from the cavity of the pharynx into that of the *atrium* and so give egress to the respiratory current which enters the mouth with the food (Fig. 2). The atrium or atrial chamber is a peripharyngeal cavity of secondary origin effecting the enclosure of the gill-clefts, which in the larva opened directly to the exterior. The atrium is thus analogous to the opercular cavity of fishes and tadpoles, and, as stated above, remains in communication with the exterior by means of the atriopore. The primary and secondary bars which separate and divide the successive gill-clefts from one another are traversed by blood-vessels which run from a simple tubular contractile ventral branchial vessel along the bars into a dorsal aorta. The ventral branchial vessel lies below the *hypobranchial groove* or *endostyle*, and is the representative of a heart. As water for respiration streams through the clefts, gaseous interchange takes place between the circulating colourless blood and the percolating water. The pharynx projects freely into the atrium; it is surrounded at the sides and below by the continuous atrial cavity, but dorsally it is held in position in two ways. Firstly, its dorsal wall (which is grooved to form the *hyperpharyngeal groove*) is closely adherent to the sheath of the notochord; and secondly, the pharynx is attached through the intermediation of the primary bars. These are suspended to the muscular body-wall by a double membrane, called the *ligamentum denticulatum*, which forms at once the roof of the atrial chamber and the floor of a persistent portion of the original body-cavity or *coelom* (the *dorsal coelomic canal* on each side of the pharynx). The *ligamentum denticulatum* is thus lined on one side by the eplastic *atrial epithelium*, and on the other by mesoblastic *coelomic epithelium*. Now this ligament is inserted into the primary bars some distance below the upper limits of the gill-clefts, and it therefore follows that, corresponding with each tongue-bar, the atrial cavity is produced upwards beyond the insertion of the ligament into a series of bags or pockets, which may be called the *atrial pouches*. At the top of each of these pouches there is a minute orifice, the aperture of a small tubule lying above each pouch in the dorsal coelom. These tubules are the excretory tubules or *nephridia*. They communicate with the coelom by several openings or *nephrostomes*, and with the atrium by a single opening in each case, the *nephridiopore*. It is important to emphasize the fact that in *Amphioxus* the excretory tubules are coextensive with the gill-clefts. The perforated pharynx terminates some distance in front of the atriopore. At the level of its posterior end a pair of funnel-shaped pouches of the atrium are produced forwards into the dorsal coelom. These are the *atrio-coelomic funnels* or *brown funnels*, so called on account of the characteristic pigmentation of their walls. There are reasons for supposing that these funnels are vestiges of an ancient excretory system, which has given way by substitution to the excretory tubules described above. In the same region of the body, namely, close behind the pharynx, a large diverticulum is given off from the ventral side of the gut. This is the *hepatic caecum* (Fig. 2, l), which is quite median at its first origin, but, as it grows in length, comes to lie against the right wall of the pharynx. Although within the atrial cavity, it is separated from the latter by a narrow coelomic space, bounded towards the atrium by coelomic and

atrial epithelium. No food passes into the hepatic caecum, which has been definitely shown on embryological and physiological grounds to be the simplest persistent form of the vertebrate liver.

Nervous System.—As has been already indicated, a solid sub-cylindrical elastic rod, the *notochord*, surrounded by a sheath of laminar connective tissue, the *chordal sheath*, lies above the alimentary canal in contact with its dorsal wall, and extends beyond it both in front and behind to the obtusely pointed extremities of the body. This notochord represents the persistent primordial skeletal axis which, in the higher Craniota (though not so in the lower), gives way by substitution to the segmented vertebral column. Immediately above the notochord there lies another sub-cylindrical chord, also surrounded by a sheath of connective tissue. This chord is neither elastic nor solid, but consists of nerve tissue, fibres, and ganglion cells, surrounding a small central canal. For the sake of uniformity in nomenclature this nerve chord may be called the *neurochord*. It is the central nervous system, and contains within itself the elements of the brain and spinal marrow of higher forms. The neurochord tapers towards its posterior end, where it is coextensive with the notochord, but ends abruptly in front, some distance behind the tip of the snout. The neurochord attains its greatest thickness not at its anterior end but some way behind this region; but the central canal dilates at the anterior extremity to form a thin-walled *cerebral vesicle*, in the front wall of which there is an aggregation of dark pigment cells constituting an *eye-spot*, visible through the transparent skin (Fig. 1). There are two pairs of specialized *cerebral nerves* innervating the praecral lobe, and provided with peripheral ganglia placed near the termination of the smaller branches. Corresponding with each pair of myotomes, and subject to the same alternation, two pairs of *spinal nerves* arise from the neurochord, namely, a right and left pair of compact dorsal sensory roots without ganglionic enlargement, and a right and left pair of ventral motor roots composed of loose fibres issuing separately from the neurochord and passing directly to their termination on the muscle-plates of the myotomes. The first dorsal spinal nerve coincides in position with the myocomma which separates the first myotome from the second on each side, and thereafter the successive dorsal roots pass through the substance of the myocommata on their way to the skin; they are therefore *septal* or *intersegmental* in position. The ventral roots, on the contrary, are *myal* or *segmental* in position.

In addition to the cerebral eye-spot there are large numbers of minute black pigmented bodies beside and below the central canal of the neurochord, commencing from the level of the third myotome. It has been determined that these bodies are of the nature of eyes (*Becheraugen*, Hesse), each consisting of two cells, a cup-shaped *pigment cell* and a triangular *retinal cell*. These may be called the *spinal eyes*, and it is said that they are disposed in such a way as to receive illumination preferentially from the right side, although this fact has no relation with the side upon which *Amphioxus* may lie upon the sand. When kept in captivity the animal often lies upon one side on the surface of the sand, but on either side indifferently. Over the cerebral eye there is a small orifice placed to the left of the base of the cephalic fin, leading into a pit which extends from the surface of the body to the surface of the cerebral vesicle; this is known as Kölliker's *olfactory pit*.

Reproductive System.—The sexes are separate, and the male or female gonads, which are exactly similar in outward appearance, occur as a series of gonadic pouches projecting into the atrial cavity at the base of the myotomes (Fig. 2). At the breeding season the walls of the pouches burst and the sexual elements pass into the atrium, whence they are discharged through the atriopore into the water, where fertilization takes place.

Development.—The development of *Amphioxus* possesses many

FIG. 3.—Diagram of embryo of *Amphioxus* seen from above in optical section. (Adapted from Hatschek.) *pe*, prechordal head-cavity of embryo; *cc*, collar-cavity (first somite); *my*, mesodermic somites (myocoelomic or archenteric pouches); *ch*, notochord with the neural tube (neurochord) lying upon it; *np*, anterior neuropore *na*, position of posterior naurenteric canal.

features of interest, and cannot fail to retain its importance as an introduction to the study of embryology. The four principal phases in the development are: (1) Blastula, (2) Gastrula, (3) Flagellate Embryo, (4) Larva. The segmentation or cleavage of the ovum which follows upon fertilization terminates in the achievement of the blastula form, a minute sphere of cells surrounding a central cavity. Then follows the phenomenon of gastrulation, by which one-half of the blastula is invaginated into the other, so as to obliterate the segmentation cavity. The embryo now consists of two layers of cells, *epiblast* and *hypoblast*, surrounding a cavity, the *archenteron*, which opens to the exterior by the orifice of invagination or *blastopore*. One important fact should be noted with regard to the *gastrula*, in which it seems to differ from the gastrulae of invertebrata. After invagination is completed, the embryo begins to elongate, the blastopore becomes narrower, and the dorsal wall of the gastrula loses its convexity and becomes flattened to form the *dorsal plate*, the outer layer of which is the primordium of the neurochord, and the inner layer the primordium of the notochord. While still within the egg-membrane the epiblastic cells become flagellated, and the gastrula rotates within the membrane. About the eighth hour after commencement of development the membrane ruptures and the oval embryo escapes, swimming by means of its flagella at the surface of the sea for another twenty-four hours, during which the principal organs are laid down, although the mouth

curiously asymmetrical, as many as fourteen gill-clefts appearing in an unpaired series on the right side, while the mouth is a large orifice on the left side, the anus being median. The adult form is achieved by metamorphosis, which cannot be further described here. One point must not be omitted, namely, the homogeneity of the *endostyle* of *A.* and the *thyroid gland* of Craniota.

FIG. 4.—Anterior region of two pelagic larvæ of *A. lanceolatus* obtained by the tow-net in 8-10 fathoms, showing the asymmetry of the large lateral sinistral mouth with its ciliated margin *cm* and the dextral series of simple primary gill-slits (*1ps-14ps*). The larvæ swim normally like the adult or suspend themselves by their flagella (not shown in the figures) vertically in mid-water. There is nothing in their mode of life which will afford an explanation of the asymmetry which is a developmental phenomenon. Lettering of upper figure.—*anp*, anterior neural pore; *bc*, rudiment of buccal skeleton; *c*, cilium; *cb*, ciliated band; *cc*, ciliated groove; *cm*, cilia at margin of mouth; *gl*, external opening of club-shaped gland; *Hn*, Hatschek's nephridium; *lm*, left metapleur; *n*, notochord; *pp*, præoral pit; *ps*, primary gill-slits, 1, 5, and 13; *rm*, right metapleur showing through. Lettering of lower figure.—*a*, atrium; *al*, alimentary canal; *bv*, blood vessel; *cy*, cerebral vesicle; *df*, dorsal section of myocoel (=fin-spaces); *e*, "eye-spot"; *end*, endostyle; *gl*, club-shaped gland; *lm*, edge of left metapleur; *m*, lower edge of mouth; *n*, notochord; *nt*, neural tube; *ps*, primary gill-slits, 1, 9, and 14; *rc*, renal cells on strial floor; *rm*, edge of right metapleur; *so*, sense organ opening into præoral pit; *ss*, thickenings, the rudiments of the row of secondary gill-slits.

does not open until the close of this period. The primordium of the neurochord (neural or medullary plate) referred to above becomes closed in from the surface by the overgrowth of surrounding epiblast, and its edges also bend up, meet, and finally fuse to form a tube, the medullary or neural tube. An important fact to note is that the blastopore is included in this overgrowth of epiblast, so that the neural tube remains for some time in open communication with the archenteron by means of a posterior *neurenteric canal*. It is still longer before the neural tube completes its closure in front, exhibiting a small orifice at the surface, the anterior *neuropore*. It is thus possible that the neurenteric canal is due to the conjunction of a posterior neuropore with the blastopore, i.e., it is a complex and not a simple structure. Paired archenteric pouches meanwhile appear at the sides of the axial notochordal tract, the *mesoblastic somites*. The first of these differs in several respects from those which succeed, and has been called the *collar cavity* (MacBride). In front of the latter there remains a portion of the archenteron, which becomes constricted off as the *head cavity*. This becomes divided into two, the right half forming the cavity of the rostrum, while the left acquires an opening to the exterior, and forms the *præoral pit* of the larva, which subsequently gives rise to special ciliated tracts in the vestibule of the mouth mentioned above. The larval period commences at about the thirty-sixth hour with the perforation of the mouth, first gill-cleft, and anus. The larva is

Ampthill, Odo William Leopold Russell,
1st BARON (1829-1884), British diplomatist and ambassador, was born in Florence on the 20th of February 1829. He was the son of Major-General Lord George William Russell, by Elizabeth Ann, niece of the marquis of Hastings, who was governor-general during the final struggle with the Mahrattas. His education, like that of his two brothers—Hastings, who became eventually ninth duke of Bedford, and Arthur, who sat for a generation in the House of Commons as member for Tavistock—was carried on entirely at home, under the general direction of his mother, whose beauty was celebrated by Byron in *Beppo*. Lady William Russell was as strong-willed as she was beautiful, and certainly deserved to be described as she was by Disraeli, who said in conversation, "I think she is the most fortunate woman in England, for she has the three nicest sons." If it had not been for her strong will it is as likely as not that all the three would have gone through the usual mill of a public school, and have lost half their very peculiar charm. In March 1849 Odo was appointed by Lord Malmesbury attaché at Vienna. From 1850 to 1852 he was temporarily employed in the Foreign Office, whence he passed to Paris. He remained there, however, only about two months, when he was transferred to Vienna. In 1853 he became second paid attaché at Paris, and in August 1854 he was transferred as first paid attaché to Constantinople, where he served under Lord Stratford de Redcliffe. He had charge of the embassy during his chief's two visits to the Crimea in 1855, but left the east to work under Lord Napier at Washington in 1857. In the following year he became secretary of legation at Florence, but was detached from that place to reside in Rome, where he remained for twelve years, till August 1870. During all that period he was the real though unofficial representative of England at the Vatican, and his consummate tact enabled him to do all, and more than all, that an ordinary man could have done in a stronger position. A reference, however, to his evidence before a committee of the House of Commons in 1871 will make it clear to any unprejudiced reader that

those were right who, during the early 'fifties, urged so strongly the importance of having a duly accredited agent at the Papal Court. The line taken by him during the Vatican Council has been criticized, but no fault can justly be found with it. Abreast as he was of the best thought of his time—the brother of Arthur Russell, who, more perhaps than any other man, was its most ideal representative in London society—he sympathized strongly with the views of those who laboured to prevent the extreme partisans of papal infallibility from having everything their own way. But in his capacity of clear-headed observer, whose business it was to reflect the actual truth upon the mind of his Government, he was obliged to make it quite clear that they had no chance whatever, and in conversing with those whose opinions were quite unlike his own, such as Cardinal Manning, he seems to have shown that he had no illusions about the result of the long debate. In 1868 Odo Russell married Lady Emily Theresa Villiers, the daughter of Lord Clarendon. In 1870 he was appointed assistant under-secretary at the Foreign Office, and in November of that year was sent on a special mission to the headquarters of the German army, where he remained till 1871. A little later in the same year he received the well-deserved reward of his labours by being made ambassador at Berlin.

During the months he passed at the Foreign Office he was examined before the committee of the House of Commons, already alluded to, and had an opportunity of stating very distinctly in public some of his views with regard to his profession. It was before the same committee that he said that "if you could only organize diplomacy properly, you would create a body of men who might influence the destinies of mankind and ensure the peace of the world." In these words we have the key to the thought and habitual action of one of the best and wisest public servants of the time. If more people could be converted to his views, the diplomatic service sufficiently increased, the means of getting adequate information from abroad improved, and that information properly digested, the cost of some regiments and not a few iron-clads might be saved.

Lord Ampthill remained at Berlin, with only brief intervals of absence, from 16th October 1871 till his death at Potsdam on the 25th August 1884. He was third plenipotentiary at the Berlin Congress, and is generally credited with having prevented, by his tact and good sense, the British prime minister from making a speech in French, which he knew very imperfectly and pronounced abominably. In 1874 Odo Russell received a patent of precedence raising him to the rank of a duke's son, and after the Congress of Berlin he was offered a peerage by the Conservative Government. This he naturally declined, but accepted the honour when it was offered by the Liberals. He became a privy councillor in 1872 and was made a G.C.B. somewhat later. At the conference about the Greek frontier, which followed the Congress of Berlin, he was the only British representative. During all his long sojourn in the Prussian capital, he did everything that in him lay to bring about close and friendly relations between Great Britain and Germany. He kept on the best of terms with Bismarck, carefully avoiding everything that could give any cause of offence to that most jealous and most unscrupulous minister, whom he, however, did not hesitate to withstand when his unscrupulousness went the length of deliberately attempting to deceive. What might have happened if Lord Ampthill's life had been prolonged, and the Emperor Frederick had come to the throne at about the period of life at which it would have been natural for him to do so, in the first half of the 'seventies, it is impossible to say. The death in 1888 of the Emperor

Frederick was, as has been truly said, "Not the death of a man but of a generation." (M. G. D.)

Amraoti, or Umrawattee, a town and district of India, in Berar or the Haidarabad Assigned Districts, under British administration. The town is 1222 feet above the sea; the railway station is 6 miles from Badnera junction on the Great Indian Peninsula line. Population (1881), 23,550; (1891), 28,946, excluding 4709 in the civil station. Amraoti raw cotton is quoted on the Liverpool Exchange. There are 11 cotton presses with an out-turn of 70,000 bales; and a mill at Badnera, with 248 looms and 18,900 spindles, employing 1186 hands, which, in 1897-98, produced 5796 bales of twist and yarn, and 2442 bales of cloth. There are two high schools, with 354 pupils; and a school for European boys and girls, maintained by a Roman Catholic mission. The town has four printing-presses, one issuing a vernacular newspaper.

The district of AMRAOTI has an area of 2759 square miles; population (1881), 575,328; (1891), 655,645; (1901), 630,245, showing a decrease of 4 per cent. The land revenue and rates in 1897-98 were Rs.17,01,357, the incidence of assessment being R.1:1:4 per acre; the cultivated area was 1,414,361 acres, of which 8745 are irrigated from wells; the number of police was 623; the number of boys at school in 1896-97 was 14,065, being 27.5 per cent. of the male population of school-going age; the registered death-rate in 1897 was 60.5 per thousand. The district is crossed by the main line of the Great Indian Peninsula railway. In 1899-1900 it suffered severely from drought.

Amravati, a village of British India, in the Kistna district of the Madras Presidency. It is situated in 16° 34' N. lat. and 80° 24' E. long., on the right bank of the river Kistna, near the head of its delta. Here are, or rather were, the ruins of the finest Buddhist monument in India. It was a *stupa*, or "tope," built to enshrine a relic of Gautama Buddha. It is enthusiastically described by Hwen Thsang, the Chinese pilgrim, who visited it in 639. In the beginning of the 19th century elaborate excavations and drawings were made by Colin Mackenzie. The sculptures subsequently carried off by Sir Walter Elliot now line the great staircase of the British Museum, and are figured in Fergusson's *Tree and Serpent Worship* (1868). Further researches were conducted on behalf of the Government in 1877 and 1882, and the best of the remaining sculptures were taken to Madras. A handsome memoir by Dr James Burgess was published in 1887, as one of the volumes of the Archaeological Survey of Southern India.

Amritsar (UMRITSUR), a city and district of British India, in the Lahore division of the Punjab. It has a station on the North-western railway 32 miles east of Lahore. Population (1881), 151,896; (1891), 136,766; (1901), 162,548, showing an increase of 19 per cent. Municipal income (1897-98), Rs.4,42,372; death-rate (1897), 36 per thousand. A Sikh college for university education was opened in 1897. The other public buildings include two churches, a town hall, and a hospital. There are also a municipal college; 5 high schools for boys; 3 secondary schools for girls; 17 printing presses, issuing 10 newspapers and periodicals; Hindu, Sikh, and Mahomedan literary institutions.

The area of the district of AMRITSAR is 1601 square miles; population (1881), 893,266; (1891), 992,697, showing an increase of 11 per cent., and an average density of 620 persons per square mile; (1901), 1,023,902, showing an increase of 3 per cent. The land revenue and rates in 1897-98 amounted to Rs.12,44,644, the incidence

of assessment being R.1: 5: 0 per acre; the cultivated area was 772,724 acres, of which 543,068 were irrigated, including 247,465 from government canals; the number of police was 852; the number of schools in 1896-97 was 395, attended by 15,376 boys, being 17.4 per cent. of the boys of school-going age; the death-rate in 1897 was 28 per thousand. The principal crops are wheat, pulse, maize, millet, with some cotton and sugar-cane. There are two factories for ginning and pressing cotton.

Amroha, a town of British India, in the Moradabad district of the North-west Provinces, is situated in 28° 54' N. lat. and 78° 31' E. long. It contains the tomb of Shaikh Saddu, and has been for many centuries a Mahomedan centre. It has a high school. In 1897-98 the municipal income was Rs.25,687. Population (1891), 35,230.

Amsterdam, the capital and one of the two chief commercial centres of the Netherlands, in the province of North Holland, on the Y inlet of the Zuyder Zee; connected by the Ymuiden Canal with the North Sea. The mouey market is of importance, and is the headquarters of companies formed to promote the cultivation of colonial produce. A central station has been erected (1888), a new theatre (1894), a new post office (1898), a music hall, a new exchange (1901), and an abattoir. To scientific and artistic institutions have been added a school of navigation (1879), a school of engineering (1879), a school for teachers (1878), a school of industrial art; the "Quellinus" (1880), a university (1877), which took the place of the Athenæum, a free university (1883), the State Museum (Ryksmuseum, 1876-85), in which are collected, from various other museums, pictures, drawings, prints, sculpture, and casts, and the Museum Suesso Lopez, for modern paintings (1895). The progress of navigation and commerce has been promoted by the construction of a canal to the North Sea (1876), with a depth of 30 to 33 feet; the Commercial or *Handels* dock; the railway, wood, and petroleum (1880-90) docks; the Merwede Canal, connecting the town with the great rivers (1893), and the new Entrepôt dock (1900). The tonnage of ships entering and clearing the port in 1870 was 808,042 tons (metric), which in 1899 had risen to 4,310,000 tons (16.6 per cent. of that of the whole kingdom). In 1899, 9988 ships of 15,680,000 tons passed through the North Sea Canal. In 1899, 2029 vessels entered with the following imports:—163 ship loads of timber, 142 of ore, 177 of coal and coke, 312 of piece goods, 34 of rice and other grain, 25 of petroleum, 4 of linseed, and the remaining 1172 of ballast and miscellaneous goods. Of late years Sumatra tobacco has ranked first among the exports of colonial produce; but tea, cocoa, and Peruvian bark (*cinchona*) are also important. The supply of tea for the Amsterdam market, which in 1888 amounted to 5,002,000 lb, had risen in 1897 to 10,738,225 lb; the supply of cinchona in 1889, 171,207 lb, had risen in 1897 to 580,722 lb. The value of Sumatra tobacco imported in 1865 was £3333; in 1896, £2,687,500. Since 1874 railways have been constructed connecting Amsterdam with Belgium (*viâ* Utrecht, Bois-le-Duc, and Maestricht) and with Prussia (*viâ* Hilversum and Zutphen). Regular steamers maintain communication with sixty-one places in the Netherlands. The tonnage of this inland navigation, carried in 80,000 vessels, amounted in 1899 to 4,310,000 cubic metres (the register ton is equal to 2.83 cubic metres). To the industries have been added of late years shipbuilding and the manufacture of machinery and stearine candles. The population in 1874 was 285,000; in 1890, 408,061; in 1900, increased by that of Neuner Amstel (annexed in 1896; population, 25,000), 523,557,

about 100,000 of whom are Roman Catholics and about 50,000 Jews.

See TER GOUW. *Amstelodamiana*. Amsterdam, 1873-74.—SEQUERA. *Amsterdam, Guide descriptive, historique et topographique*. Amsterdam, 1877.—TER GOUW. *Geschiedenis van Amsterdam*. Amsterdam, 1886.—KALFF. *Oud en Nieuw Amsterdam*. Amsterdam, 1880. (C. M. K.)

Amsterdam, a city of Montgomery county, New York, U.S.A., situated in 42° 57' N. lat. and 74° 11' W. long., on the north bank of Mohawk river, at an altitude of 277 feet. Its site is hilly and the plan is irregular. It is divided into seven wards. Two railways enter it, the New York Central and Hudson River, and the West Shore. It has an excellent water supply and good drainage. The population in 1880 was 9466, in 1890 it was 17,336, and in 1900 it was 20,929.

Amu-daria, a great river of Central Asia, tributary of Lake Aral (see OXUS), and also the name of a separate administrative division (*Amu-dariñskiy Otdyel*) of the Syr-daria province of Russian Turkestan. (See TURK-ESTAN, SYR-DARIA, and ARAL-CASPIAN REGION.)

Amur, an extensive province of Siberia, Russia in Asia, on the left bank of the Amur river, which was conceded to Russia by China by the treaties of 1857 and 1858. It includes the basins of the Oldoi, Zeya, and Bureya, left bank tributaries of the Amur, and has the provinces of Transbaikalia in the W., Yakutsk in the N., Maritime in the E., and Manchuria in the S.W. and S. Area, 172,848 sq. miles. Immense districts are quite uninhabited. All its north-western part is occupied by the High plateau, bordered by the Great Khingan border range, whose exact position in the region is not yet definitely settled. Next comes a belt of fertile high plains, inhabited mainly by Nonconformist emigrants from Russia, and limited on the east by the Little Khingan, or Dousse-alin, a picturesque well-wooded range, which stretches in a north-easterly direction from Kirin across Manchuria, is pierced by the Amur, and continues on its left bank, separating the Bureya from Amgun. To the east of it stretches in the same direction a belt of marshy lowlands, which includes also farther south the lower course of the Sungari. Frequent inundations, resulting from torrential rains occasioned by the monsoons, present great difficulties to the development of the belt. In the ranges which rise above the surface of the high plateau in the north-west, in the vicinity of the Stanovoi watershed, gold-mines of great richness are worked. Gold was also found in the fabulously rich mines of the Zheltuga (Manchuria) where a sort of free republic of Russian and Chinese miners was formed in 1880-82. Coal of inferior quality is known to exist on the Oldoi, Zeya, and Bureya. The Russians are represented by the Amur Cossacks, whose villages are situated at about 17 to 20 miles from each other along the whole course of the river (Albazin, Kumara, Ekaterino-Nikolskaya, and Mikhailo-Semenovskaya are the chief ones); by peasant immigrants, chiefly Nonconformists, who are the wealthiest part of the population; and by a floating population of workers in the mines. Some Chinese have remained in the province, and consider themselves under Chinese rule; Tungus (Orochons), Manegres, and Golds lead a nomadic life along the rivers, living by hunting and fishing. Steamers ply regularly along the Amur for 6½ months, from Khabarovsk to Sryetensk, on the Shilka (terminus of the Trans-Siberian Railway); but only light steamers having from 2 to 3 feet draught can navigate the upper Amur and Shilka. In the winter the frozen river is the usual highway. Rough roads and bridle-paths only are found in the interior. The great engineering difficulties in building a

railway along the Amur induced the Russian Government to obtain from China permission to build a railway through Manchuria. For the navigation on the Amur there are now 112 steamers of 29,300 horse-power, and 152 barges of 37,000 tons. The Amur province has a continental climate, the yearly average at Blagovyeschensk (50° N. lat.) being 30° Fahr. (January -17°, July 70°). It experiences the influence of the monsoons, and has mostly cold north-west winds from October to March, while in July and August it receives torrential rains, resulting in a sudden and very considerable rise of water in the Amur and all its r.b. tributaries. The chief and in fact the only town of the province is Blagovyeschensk, but the chief centre of the administration of the Amur region is now Khabarovsk. The settled population in 1897 was 118,570 (51,975 women), of whom 31,515 lived in towns. (P. A. K.)

Anaconda, a city of Montana, U.S.A., the capital of Deer Lodge county, situated in the mountains on the west side of Deer Lodge Valley, in the south-western part of the state. It is entered by the Montana Central, a branch of the Great Northern, and the Butte, Anaconda and Pacific railways. Its chief industry is the smelting of copper ores, obtained from mines in the neighbourhood. The population in 1890 was 3975, and in 1900 it was 9453.

Anam, OF ANNAM. See COCHIN CHINA.

Anamalai Hills, a range of mountains in Southern India, in the Coimbatore district of Madras, lying between 10° 13' and 10° 31' N. lat., and between 76° 52' and 77° 23' E. long., forming a portion of the Western Ghats, after this range has been broken by the Palghat Pass, south of the Nilgiris. They really consist of a forest-clad and grassy tableland, with summits rising above 8000 feet. Their geological formation is metamorphic gneiss, veined with felspar and quartz, and interspersed with reddish porphyrite. The lower slopes yield valuable teak and other timber; and some land has been taken up for coffee-planting. The only inhabitants are a few wild tribes, who live by hunting and collecting jungle produce.

Ananieff, a district town of Russia, government of Kherson, on Tiligul river, 118 miles N.W. of Odessa, 12 miles from Zherebkovo, a station of the South-Western railway. It has trade in corn and cattle. It was annexed to Russia in 1792. Population (1897), 16,713—Russians, Jews, and Moldavians.

Anantapur, a town and district of India, in the Madras presidency, situated in 14° 41' N. lat. and 77° 39' E. long. It has a station on the Madras railway, 62 miles south-east from Bellary. Population (1891), 6994. The municipal income in 1897-98 was Rs.20,410. There is a municipal high school.

The district of ANANTAPUR was constituted in 1882 out of the unwieldy district of Bellary. It has an area of 5725 square miles, and its population in 1891 was 708,549, being 134 persons per square mile; in 1901, 788,896, showing an increase of 8 per cent. The land revenue and rates were Rs.9,63,538, the incidence of assessment being R.0:12:5 per acre; the number of police was 702. In 1897-98, out of a total cultivated area of 1,428,404 acres, 169,655 were irrigated, including 34,723 from government canals; the principal crops are millet, rice, other food grains, pulse, oil-seeds, and cotton. There are three steam factories for pressing cotton. Two railways traverse the district. The number of schools in 1896-97 was 577, with 11,636 pupils; the proportion of boys at school to the population of school-going age being 19.5

per cent., and the proportion of girls 2 per cent. The registered death-rate in 1897 was 26.9 per thousand.

Anarchism, a theory of politics, according to which all forms of organized government, except the free commune, are objectionable, since the individual should be a law to himself; and a theory of economics, according to which land and capital ought to be the common property of society. There is also a propaganda of revolution by violence. The principal writers who treat of the theory of anarchy in its different aspects are Proudhon, Elisée Réclus, Herbert Spencer, Kropotkin, and Bakounine. In America, Mr Benjamin R. Tucker has published since 1882 a journal named *Liberty*, which is devoted to philosophical anarchism. In the congress of the International Working People's Association, at the Hague, September 1872, the followers of Bakounine separated themselves from those of Karl Marx. This was the definitive beginning of the anarchist propaganda. The Bakounine party organized the "Fédération Jurassienne," and established a paper at Geneva, *L'Avant Garde*. This journal was, in 1878, succeeded by *La Révolte*, founded by Réclus and Kropotkin. Revolutionary organizations of working men were also formed in France, Spain, Italy, Switzerland, Belgium, Germany, England, and the United States. Between 1882 and 1886, in France, Prince Kropotkin, Louise Michel, and others were imprisoned, and their journal suppressed. In England, Most, one of the German anarchist leaders, founded *Die Freiheit*, and, for defending in it the assassination of Alexander II. at St Petersburg, was sentenced to eighteen months' imprisonment with hard labour. After this he moved to the United States, and re-established his paper there in New York, in May 1886. During this period there were several anarchist congresses in the United States. In one at Albany, in 1878, the revolutionary element, led by Justus Schwab, broke away from the others; at Allegheny City, in 1879, again there was a rupture between the peaceful and the revolutionary sections. *The Voice of the People* at St Louis, the *Arbeiter Zeitung* at Chicago, and the *Anarchist* at Boston, were the organs of the revolutionary element. In 1883, at Pittsburg, a congress of twenty-eight delegates, representing twenty-two towns, drew up an address to the working men of America. The programme it proposed was as follows:—

First, Destruction of the existing class rule by all means, i.e. energetic, relentless, revolutionary, and international action.

Second, Establishment of a free society, based upon co-operative organization of production.

Third, Free exchange of equivalent products by and between the productive organizations, without commerce and profit-mongery.

Fourth, Organization of education on a secular, scientific, and equal basis for both sexes.

Fifth, Equal rights for all, without distinction of sex or race.

Sixth, Regulation of all public affairs by free contracts between the autonomous (independent) communes and associations, resting on a federalistic basis.

This, together with an appeal to the working men to organize, was published in Chicago, November 1883, by a local committee of four, representing French, Bohemian, German, and English sections, the head of the last being August Spies, who was hanged in 1887 for participation in the Haymarket affair in Chicago, 4th May 1886. This affair was the culmination of a series of encounters between the Chicago working men and the police, which had covered several years. The meeting of 4th May was called by Spies and others to protest against the action of the police, by whom several working men had been killed in collisions growing out of the efforts to introduce the eight hours' day. The mayor of the city attended the meeting, but, finding it peaceful, went home. The meeting was subsequently entered by the police and commanded

to disperse. A bomb was thrown, several policemen being killed and a number wounded. For this crime eight men were tried in one panel and condemned, seven—Spies, Parsons, Engel, Fischer, Fielden, Schwab, and Ling—to death, and one—Neebe—to imprisonment for fifteen years. The sentences on Fielden and Schwab were commuted by Governor Oglesby to imprisonment for life, on the recommendation of the presiding judge and the prosecuting attorney. Ling committed suicide in jail, and Spies, Parsons, Engel, and Fischer were hanged, 11th November 1887. On 26th June 1893 an unconditional pardon was granted the survivors, Fielden, Schwab, and Neebe, by Governor Altgeld. The reasons for the pardon were stated by the governor to be that, upon an examination of the records, he found that the jury had not been drawn in the usual manner, but by a special bailiff, who made his own selection, and had summoned a "prejudiced jury"; that the "state had never discovered who it was that threw the bomb which killed the policemen, and the evidence does not show any connexion whatever between the defendants and the man who did throw it," . . . or that this man "ever heard or read a word coming from the defendants, and consequently fails to show that he acted on any advice given by them." Judge Gary, the judge at the trial, published a defence of its procedure in the *Century Magazine*, vol. xxiii. p. 803.

There have been a number of outbreaks in recent years attributed to the propaganda of reform by revolution, like those in Spain and France in 1892, in which Ravachol was a prominent figure. In 1893, a bomb was exploded in the French Chamber of Deputies by Vaillant. The spirit of these men is well illustrated by the reply which Vaillant made to the judge who reproached him for

endangering the lives of innocent men and women: "There can be no innocent bourgeois." In 1894 there was an explosion in a Parisian café, and another in a theatre at Barcelona. For the latter outrage six men were executed. President Carnot of the French Republic was assassinated by an Italian at Lyons in the same year. The Empress Elizabeth of Austria was assassinated in September 1898. These events led to the passage by the United States Legislature of a law, in 1894, to keep out foreign anarchists, and to deport any who might be found in the country, and also to the assemblage of an international conference in Rome, in 1898, to agree upon some plan for dealing with these revolutionists. It was proposed that their offences should no longer be classed as political, but as common-law crimes, and be made subject to extradition. The suppression of the revolutionary press and the international co-operation of the police were also suggested. The results of the conference were not, however, published; and the question of how to deal with the campaign against society fell for a while into abeyance. More recently the attempt made by the youth Sipido on the (then) Prince of Wales at Brussels in 1900 recalled attention to the subject. The acquittal of Sipido, and the failure of the Belgian Government to see that justice was done in an affair of such international importance, excited considerable feeling in England, and was the occasion of a strongly-worded note from the British to the Belgian Government. The murder of King Humbert of Italy in July 1900 renewed the outcry against Italian anarchists. But even greater horror and indignation were excited by the assassination of President McKinley by Czolgoscz on the 6th September 1901, at Buffalo, U.S.A. (H. D. L.*)

ANATOMY.

MODERN ASPECTS AND METHODS.

THE acceptance of the doctrine of evolution has wrought cardinal changes in the position of anatomy as a branch of biology. So long as differing species of animals were believed to be genetically independent, resemblances in structure could only be interpreted upon some transcendental hypothesis, and no intelligible explanation could be given of the changes in form and arrangement which take place in almost every part during the process of embryonic development, or of such common phenomena as those of variation. The doctrine of community of descent has made possible a philosophic theory of morphology, which unifies and renders intelligible the otherwise incoherent facts of descriptive anatomy, and has opened up new fields of research.

The bent of the new Comparative Anatomy has been mainly genealogical. Assuming that resemblances in structure are due to community of descent, its progress has been stimulated by the endeavour to determine the phyla or genealogical trees of allied forms on the basis of a comparison of the sum-total of resemblances in structure and organization. For this purpose the elaboration of a complete anatomical ontology is necessary. The field of research in this direction has been widely cultivated by Professor Gegenbaur and his school. The method of embryology is useful as a supplement and check to the teachings of ontology. Every animal begins existence as an egg, a single cell, from which is derived by a gradual process of growth and differentiation the complete organic structure of the adult state. As the eggs of most metazoan animals are constructed on the same plan, and as with each suc-

cessive stage of development the range of resemblance in detail becomes more and more restricted, it has been supposed that the embryology of each individual is a recapitulation of the stages of the ontology of its ancestral forms. This serves as an excellent working hypothesis for purposes of classification.

Anthropotomy, in Great Britain at least, has hitherto profited less than any other branch of anatomy by the development of a philosophical morphology. The majority of those who study the subject are interested in it only so far as it is a handmaid to practical medicine and surgery, and its teaching is chiefly conducted by those who regard it from the professional standpoint, and by whom, naturally, the morphological aspect is subordinated to the technical. Attempts to remodel the nomenclature so as to bring human and comparative anatomy into line have not hitherto been encouraged by those authorities who exercise dominant influence in directing anatomical examinations. The spirit of the age will doubtless in time prove too strong for this obscurantism. On the Continent an effort has been made, especially by German teachers, to frame a uniform system of anatomical nomenclature. The names adopted by the Congress at Basel are largely those used by the school of Gegenbaur, and are not in all respects satisfactory. In England and France this nomenclature has been adopted by a few teachers only, and is used in a very few text-books. (For the best illustrated exposition of the Basel nomenclature, see Spalteholz, *Hand Atlas der Anatomie*, Leipzig, 1896.)

The importance of the study of the human type as a ground-work for morphological investigation has been admitted by all who are competent to judge. The body of

Inter-national nomenclature.

man has been scrutinized with the greatest minuteness by hundreds of workers, and knowledge of its details and of its variations is far more extensive and more accurate than that of any other animal.

The methods of anatomical study are of two sorts—those whereby the structures are unravelled as far as it is possible to discriminate them by the naked eye, and those whereby the finer texture of the tissues is displayed and examined by the aid of the microscope. The procedures for either microscopic or macroscopic study are twofold—dissection and the cutting of sections. The former is the art of separating the component parts, and of rendering them available for study by the removal of the connective tissues and fat which envelop them, while by the latter the relative anatomy of the parts can be best exhibited. Macroscopic sections are made of the whole body or limb, by freezing and cutting the sections with a fine saw, or by hardening the parts by the injection of formalin, and cutting with a large and sharp knife (Fig. 1). The topography of regions can be most satisfactorily made out by the examina-

FIG. 1.—Section through the thorax on the level of the nipple, showing the position of the heart and lungs. (Merkel.)

tion and comparison of successive sections made at short distances from each other. Sections for microscopic examination are most easily made of small parts of organs or whole organs hardened and embedded in some supporting material, such as paraffin wax or celloidin. These are cut into transparent films by means of a section-cutter, various patterns of which are in use. The best of these have an adjustment by means of which the sections can be cut of any required thickness, and the successive sections are preserved in the order in which they are cut. (The works of Braune, Rüdinger, and Symington give excellent plates of macroscopic sections of the body.) In preparing parts for dissection, it is of advantage that the tubular systems should be filled with some injected material, such as paint, wax, or starch. (Details of the modern methods in use are given by Grönroos, *Anat. Anzeiger*, 1898.) Microscopic sections are usually stained with certain soluble pigments, such as carmine, logwood, or eosin, which have the property of differentiating special tissues, such as protoplasm, cartilage, muscle, &c., colouring some and leaving others unstained. In modern anatomical technology, the number of such stains in use is large. (These methods of preparation are described in the text-books of histology by Schäfer, Stirling, Bolles Lee, &c.)

In recent years, great progress has been made in the knowledge of the details of human structure. Many parts, such as the convolutions of the brain, the folds of the intestine, &c., formerly supposed to be indefinitely variable as if they were arranged at haphazard, have been shown to be built up, even in their most minute

details, in a definite manner capable of formulated description; indeed, it is probable that no structure is so completely variable that its different conditions are incapable of reduction to law. (Of modern text-books, those of Bardeleben and Gegenbaur in German, of Poirier and Testut in French, are the best; English text-books, such as Gray, Morris and Gerrish are excellent from the descriptive side, but almost completely ignore morphology. Quain's work in its latest edition is of the nature of a compromise between the morphological and the descriptive.)

ULTIMATE ANALYSIS OF THE BODY.

The human body ultimately consists of *form-elements* of three sorts—cells, intercellular substance, and fibres. In its earliest form the whole organism was a single cell, and the first processes of growth consist in the multiplication of cells by division. A cell

Cells.

FIG. 2.—The cell and its process of division. A, Cell showing the network of spongioplasm; c, centrosome; n, nucleolus; n', nucleolus. B, First stage of division formation of chromatin wreath. C, Metaphase stage with spindle and centrosomes at the poles. D, Chromatin star of this stage, seen from above. E, Formation of diaster. F, The beginning of division and of the reconstruction of the nuclei. G, Stage of division nearly completed.

is not a homogeneous speck of protoplasm, but is a specialized structure exhibiting a comparatively complex organization (Fig. 2). The chief mass of the cell substance consists of a *cytomiton*, or network of protoplasmic threads, each of which often contains granules of some substance derived from the metabolism of protoplasm, the meshes of which are filled with a more fluid material or enchyrama. The nucleus also is complex and enclosed by an apparently structureless limiting membrane, within which is a network of at least two kinds of material. One portion is capable of being stained by carmine, and on that account is called *chromatin*. The other part of the *karyomiton* or nuclear net is incapable of being stained. Although

apparently casual in its form of meshwork, there is reason to believe that there are definite architectural laws according to which the chromatin filament is arranged, and some of these peculiarities in arrangement become obvious when a cell is about to divide (see *Ency. Brit.* vol. xx. pp. 416-417). In that condition the nuclear membrane disappears, and the chromatin filament forms a wreath through which a spindle of achromatin passes, at each pole of which a definite achromatic mass or centrosome accumulates, surrounded by a series of rays of achromatin. The equatorial chromatic wreath resolves itself into loops arranged with their closed ends directed inwards towards a central point and their free ends outwards. These loops undergo horizontal cleavage from looped to free end, and the looped ends pass along the surface of the spindle towards pole and antipole. When thus separated, the cell becomes mesially constricted and ultimately divides. Cells may be of very varied shapes and differ among themselves in structure and function, as noted in subsequent sections of this article; but they are, in the respects above enumerated, built on a common plan.

FIG. 8.—Connective tissue, showing cells, fibres, and ground-substance. $\times 350$. (Szymnowicz.) c, cell; e, elastic fibril; f, white fibril.

(For further particulars on cell-structure, see the text-books of histology above quoted, also the text-books of embryology of v. Kölliker, Minot, Kollmann, and Hertwig, and the several numbers of Carnoy's periodical *La Cellule*.)

The structureless material known as intercellular ground-substance varies in quantity in different tissues of the body, being sometimes only a slight cement layer joining contiguous cells, sometimes a copious substance in which cells are embedded. In all cases it has originated either by the exudation of material from cells or by the transformation of the periphery of a cell. Chemically, it is made up of some protoplasm-derivate, which varies in its nature in different tissues.

Fibres are not, strictly speaking, a single category comparable with cells. A fibre is an elongated, thread-like form-element, but fibres of different kinds have different morphological values. Some, such as nerve fibres, are elongated processes of cells, made of the same material as the cell-body, and often enclosed in a tubular sheath of the nature of an investing layer of intercellular material. Others, such as muscle fibres, are elongated cell-bodies whose cytomiton is so ar-

ranged that the contraction of the protoplasm of the cell can only act in one direction, shortening the fibre along its long axis. Fibres in connective tissue (Fig. 3) are for the most part of a different kind, consisting of elongated threads of intercellular substance differentiated from the material around them by virtue of the deposit of rows of granules or linear masses of some particular protoplasm-derivate. The nature of these granules determines the kind of fibre formed, and they are in this way marked off from the formless ground-substance with which they are surrounded, being usually separate from the processes of the branched connective tissue cells. It is possible, however, that some fibres in areolar tissue may be derived from elongated cell processes which have lost their connexion with a cell-body.

HISTOLOGY.

Form-elements when aggregated into continuous masses make up tissues, which may be classified according to their embryological history, their position, and their properties into four great classes—*Epithelial tissue*, *nerveous*, *muscular*, and *connective*. Epithelial tissue (see *Ency. Brit.* vol. i. p. 847 and xii. 5) is the lineal descendant of the superficial and the deepest of the three primary laminae of the embryo (*ib.* vol. xx. p. 418). It is usually disposed as the boundary layer of a free surface, preventing the leakage of the lymph or nutritive fluid in the underlying intercellular spaces. The amount of intercellular substance in epithelium is minimal, usually only represented by a layer of cement between contiguous cells. Epithelial tissues differ widely among themselves in properties according to the situation which they occupy; with these physiological variations are correlated morphological differences in the forms and structure of the cells.

The conditions determining divergence are degree of superficial pressure, of lateral tension, the nature of the material in contact with their free surfaces, and their degree of nutrition. When stratified in comparatively thick masses, as in the epidermis, the intermediate layers consist of *prickle cells* (see vol. i. p. 897), whose surfaces are beset with processes which join similar processes of other cells, leaving between them lymph spaces for nutrition. In some such cases, it appears from the observation of Cleland and Thomson that the most active cell multiplication is in this layer. In general, however, epithelial masses are sparingly provided with lymph channels, and cell growth proceeds from the deepest cells towards the surface.

Epithelial cells, whose surfaces are in contact with currents of air or of fluid, which requires to be passed on and not absorbed, are beset by *cilia* (see vol. i. p. 847). Recently it has been shown that the organization of these cells is much more complex than had been supposed (see Heidenhain, *Anat. Anzeiger*, 1899, No. 5), and that the cilia are connected with specialized portions of the reticulum of the cell substance, so that their motion is really a part of the motion of the whole reticulum. Such cilia are found in the nostrils, pulmonary air-passages, Eustachian and Fallopian tubes, and a few other places. (For further particulars concerning cilia, see Hennegruy, *Archives d'Anat. microscop.* 1898; Studnicka, *Sitzb. d. kgl. böhmischen Gesellsch.* 1899; Gurwitsch, *Anat. Anzeiger*, 1900.)

Nerve-endings are minute and with difficulty traceable in ordinary epithelium; but in some cases there is a much more abundant nervous supply, which reaches its climax in the organs of the special senses. The essential character of each of these is the presence of one or more layers of *sensory epithelium*, whose component cells are elongated on their free surface into one or more exceedingly fine rod-like processes. These and the reticulum of the cell-body are organized in a more or less complex manner according to the nature of the impulse to which they are designed to respond by vibration, and each cell is in direct connexion with a nerve-ending. The forms of sensory epithelium are described in connection with the specific sense organs (vol. i. p. 884 *et seqq.*). (For further researches, see Ramón y Cajal, "Le rétiné des

vertébrés," *La Cellule*, ix. 1893; Retzius, *Biologische Untersuch.* 1893, and Lenhossék, *Anat. Anzeiger*, 1893.) Embryologically, each sense-organ is a specialized area of dermal epithelium (except perhaps in the case of the tongue, whose surface is originally hypoblastic).

Epithelial cells which line pits or are otherwise placed in positions where they receive an abundant supply of nutrition (*gland-cells*) are usually highly metabolic, and have the power of separating from their substance by some process as yet unknown certain enzymes or other derivative material which they extrude, dissolved in some of the more fluid parts of the cell-content. These secreting cells undergo a physical change during their condition of activity, altering in appearance and reaction; but as yet no intelligible physical explanation has been given of this process, or of the correlation which exists between the specific enzyme produced by each gland and the physiological necessity of the part of the organism in which the gland lies. Sometimes single gland-cells occur in a continuous epithelium, as, for example, the mucus-secreting goblet-cells on the villi of the small intestines; but, generally, gland-cells are arranged at the bottom of tubular pits for the convenience of nutrition and of the accumulation of the secretion. The forms of the several kinds of glands depend on the degree of branching of these gland tubes. (On the structure of glandular epithelium, see Langley, *Journ. of Physiol.* 1889; and Nicolaïdes, *Centralblatt für Physiol.* 1889.)

Nervous tissue is the recipient of all stimuli, the seat of all sensations, the starting-point of all motor impulses, the regulator of vascular and other activities, and the controller of the processes of nutrition and secretion. It is connected with every organ, and its terminations are distributed in almost every tissue of the body. It is not to be wondered at, therefore, that its structure is of amazing complexity, or that our knowledge of it is as yet imperfect and fragmentary. The morphological conception of the organization of nervous tissue has undergone fundamental modifications in recent years, as the structure of its component form-elements has become better understood. The methods of staining introduced by Golgi and Weigert have rendered it evident that these elements are distinct from each other, and that their communications are indirect. The unit of structure which is called a *neurone* (Fig. 4) consists of three parts:—(1) A cell-body or *perikaryon*, containing a nucleus with a complex *karyomiton*; around this nucleus are other chromophile elements called *Nissl bodies*, capable of being stained by methylene blue, while the rest of the perikaryon consists of a twofold achromatic substance, a fibrillar or spongioplasm-element, supposed to be conductive, and a fundamental or trophoplasm-element, supposed to be the seat of metabolic chemical changes. (2) A single filament or *axon*, starting from the perikaryon by a cone of origin containing no chromatic elements. After a course of variable length this becomes coated with a sheath of myelin, and passes, often far afield, to its ultimate destination, terminating by branching into a short tuft of filaments which may be included in a muscle fibre or other end organ, or else may be in close proximity to, but not in contact with, the second order of processes, about to be described, of another perikaryon. On its way to its terminal tuft an axon may give off collateral filaments, which also may end in one or another of these ways. (3) From the other end of the perikaryon, usually from a part containing chromophile elements, there arises a series of one or more short, repeatedly-branching filaments, called *dendrites*, which form an arborescent outgrowth from the nerve-cell, and are related to the terminal tufts of the axons of contiguous cells. At the ends of

the dendrites are small enlargements called *gemmules*, and sometimes sharp-pointed processes called *thorns*. It has been supposed that the nerve currents in the dendrites are cellipetal and in the axons cellifugal. The motor nerves are all axons of cells, and it has been supposed that the sensory fibres are elongated dendrites.

The aggregations of neurones derived from the epiblast of the dorsal groove of the embryo make up the nervous centres. Other peripherally distributed neurones make up ganglia. In different parts of the nervous system the arrangement of the neurones varies in grades of complexity. In the simplest cases the dendrites carry the

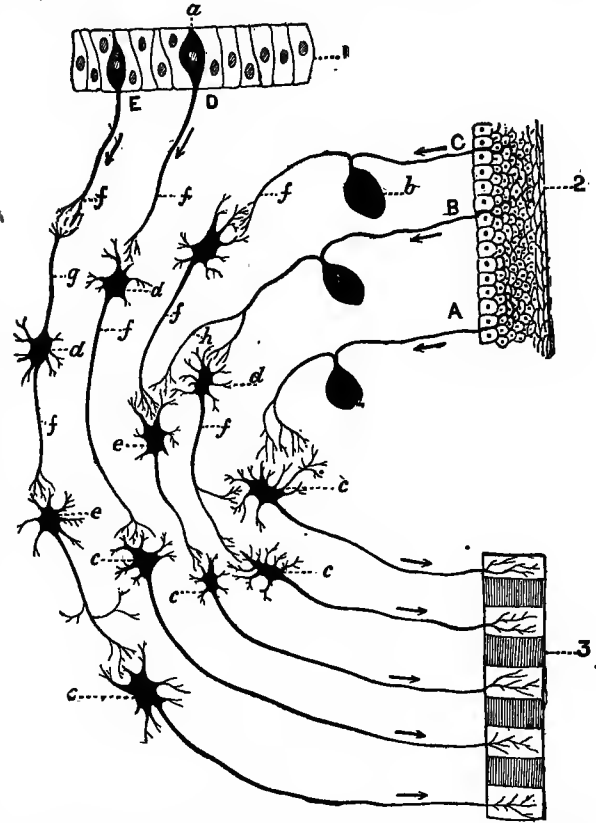

FIG. 4.—Diagram illustrative of the neurone theory. Each neurone consists of perikaryon (b, c, d, e), axon (f, g), and dendrites. A, Simple arc of two neurones, one having its dendrites as sensory recipient fibres in the skin (2), and its axon ending in branches forming a synapsis with the dendrites of the motor cell (c), whose axon ends in the muscle fibre (3). B, Arc in which a ganglionic neurone (d) is interposed between the sensory and the motor neurones. C, Arc in which an additional or associative neurone (e) is interposed between the ganglionic and the motor neurones. D, Arc in which the perikaryon of the sensory cell is in the recipient epithelium of a special sense organ (1) such as the retina. A ganglionic neurone (d) is interposed between this and the motor neurone. E, A similar arc with an associated neurone between the ganglionic neurone and the motor.

sensory impulse to the nerve-cell, wherein the wave of nerve force is in some unknown way reinforced, possibly by metabolic change in the trophoblast or the chromatic element, and is discharged as a motor impulse centrifugally along the axon to the muscle in which it ends. Sometimes the circuit consists of two neurones, one receiving and transmitting the sensory stimulus by its axon to the vicinity of the dendrites of the cell whose axon goes to the muscle. Sometimes a third or even a fourth association-system of neurones may be interposed between the tuft of the first axon and the dendrites of the last or motor cell. The method of relationship between the neurone networks is called *synapsis*; and there is reason to believe that the degree of approximation of the filaments in these is not always constant, but that sometimes the contiguity of some groups of processes may become close, while in other instances they may recede from each

other, and thereby the conveyance of whatever influence travels from neurone to neurone may be accentuated or hindered. The details of these groupings and of nerve-endings will be considered in connexion with the splanchnology of the nervous system. (For further particulars of the neurone theory, see Hoche, *Die Neuronenlehre*, Berlin, 1899.)

Each bundle of processes which leaves the central masses of nerve-tissue in its course towards its peripheral termination is called a nerve. The courses of these nerves can be

Nerves. followed by dissection, but the modes in which they end can only be ascertained by methods of staining, section-cutting, and microscopical examination. Within the central masses of nerve-tissue the courses of the fibres are intricate and obscure, and methods of staining and section give only imperfect differential criteria, whereby individual bundles may be traced. The two methods which are most instructive are those which may be respectively called the experimental and the embryological:—(1) When an axon is detached from its cell it degenerates through all its length to its terminal tuft; so by dividing the axons coming from any group of cells their course, as distinguished from otherwise arising axons, becomes apparent in a series of successive sections stained to show such as are degenerated. (2) It is found by observation on developing nerves that some fibres acquire their myelin sheath sooner than others; so by making successive sections of an immature part, and staining the myelin sheath, any group of fibres already myelinated can be differentiated from those not as yet invested with this layer.

Muscle is contractile tissue derived from the cells of the middle embryonic layer and consisting of elongated fibre-like cells, whose reticulum is regularly disposed, and whose enchylema or trophoplasm is charged with myosin and other proteids. These protoplasm-elements are so organized that when the cell contracts its two extremities are approximated. The three varieties of muscle—unstriated, cardiac, and striped—as well as some of the views which are currently held respecting their minute structure have been referred to in vols. i. p. 856 and xii. p. 8; but as yet the real nature of its organization has not been made out, and it is not improbable that many of the appearances described by observers are factitious, produced by the actions of reagents. The observations of Ramón y Cajal and van Gehuchten have led them to regard the fibre as consisting of a reticulum comparable with the cytomiton of a cell in whose interstices is an inter-reticular enchylema. Rollett, on the other hand, regards the reticulum as being composed of partitions of non-contractile sarcoplasm around a series of contractile sarcostyles. Merkel and Engelmann believe that the fibre consists of alternating masses of two materials which differ in their optical properties. One of these is anisotropous, and this may possibly during contraction absorb, or during relaxation discharge, a fluid yielded to it by the isotropous band, altering thereby its width and surface tension. In view of the conflict of opinion new methods of research are required before any positive pronouncement can be made as to the ultimate histological analysis of the muscle fibre. (For discussions of these views, see van Gehuchten, *Anat. Anz.* 1888-89; v. Kölliker, *Gewebelehre*, 1890; Rollett; *Wiener Sitzungsber.* 1889; Engelmann in *Hermann's Physiology*, i. 2; and M'Dougall, *Journ. of Anat.* Jan. 1898.)

Whatever may be their intrinsic structure, the mode of grouping of striped or voluntary fibres is easily ascertained. They are surrounded by a fine areolar tissue, called *endomysium*, in which the nutrient capillary vessels ramify and by means of which they are united into bundles. Each such fascicle of fibres is surrounded by an areolar sheath or *perimysium*. Groups of these bundles are united into larger masses, which are so arranged as to be capable of acting as motor units in the economy of the body. Each of these is invested with an areolar sheath, and is called a *muscle*. The ends of each muscular fibre are attached to the connective tissues with which they are in contact. In general, there is a filament of white fibrillar tissue firmly united to the end of each fibre, and the collective masses of these filaments at the extremities of a muscle

are called its *tendons*. By these the muscle is tied to the parts of the skeleton, from and on which it acts. The lengths of the fleshy fascicles of muscular tissue are proportional to the mobility of the point of insertion, being just long enough to draw that part to the extreme of its possible excursion; so, if the distance between origin and insertion exceed this, the tendons at either or both ends are of sufficient length to occupy the remaining space. It must be remembered, however, that, embryonically, tendon and muscle arise independently, and that their connexion is secondary.

Muscles are apt to degenerate from want of use. In extreme cases the contractile tissue vanishes, leaving its connective framework as a fibrous mass. This takes place by natural selection, as muscle is an expensive structure to maintain owing to the amount of nutrition it requires. On this account, also, the fleshy bellies of muscles tend to become accumulated as near the base of supplies as possible; that is, as near the main vessel of the limb or the axis of the body.

The arrangement of the fascicles is not the same in all muscles. In some they run in direct lines, from origin to insertion, as in the rectus abdominis; in others, such as the pectorals, they converge from a wide origin to a narrow insertion so as to concentrate their useful work in moving one point. Muscles of the former group are called prismatic or bandlike; those of the latter, triangular or pyramidal. In a third group the fibres pass obliquely from origin to insertion, so that their action is decomposable into two components, one of approximation and one of translation, the relative sizes of which depend on the angle of the slant of the fibre with regard to the axis of the bone into which they are inserted. Owing to the exigencies of the formation of the skeleton most muscles belong to some species or other of this third class of rhomboidal muscles. A very common special case of this group is that of *penniform* muscles, in which a large number of short fibres are attached obliquely to an elongated tendon, as the barbs of a feather are to its axis. By this formation the number of short fibres in a slender muscle can be greatly increased without its becoming unduly thickened at any point. There is a certain small loss of useful work owing to the obliquity of the fibres, but this approximation-element is generally a negligible quantity, being only equal to the product of the force into the sine of the angle, which is usually very small.

One or more nerves or blood-vessels enter into each muscle. The point of entrance is at that spot at which the muscle moves least on the contiguous structures, and is usually on the aspect which is farthest from the surface, and, in the case of the vessels, nearest to the main artery of the limb. The nerve on entering breaks up into branches in various ways, the exact pattern of division depending on the arrangement of the fibres in the muscle. (See Disse in *Journ. of Anat.* Oct. 1897.) Ultimately, a nerve-twig passes into each muscular fibre and terminates in an end plate. The proportion between the number of nerve fibres entering a muscle and that of muscle fibres is in the external rectus oculi 1:8, in the soleus 1:350. In general, the nerve to each muscle comes from a single source, but in a few cases muscles are diploneural. Thus the brachialis anticus is supplied both by median and musculo-spiral nerves. The double supply generally indicates the fusion of two muscle germs, which have originated independently. When the area of origin of a muscle includes parts which are discontinuous or independently movable, the portion arising from each such part remains partially separate from the rest, and the muscle becomes two-headed. This condition may also occur from the interjection of a vessel or nerve, or from the synthesis of separate segmental elements in the one muscle. In like manner, a double insertion may arise from the separate mobility of the structures into which the muscle is inserted. Some muscles present two or more successive fleshy bellies, and are called in consequence digastric or polygastic. In such cases the several bellies have been separate morphological units, and have independent nerve-supplies.

Connective tissues are derived from the middle embryonic lamella and make up more than two-thirds of the body, forming its framework and the supporting skeleton of the more metabolic and physiologically active elements of each organ. Every epithelial layer is based on a lamella of this tissue; every muscular fibre is sheathed by a connective layer, and is attached to, or acts on, the connective tissues around its extremity. In this tissue there are three form-elements—(1) cells, which are usually flattish, often processed, rarely or never contractile, and consist of a distinct cell-wall and a comparatively small amount of protoplasm; (2) inter-cellular substance, copious in amount and traversed by

**Nervous
and
vascular
supply.**

**Connective
tissue.**

numerous lymph canals; and (3) fibres, which may be of two kinds, either white, non-extensile, arranged in more or less wavy bundles of parallel fibres, or yellow, highly extensile and resilient, arranged in frequently dividing and uniting bundles.

There are many varieties of connective tissue in the animal body (see i. 849 and xii. 6). The typical form is that called *areolar tissue* (Fig. 3). This consists of irregularly-interlaced wavy bundles of white and yellow fibres in a copious ground-substance, through which are scattered a number of flattish or branched cells. When immature the ground-substance is continuous and abundant; but in the adult it diminishes and becomes broken up by the formation of gaps or spaces, which give it a somewhat spongy texture, so that it can be inflated with air or infiltrated with fluid. This tissue is almost universally diffused in the body, varying in texture in each part according to local requirements. Under each layer of epithelium it forms a dense, almost structureless, *basement membrane*. In some organs its meshes are numerous and fine, containing entangled in them large masses of white lymph-corpuscles, which congregate and multiply in these spaces. This form is known as *adenoid tissue*. In some regions groups of connective tissue-cells are closely packed together, and their cell-contents become charged with oily or fatty material. Masses of this nature make up *adipose tissue*. In other cases the fibre elements, either white or yellow, preponderate. The white fibrillar is the toughest tissue in the body; a thread of it, measuring 1 square millimetre in section, bore without rupture a weight of 8940 grammes, while a cord of yellow tissue broke with a weight of 4040 grammes. *Cartilage* and *bone* are special varieties of connective tissue. In the former the tissue makes solid masses, in which the cells, either separate or in small clusters, are embedded in a hyaline matrix of ground-substance with or without fibrous elements. In some invertebrates and lower vertebrates a form of cartilage exists which contains mucin instead of chondrogen, recognized by its staining yellow with thionin. Bone is characterized by the calcification of its ground-substance, which

Bone. becomes infiltrated with lime salts, while for the most part the fibres and the branched connective corpuscles remain uncalcified (see vol. i. p. 852). The physical properties of bone fit it in an eminent degree to form the skeleton of the animal body. When its specific gravity, its breaking limit with tensile strain, its crushing limit when subjected to pressure, and its modulus of elasticity are compared with those of other materials, this superiority becomes apparent. (See Lesshaft, *Theoret. Anat.* Leipzig, 1892.)

In the following table the numbers in the second and third columns are the weights in pounds avoirdupois required to break or crush a square rod of the material 1 mm. in diameter. The modulus of elasticity is the weight in pounds which, if these substances were perfectly elastic, would be required to lengthen the square rod to twice its original length. To compare these so as to determine the skeleton-building suitability of each material, the number in each column should be divided by the specific gravity of the material:—

Substance.	Sp. Gr.	Tensile.	Crushing.	Elasticity.
Steel	7.816	225	319	46,300
Wrought-iron	7.788	90	48	41,887
Cast-iron	7.207	28	160	...
Bone	1.870	26	33	5,291
Oak	0.845	14	10.5	2,425

The important factor that the skeleton must present a surface of sufficient extent to give attachment to the muscles of the body makes it necessary that the material of which it is made must be of comparative lightness. Bone is the most vascular form of connective tissue and the most active in nutritive changes. In general, connective tissues are low in vitality; their elements con-

tain but little protoplasm, and in consequence they easily suffer necrosis.

All forms of connective tissue begin as an indifferent embryonic mesenchyma, whose subsequent differentiations are reactions due to the influence of environing conditions, which are usually definite and recognizable. Hence the history of the connective tissues of the body forms an important chapter in dynamical ontogeny. The chemical relations of the different forms of connective tissue are generally characteristic. The white fibrils and ground-substance of areolar and white fibrillar tissue yield gelatine on boiling, cartilage yields chondrin, and yellow tissue consists of a substance which resists acetic acid and boiling water, and is named elastin. The animal part of bone in most respects agrees with that of white fibrillar tissue. The process of ossification has been described in vol. i. p. 855, where it is noted that it may take place either in cartilage or in membrane. This is an important consideration in the determination of bony homologies, for a bone which was originally cartilaginous is morphologically of a different order from one which started as a membrane. The reason is not far to seek. It is not that the processes differ intrinsically, but the early stages of the ancestral history recapitulated in its embryogeny must be diverse as the embryonic tissue has become so diversely differentiated. The history of the progress of ossification has been greatly elucidated by the use of the Röntgen rays, whereby the bony nuclei can be detected at their first formation, and their growth and union can be traced in the living adolescent.

In some cases in which large clefts occur in masses of areolar tissue the tissue forming the boundaries of such clefts consists mainly of flattish connective cells, which in some cases are close enough to simulate pavement epithelium. Such a layer is called *endothelium* to distinguish it from the true epithelium. This term, though etymologically objectionable, is in the main convenient, and is in general use. These clefts are of four kinds—joint cavities, bursæ, sheaths of tendons, and serous cavities. In *joint cavities* the surfaces of the bone are covered with cartilage, and have no endothelial coating, but the ligamentous side-wall of the joint is lined with a specially smooth connective layer, named *synovial membrane* (Fig. 5). On the surface there are often patches of endothelium, although never a continuous layer of such cells. Groups of endothelial cells, however, are often clustered on fringes at the margin of the bones in these cavities, and these secrete a mucilaginous exudation called *synovia* (vol. i. p. 833). *Bursæ* are clefts between planes of firm areolar or fibrillar tissues which glide on each other. These are also lined by synovial membrane, but never present a continuous endothelium; indeed, in many bursæ these are only represented on a few of the synovia-secreting processes. The same is true of the sheaths of tendons. *Serous membranes* form a separate category, for, while in

Fig. 5.—Vertical section through knee-joint, with the bones somewhat drawn apart, showing the synovial cavity of the joint (j) and the bursæ (b) in its vicinity.

These are also lined by synovial membrane, but never present a continuous endothelium; indeed, in many bursæ these are only represented on a few of the synovia-secreting processes. The same is true of the sheaths of tendons. *Serous membranes* form a separate category, for, while in

the higher vertebræ the coelom or body cavity which they line is formed by a splitting of the mesoblast, the comparative embryology of this cavity shows that originally in the most archaic vertebrates it was formed by the outgrowth of diverticula from the primitive gastræal cavity. It is consequently possible to sustain the thesis that the apparent delamination in the higher forms is due to the superposition of a series of processes of development which occur successively in the lower, but simultaneously in the higher vertebrate. Hence it is conceivable that the lining material of the coelom may be not an endothelium, but a true epithelium. The same may possibly be the case in the great blood-vessels. At the same time it must be remembered that it is not possible to draw hard-and-fast lines between the derivatives of the several germ layers, whose distinction the one from the other is not so definite as was once imagined. Serous membrane is always lined by a continuous layer of pavement cells, resembling pavement epithelium in almost every respect, and the same is the case with the blood and lymph vessels.

SPLANCHNOLOGY.

A mass made up of various tissues united so as collectively to discharge some special function is called an *organ*. Proximately the human body consists of an assemblage of organs arranged in a definite manner, and the study of the structure of these organs and of their relative positions constitutes the subject-matter of Descriptive Anatomy. Organs may be classified physiologically according to their respective offices into seven groups—(1) those of protection and support (skeletal); (2) of motion (muscles); (3) of sensation, the seats of the reactions dependent on and related to sensation and psychic process (nervous); (4) those whereby food is taken in and assimilated (digestive); (5) those whereby the nutritive material is distributed to the tissues (circulating); (6) those whereby waste products are got rid of (eliminative); and (7) those by which reproduction takes place. Morphologically, organs may be divided into two groups, according to their relation to the originally segmented constitution of the body. The human body, like that of all vertebrate animals, is made up of a chain of segments, each of which is more or less built on a common plan. The organs of the 1st, 2nd, 3rd, 5th, and some of those of the 6th group are segmental in original plan, although in the course of development this characteristic has become obscured. Those of the 4th and 7th, and some of those of the 6th group show no sign of ever having been segmented at any stage in their ontogeny.

I. Organs of Protection and Support.—All the active tissues of the body are supported on a framework of connective tissues, or else are contained in spaces bounded by lamellæ of these tissues, which thus constitute the skeleton of the organism. (The word skeleton is popularly limited to the bony framework, but, morphologically, all the connective tissues are equally parts of the vertebrate skeleton.) A layer of extremely condensed areolar tissue invests the whole body, forming the true skin, *cutis* or *dermis*. This is truly skeletal, and in some lower vertebrates is the only tissue in which ossification occurs. Beneath this is a laxer layer, also of areolar tissue, differing from the last chiefly in its lesser density, in its containing more or less fat in its meshes, and in its being traversed by vessels and nerves, which do not end in it as they do in the denser *cutis* which invests it. This layer is called *superficial fascia*, and, like the skin, it is continuous over the whole body.

Beneath the superficial fascia there is in most parts of the body a firm, thin layer of white fibrillar tissue, which covers the muscles and is attached to those prominences

of bone which project beneath the skin. To this the name *deep fascia* is given. Partitions of this material dip in between groups of muscles, and are called intermuscular septa. Other lamellæ form sheaths for vessels, nerves, and viscera. The deeper connective tissues forming the main axis of the body, to which the name skeleton is commonly limited, are composed of bone, cartilage, and fibrous tissues, and are disposed segmentally. They consist (1) of the vertebral column, and (2) of the skeletal walls of the two great tubes of which the vertebrate body is made up, the dorsal or neural, and the ventral or visceral. The walls of these tubes are united to the investing layers of deep fascia by four longitudinal partitions—one mediodorsal, one medioventral, and two lateral—subdividing the body wall into four areas, two dorso-lateral and two ventrolateral.

At their first appearance in the embryo the continuity and segmental arrangement of these connective masses and partitions is obvious; but in their later conditions, when parts of this skeletal apparatus are transformed into cartilage and bone, though to some extent appearances of segmentation still persist, yet these are often of derivative origin, and do not coincide with the primary segmental divisions. For in the course of development the primary intersegmental clefts are in part seen to fade and a secondary series to appear; these, instead of coinciding, are for the most part alternate with them. This secondary segmentation occurs especially in the tissue around the notochord or unsegmented axial rod (vol. i. p. 830). This notochord is no part of the skeleton; it was originally a canal, but in the absence of any animal which preserves this structure as such it is difficult to understand what was its original function (Fig. 6).

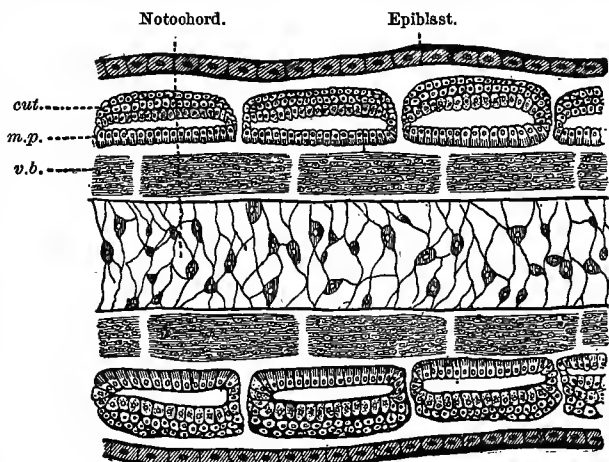

FIG. 6.—Diagram constructed from several sections of the vertebral region of the embryo shark. Showing the formation of vertebral bodies (*v.b.*) around the notochord, by the rearrangement of the scleroblasts or inner cells of the original protovertebrae, the lines of segmentation of these rearranged segments being alternate with those of the original protovertebrae, as shown between the muscle plicae (*m.p.*) and cutis plicae (*cut.*), from which the muscular system and dermis are respectively developed. The epiblast gives rise to the cuticle. Between the muscle layer and the cutis layer is the segmented portion of the coelom.

It probably was an archaic form of alimentary canal, around which were disposed the segmented skeletal and other tissues. The connective tissues which surround it become the successive vertebral bodies, and their uniting fibrous discs, from the former of which the neural arches project dorsally, and the costal or rib arches ventrally.

To the description of the vertebral column in vol. i. p. 821 it is only necessary to add that the morphological relationships of the parts in successive vertebræ are not so simple. Each vertebral body originates as two separate elements—one a perichordal ring, arising in two symmetrical parts, one on each side of the notochord, and a second or hypochordal arch connected with the bases of the neural and visceral arches, lying on the ventral side of the perichordal elements and on a level with the interval between contiguous perichordal rings. This hypochordal element merges with the perichordal in all vertebræ, except the first cervical. In this it remains separate and ossifies as the anterior arch of the atlas, while the corresponding perichordal ring becomes the odontoid process of the axis. The successive vertebræ

throughout the whole column consist of comparable parts modified in each region to suit the mechanical condition of the region. The most variable portion of each vertebra is the transverse process, an outgrowth from the base of the neural arch, which is usually multiple. It is not so much a morphological unit as a variably-arranged area for the attachment of oblique intervertebral muscles. In the cervical region it is tripartite—(1) its dorsal portion existing as a mere roughness on the dorsal side of the articular mass for muscular attachment; (2) its ventral portion is fused with the rudimental costal process; and (3) its intermediate part, which projects into the lateral septum, is joined at its lateral end, to the ventral portion, bounding with it a hole for the ascent of the vertebral artery. In the thoracic region the parts corresponding to the 1st and 3rd of these elements unite into a single transverse process, while the ventral part is flattened into a costal articular facet. The ribs, which are detached extensions of these costal processes, do not really articulate with the bodies of the vertebrae, but in foetal vertebrae it can be seen that the entire rib articulation is on the neural side of the suture between the neural arch and the centrum or body. The three elements are distinct in the 12th thoracic vertebrae. In the lumbar region the ventral part is, as in the cervical, inseparable from the costal element, making with it the process that is usually erroneously described as the transverse process. The two others exist as rough spurs, called respectively the mammillary and accessory processes. The human vertebral column in its earliest stage consists of thirty-eight vertebrae. Of these the two hindmost vanish before chondrification takes place, and the four which precede these unite into an irregular mass, the last of the four pieces of the coccyx.

The appendicular skeleton is described in vol. i. p. 838. The morphological nature of the vertebrate limb is still a disputed point; but the balance of evidence is in favour of

Nature of limbs. Balfour's theory, that each limb is the surviving part, anterior or posterior, of a lateral ridge, which originally extended along the side of the vertebrate body, and each consists of material derived from at least seven successive segments. Gegenbaur, however, has made out a plausible case for the hypothesis that the limbs are modifications of the processes of a gill arch, and Graham Kerr has proposed to regard the limbs as derived from external gills (*Proc. Camb. Philosoph. Soc.* 1889).

The parts of the skeleton of the human *forelimb* present certain characters which distinguish them from those of other mammals. The scapula is longitudinally elongated and transversely short, so that its maximum breadth only equals about 0.70 of the length. This "scapular index" is usually greater in the black races, and is higher in the foetus than in the adult. The humerus in man exceeds the radius in length as 1:0.7, the numerical relation being known as the humero-radial index. This also is larger in the lower races. The human thumb is perfectly opposable to the other digits, as is that of no other vertebrate. There are normally eight bones in the human carpus, but embryonically a ninth or *os centrale* is present in vestige, fusing at an early period with the scaphoid or semilunar, and only remaining distinct as a rare anomaly, although its rudiment is by no means uncommon. The pisiform bone of the human carpus is in all probability the reduced vestige of an obsolete sixth digit, and is not, as has been supposed, a sesamoid bone. The *hip-bone* presents markedly different characters in the two sexes, which can be recognized as early as the fifth month of foetal life. On account of these differences the shape of the cavity of the pelvis bounded by these bones is also distinctive, even in the foetus. In the males of the white races of mankind the sagittal (antero-posterior) length of the pelvis is, in average cases, to the coronal (transverse) length as 80:100; but in those of the black races it is related as 95:100. A slight difference has been observed in the level of the articulation of the hip-bone with the sacral vertebrae at different periods of life, the tendency being for the former to rise to a higher level as development advances. In the earliest period of foetal life at which these elements can be distinguished the first sacral vertebra is not at all involved in the articulation; but as age advances it gradually becomes included in the joint, and occasionally the twenty-fourth vertebra becomes also on one or both sides directly articulated to the hip-bone, and correspondingly incorporated in the sacrum.

The *femur* constitutes usually about 0.275 of the individual stature; but this proportion is not constant, as this bone forms a larger element in the stature of a tall than of a short man. The human femur presents also a concave popliteal surface, thus differing from that of Pithecanthropus, whose popliteal surface is convex. In the bones of some races the dorsal ridge of the thigh-bone (*linea aspera*) projects as a prominent crest causing the bone to appear "pilastered," a condition the amount of which is indicated by the increased relative length of the sagittal to the coronal diameter of the bone. Pilastering, though characteristic of lower and primitive races of man, is never found in the anthropoids. The upper third of the femur in some races is sagittally flattened, a condition which

is called *platymeria*. Its degree is indicated by the excess of the coronal over the sagittal diameter in this region.

The *tibia* in most civilized races is triangular in the section of its shaft, but in many savage and prehistoric races it is two-edged. The condition is named *platycnemia*, and is indicated by the proportional excess of the sagittal over the coronal diameter. The foetal tibia has its head slightly bent backwards with regard to the shaft, a condition which usually disappears in the adult, but which is shown by the prehistoric tibiae found in the cave of Spy. In races that squat on their heels the front margin of the lower end of the tibia is marked by a small articular facet for the neck of the astragalus.

The *fibula* is a variable bone. In prehistoric and savage races its several surfaces are often deeply channelled. In foetal life its lower ankle-swelling is smaller than the inner ankle of the tibia, but this relation becomes reversed in the adult. The human foot is plantigrade, the metatarsal bone of the great toe being nearly parallel to those of the other toes, unlike those of the anthropoids. Very often in the adult the second and third phalanges of the little toe are ankylosed together. This is no new thing nor is it necessarily a product of civilization. The writer has found it thirty times in the feet of ancient Egyptians, and once in those of an aboriginal Australian. The intermembral relation of humerus and femur is important in physical anthropology, as are also the relative lengths of the femur and tibia.

The varieties of cranial shape which are distinctive of the different races of mankind are due especially to the interaction of four factors—(1) brain size and shape; (2) dental size and degree of development of the muscle of mastication; (3)

Skull. the sizes of the several sense organs; and (4) the sizes and extents of certain muscular areas. The methods commonly in use for estimating these varieties are numerical indexes, which are the centesimal relations of certain measurements. These are convenient although often fallacious. Thus, for example, brachycephally or broad-headedness, indicated by the breadth being more than .80 of the length, may be due to the survival of an infantile character, as in Negritos, or to a secondary increase in the width of the hinder part of the frontal cerebral lobes, as in the Teutonic Europeans. Similarly dolichocephaly (with the breadth .75, or under, of the length) may be due to increased length of frontal and parietal areas of the brain (indicated by increased preauricular length), or to diminution of the parietal width and increased occipital length. Most other composite cranial measurements hitherto made are equally faulty.

The human skull is frequently the subject of deformation, due to premature union of some of its sutures constraining its growth. Thus, if the two parietals unite in foetal life or infancy, the skull becomes *scaphocephalic*, as represented in vol. i. p. 832, Fig. 14. When the union is of the coronal suture, the skull becomes short and high, or *thyrscephalic*; if the halves of the frontal unite before birth, it is wedge-shaped or *trigonocephalic*. The vertebral theory of the skull has been discussed (vol. i. p. 831), and is now definitely abandoned by all morphologists. On the other hand the original segmentation of the cephalic region has been abundantly demonstrated; the only difference of opinion among observers has been in the estimation of the number of segments in the cephalic region of the primitive vertebrate. These segments, however, had lost their distinctness even before the cartilaginous cranium had become developed, so that there is no real segmental value in the elements of this, still less in those of the bony skull. The only place in which segmental elements can be distinguished is in the occipital region, which is in structure transitional between the head and the vertebral column. (For an excellent account of the human skull, in which the many new morphological details due to recent investigation are set forth, see Graf Spee in *Bardleben's Handbuch der Anat.* i. 2.)

To the account of the joints and ligaments of the human body in vol. i. p. 834, it need only be added that the ligaments are not all of the same morphological value. The capsules of most of the joints are derived from the connective **Joints.** tissue which forms the circumference of the primary articular cleft in the embryo (vol. i. p. 833, Fig. 16); but the accessory or lateral ligaments are often of secondary formation, derived from displaced tendinous appendages to muscles or intermuscular septa, or they may even be the connective sheaths of muscles which have lost their fleshy substance. The function of ligaments is chiefly to supplement the muscles in protecting joints. They are generally weak where the muscles are strong, and it is noteworthy that joints are more frequently dislocated at the places where the muscles are feeblest, irrespective of the strength of the ligaments. The menisci, whose formation has been referred to and illustrated in vol. i. (p. 833, Fig. 17), are not always the simple survivals of an interjected layer of the capsule; in some cases, as in the triangular cartilage between the ulna and carpus, the cartilage may contain a vestigial skeletal element, and the same may be true of the sterno-clavicular cartilage.

II. *Muscular System* (see vol. i. p. 834 sq.).—The voluntary muscles of the body may be grouped in three series—those derived from the muscle plate of the proto-vertebræ; those originating in the somatopleure; and those originating in the nephromere or region of the segmental organs. The muscles arising in the splanchnopleure are the unstriped muscles of the viscera.

From the muscle plate arise the axial muscles of the dorsal series, including the deeper layers of the muscles of the back. The orbital muscles also originate from cephalic muscle plates. In the trunk this series is trilaminar, including (a) the longitudinal muscles of the spinal column, (b) the intermediate oblique series of semispinales and multifidi, and (c) the deep, short interspinal and rotator muscles, which stretch from vertebra to vertebra. All these are innervated by the dorsal branches of spinal nerves, and they are limited dorsally by the strong dorsal fascia, and ventrally by the lateral intermuscular septum.

The somatopleural muscles originate in the body wall beyond the edge of the muscle plate. As it is from this structure that the limbs are outgrowths, these muscles may be divided into two series—those of the trunk (ventroaxial), and those of the limb (appendicular). They are all innervated from the ventral branches of the spinal nerves and lie on the ventral side of the lateral septum. These muscles are divided into laminae. A superficial external oblique layer is continued in the thoracic region over the ribs. A second or internal oblique layer becomes intercostal in the thorax. A third or transverse layer lies on the visceral side of the ribs. On either side of the medio-ventral line these three layers are represented by a continuous mass, the rectus abdominis, from which, sometimes, the pyramidalis is a superficial and partial delamination. Occasionally there is a superficial lamella attached to the skin—the panniculus, or skin muscle—which is only a delamination of the superficial layer, as shown by its development and innervation. The limb muscles are continuations of the supracostal stratum, modified by their connexions with the bony parts of the limb. They are throughout divisible into a dorsal and a ventral series, each of which is innervated by branches derived respectively from posterior and anterior divisions of the ventral trunks of the spinal nerves of the segments represented in the limbs. Those who hold the Gegenbaur or Graham Kerr hypothesis regard the multiple innervation of the limb as evidence of the secondary annexation of other nerves, in consequence of a gradual slipping backwards of the limb. These dorsal and ventral muscles of the limb are grouped into those attached to the limb girdle and those which extend to the first, second, or to the terminal elements of the limb ray. There is a certain general resemblance between the muscles of the two limbs as they arise from similar muscle-sheets; but as in all land-animals the fore and hind limbs are of necessity different in their mechanical relations, the rôle of the fore and hind limbs being essentially different in quadrupedal progression, these sheets from the first have undergone cleavage in different ways. Therefore, it is not possible precisely to homologate the different muscles of one limb with their equivalents in the other. The innervation of these sheets of muscle, however, shows that around the shoulder or hip there are four groups, which may generally be called abductor, adductor, flexor, and extensor; in those around the elbow as well as in those of the hand or foot there are three series, although two of these are confluent in the leg, where also the radial marginal group of muscles is absent. An important difference is to be noted between the muscles of the hand and foot in the position of the axis of movement of the digits. In the hand the short muscles are arranged so as to adduct to, or to abduct from, an axis

passing down in the line of the middle finger, whereas in the foot the axis from and to which the muscles draw the toe passes down in the line of the second toe.

The muscles which are derived from the nephromeric region, sometimes called hypaxial or hyposkeletal muscles, are a few, small aberrant somatopleural slips which lie on the ventral face of the vertebral bodies and pedicles, such as the longus colli and others on the same horizon. They are innervated by branches from the ventral divisions of the segmental nerves.

The muscles of the human body exhibit very many varieties, an exhaustive study of which is given in Le Double's *Variations du système musculaire de l'homme*, 1897.

III. *The Nervous System*.—Considerable advances in knowledge and some changes in interpretation have been made since the writing of the remarks in vol. i. pp. 858-884. The vertebrate body in its early embryonic stages is made up of a succession of segments, in each of which there is a segmental nerve distributed to the parts of the segment. In process of development irregularities in the growth of the component elements obliterate or obscure the definition of the primitive division; but there is reason to suppose that the nerve constituents are more constant in arrangement, and furnish more accurate indications of the original segmentations than do the other tissues or organs. In the head, where the traces of original segmentation are practically obliterated, owing to the rapidity with which change succeeds change in early embryogeny, almost our only guide to unravel the morphological history is that furnished by the cranial nerves. The course of a typical segmental nerve is described in vol. i. p. 867. Such a nerve traced centripetally resolves itself into two roots, a dorsal and a ventral, close to its place of connexion with the spinal cord. The fibres making up the ventral root enter the spinal cord along its antero-lateral groove, are continued into the grey matter of the anterior horn, and prove to be the axons of the large branching cells of that horn. These neurones form the efferent or motor system whose terminal tufts are enclosed in the fibres of the voluntary muscles and other structures throughout the body. Some of the efferent axons of a spinal nerve end in tufts beside the dendrites of nerve-cells clustered in small visceral ganglia, which are arranged in a chain on the ventral surfaces of the vertebral bodies. To these the name *sympathetic ganglia* is given. The axons of these cells are distributed to viscera and vessels. The fibres making up the dorsal root are in essence processes of cells which form a series of ganglia close to the postero-lateral groove of the cord. Each cell of these ganglia gives off a short process, which divides into two branches that diverge from each other nearly at right angles, like the component halves of the horizontal stroke of the letter T. One of these is the fibre we have traced from the periphery as the sensory element of the spinal nerve; the other passes into the spinal cord, there to break up and to be connected synaptically with the neurones of other systems. The primordial segmentation of the vertebrate nervous centres has become overlaid and masked by the development of groups of neurones, which combine, co-ordinate, and otherwise influence the relations of the segmental nerve-cells. This is true of the spinal cord, but much more so of the brain.

As an account of the spinal cord has been given in vol. i. p. 865, it is only necessary here to trace the courses of the component systems of neurones in terms of the parts of the cord there described:—(1) Spinal cord. Around the dendrites of the large cells of the anterior horn are the end-tufts of axons, which can be traced up to the medulla oblongata. These collectively

form a thick white band, the *crossed pyramidal tract*, that lies on the lateral side of the dorsal horn. When it reaches the apex of the pyramid in the medulla oblongata the component fibres cross to the opposite side, decussating with those of the corresponding bundle of that side and ascending in the pyramid of the opposite side (vol. i. p. 870); then passing forward through the pons, crus cerebri, and through the middle of the corpus striatum, they end in perikaryons in the cerebral cortex. These cortical cells are closely linked together by numerous commissural and association neurones, to be described hereafter. By these fibres the cortex cerebri is brought into relation with the voluntary muscles, there being but two interruptions in the circuit. (2) Other axons, ending about the same group of anterior horn cells, pass across at once to the opposite side of the spinal cord, and then ascend in the mesial part of the white tract bordering the ventral fissure. They run up in the pyramid of their own side, and otherwise follow a course comparable with those of the last set. These make the *direct pyramidal tract*. (3) A wide curved band of white spinal cord substance stretches from the outside of the direct pyramidal tract outside, and in front of the ventral horn, as far as the edge of the crossed pyramidal tract. This consists of the axons of shorter neurones, which begin in nerve-cells in the grey matter of the cord at different levels. Some of these axons cross in the anterior commissure to the opposite side, while others pass down in this tract to end by synapsis with the dendrites of the cells of the ventral horn thus, although this *ventrolateral association tract* is apparently a continuous mass, it is made up of shorter and more varied axons than the foregoing. These three tracts agree in being descending tracts coming from nerve-cells on a higher level and in being connected with the ventral horn-cells by synapses, and thereby with the motor nerve roots arising from them. (4) Two groups of axons, mostly ascending, are closely related to these, and spring from the cells of the lateral cell column of Clarke (vol. i. p. 866), whose dendrites are contiguous with those of cells in the ventral part of the column. These axons form a thin layer on the lateral surface of the cord between the dorsal and ventral nerve roots, and they extend on the same side into the restiform body of the medulla oblongata above, by which they pass into the cerebellum. By this *cerebellar tract* the neurones of the cerebellum are associated with the spinal nerve system; and it has been inferred from experiment that these are connected, in some way as yet unknown, with the co-ordination of muscular actions. (5) From the cells of the ganglia above described, which form the segmental origins of the sensory fibres constituting the dorsal roots of the spinal nerves, we have already seen that T-shaped processes arise. The inner branch of each of these passes centripetally, and forms the link between the ganglion of the root and the spinal cord. The continuations of these form almost all the white matter that lies internal to the dorsal roots. Most of these fibres run upwards, but some descend to form synapses with dorsal horn-cells on a lower level. These send, as they pass along, collateral branches into the grey matter of the dorsal horn to end around the nerve-cells there. Neurones of this grey matter in turn send axons, which terminate above in tufts about the cells of the posterior columns of the medulla oblongata, and these again send axons in the fillet of the crus cerebri, to end, after interruptions in the thalamus, in tufts about some of the smaller, deeper cells of the cerebral cortex. Thus the effect of an efferent impulse, while for the most part propagated upwards, may be to some extent continued downwards, sometimes causing reflex action by affecting the region below it. By means of these bundles of fibres in the cord, the segmental

nerves are linked together and so controlled as to act as component parts of a functional whole (Fig. 7).

The spinal cord is essentially bilateral. In the embryo it is formed of the lateral thickenings of the sides of the neural canal, and no neuroblasts (embryonic nerve-cells) arise either in the ventral or dorsal median portion of the wall of the canal. Whatever fibres at a later stage cross from side to side are invasions from lateral structures.

The *medulla oblongata* or *bulb* is developed from the

Fig. 7.—Diagram of the connexions of the motor and sensory nerves with the nerve centres. 1, Descending axons from the perikaryons of the motor centres in the cerebrum, decussating in the bulb, and united synaptically to the motor neurones in the cord; 2, axons which descend without decussating until they reach the level of the motor neurones, then crossing on the anterior white commissure of the cord; 3, associative neurones; 4, associative neurones connected with the cerebellum; 5, ascending axons from sensory cells, interrupted at the bulb; 6, ascending axons to cerebellum, ending by synapsis with associative neurones which connect cerebellum with cerebrum (9); 7, optic fibres from neurones in retina which connect cerebellum with cerebrum (9); 8, optic fibres from the optic thalamus; 9, optic fibres from the optic thalamus; CR, crus cerebri; DG, ganglion of dorsal root; SEN, sensory nerve.

wall of that part of the neural canal which formed the hinder cranial vesicle, and lies immediately within the foramen magnum of the skull. In it the dilated **Brain.** neural canal forms the fourth ventricle, which dorsally is for the most part closed by a membrane, the superior medullary velum, as well as by the cerebellum. Through the medulla pass the ascending and descending axons of the various cerebro-spinal association systems. In it are also the segmental nuclei of the nerves of the series of nine hinder cranial segments, which have become secondarily grouped into the V.-XII. nerves of Human Anatomy. The *cerebellum* (vol. i. p. 871) lying on the dorsal side of the ventricle has originated by two lateral ingrowths derived from

the tissues on either side, which ultimately fuse in the medio-dorsal line. With the neurones of this body the cerebellar tracts of the cord and several other series of association fibres passing to the mid-brain and thalamus are connected. The *mid-brain*, lying in front of the bulb, is the thickened wall of the second cranial vesicle (Fig. 7, sylv.), which in man has contracted into a canal, the *aqueduct of Sylvius*. Its thickened floor is the *pons Varolii*, mostly made up of—(1) commissural cerebellar fibres crossing from side to side, traversed longitudinally by (2) bundles of the descending fibres of the pyramids passing between the cerebrum and the spinal cord. These longitudinal fibres pass forwards on each side from the hemisphere to the pons, forming a large part of the *crura cerebri*. (3) Between the bundles of fibres are many nerve-cells, with which some of these fibres are directly and synaptically connected. In the ventral floor of the canal in this region are the segmental nuclei of the third, fourth and part of the fifth nerve. The relations of the nerve roots to the cranial vesicles show that the latter are not primitive morphological features, but only secondary mouldings of the brain mass superinduced after the fusion of the original segments of the cephalic region. The *quadrigenal bodies*, which in the human brain form the dorsal wall of the second cranial vesicle, are condensations into one irregular mass of several organically distinct series of neurones and their processes connected directly or indirectly—(1) with ascending axons from the dorsal roots of the spinal nerves, (2) with the wall of the anterior cranial vesicle, and (3) with the optic nerves. The original cavity of the fore-brain or anterior cranial vesicle becomes in the adult the *third ventricle*. Its side walls are thickened and form grey masses, the *optic thalami*. Its roof is membranous and contains no neurones, forming the *velum interpositum*. Median pouches of this cavity project—(1) upwards and backwards, and (2) downwards and forwards. The former has at its end the *pineal gland* or *epiphysis*, the vestige of a median eye, which is functional in *Sphenodon* and a few other reptiles; the latter, which is named the *infundibulum*, projects towards the *sella turcica* or fossa above the body of the sphenoid, and there thickens to form the posterior lobe of the *hypophysis*, or *pituitary body*. This thalamic region is apparently related to the segment of the head which originally bore the eyes. The front of the fore-brain is a membranous area, the *lamina terminalis*.

The part of the brain which lies above and in front of the thalamic region is the *cerebrum* (vol. i. p. 872), whose enormous growth in the higher mammals has caused it to overlap and alter the relations of the neighbouring parts of the brain. Its structure presents many obscure and difficult points, especially in the higher mammalia. The cerebrum consists of two hemispheres, originally separate from each other. These are at first hollow outgrowths from the upper, anterior, and lateral angle of the fore-brain, containing evaginations of the third ventricle, which are called the *lateral ventricles*. These communicate with the parent ventricle by an aperture, the *foramen of Monro*, in front of which is the *lamina terminalis*. The composition of the wall of the cerebral hemisphere can only be understood by a careful comparative study of its ontology, traced from the lowest vertebrates to the highest mammals (Fig. 8). In the former this wall of the hemisphere on the medial aspect, in front of the *lamina terminalis* and above it, consists of—(1) a grey area, the *corpus paraterminalis*. Above this a faint line of demarcation (*sulcus limitans*) maps out (2) a second area, the *hippocampus*, which in some lowly-organized mammals forms the entire of the remaining part of the medial wall of the hemisphere. On the outer wall above there is (3) a definite area, the *pallium*, very

small in lower vertebrates, enormous in the higher mammals. This is limited below and laterally by a *rhinal fissure*, which marks off (4) the *rhinencephalon*, or smell area, that makes up the rest of this wall. Above, the pallium extends to the margin of the hemisphere, where it is conterminous with the hippocampus. The floor of the hemisphere consists of (5) a grey mass, the *corpus striatum*, in front of which projects (6) a lobule, the *olfactory bulb* and pedicle, the latter of which often extends backwards, spreading around the corpus striatum to touch the paraterminal body and hippocampus on the inner side, and to form a *pyriform lobe* on the outer side, separated by the rhinal fissure from the pallium. All these parts in front of the rhinal fissure are included in the name *rhinencephalon*. Between the two hemispheres, as they grow, commissural neurones arise and send their axons across in the substance of the *lamina terminalis*,

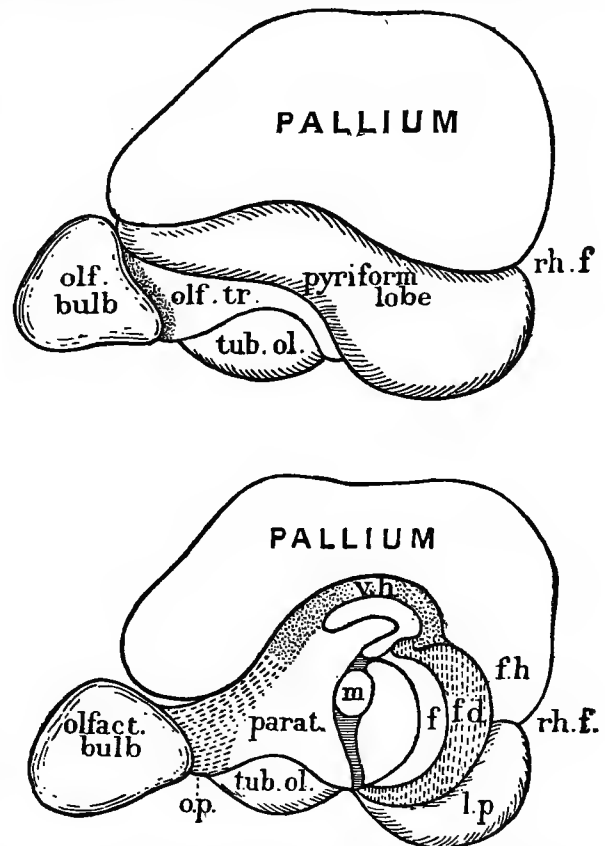

FIG. 8.—Scheme of the mammalian cerebral hemisphere. A, Lateral aspect. *rh. f.*, rhinal fissure; *olf. tr.*, olfactory tract; *olf. bulb.*, olfactory bulb; *tub. ol.*, olfactory tubercle. B, Medial aspect. *a. h.*, vestigia hippocampi; *f. h.*, hippocampal fissure; *f. d.*, fascia dentata; *f.*, fimbria; *l. p.*, pyriform lobe; *parat.*, paraterminal body; *m.*, foramen of Monro; *o. p.*, olfactory peduncle.

linking together the hemispheres. These become grouped in two bundles—one a dorsal commissure, the *fornix* or *psalterium*, which joins together the two hippocampal areas, and which in higher forms consists of longitudinal as well as transverse fibres. The other is ventral, and its fibres cross the basal region and rhinencephalon, consisting among others of the commissural fibres of the pallial area. In some animals a third commissure, the *commissura aberrans*, crosses the roof of the third ventricle behind the foramen of Monro (not to be confounded with the *commissura mollis* of an adult human brain). In such animals the roof of the third ventricle consists of the *velum interpositum*, a delicate epithelial layer attached on each side to the ventral lip of the paraterminal bodies. The lateral margins of this project into the foramen of Monro and constitute choroid plexuses.

These are, therefore, not parts of the wall of the hemisphere but of the fore-brain, and behind them is the aberrant commissure, which separates the choroid plexus from the membranous roof behind it (*paraphysis*), and lies at the caudal end of the paraterminal body. Behind the paraphysis is the commissure of the habenula in front of the pineal eye.

The predominant characteristic of the brains of man and of the higher mammals is the enormous overgrowth of the pallium, which consists of those neurones that govern the lower mechanisms and whose functions are to initiate actions. Coincidentally with this growth, remarkable changes take place in the other areas of the cerebral surface. The hippocampus becomes indented by the development of a longitudinal sulcus on its median aspect, and is differentiated in structure from the surrounding parts by the formation within it of a compact layer of pyramidal cells. The bottom of this sulcus projects into the lateral ventricle, and there makes a swelling to which the name hippocampus is often limited, while the part containing the column of cells at the margin of the hippocampal area which still remains on the median surface of the hemisphere close to the paraterminal body is called *fascia dentata*. These pyramidal cells are probably receptive cells connected with the olfactory nerve fibrils. The growth of the pallium towards the paraterminal body pushes the hippocampus backwards and causes its anterior end to become rudimentary, a mere pre-commissural vestige of the part which in the reptile and amphibian made up almost the whole mesial and part of the lateral wall of the hemisphere. With this enormous growth of the governing mechanism of the pallium there is correlated a growing necessity for bilateral co-operation, and therefore an increased growth of commissural neurones. But the space through which the original pallial commissural axons (in the ventral commissure) pass is limited by the growth of the ganglionic masses of the corpus striatum and their approximation to the thalamus (wall of the fore-brain). These new axons must therefore seek a new and more direct path, and they find this along the track occupied by the fibres of the now much reduced dorsal commissure. This newly-developing pallial commissure or *corpus callosum*, which is peculiar to the eutherian brain, is quite distinct from the hippocampal dorsal commissure, whose place it to some extent takes, and which it exceeds in size in proportion to the predominance of the pallium over the hippocampus. A portion of the paraterminal body is intercepted between the corpus callosum and the fornix, becoming the septum lucidum (vol. i. p. 876), which is thus not pallial but paraterminal in its nature. A fissure which runs from the margin of the olfactory bulb to the genu of the corpus callosum is the real boundary of the pallium, and the band which borders this furrow above, the gyrus sub-callosus, is also a surviving part of the paraterminal body. The ventral commissure, which continues to carry the uniting axons of the pyriform tubercle and olfactory bulb, is separated in the human brain by the anterior commissure. From these the pallial fibres which accompanied them in the marsupials as the most dorsal band of the ventral commissure have in the eutheria followed in their increase a course of least resistance and occupied the space vacated by the recession of the hippocampi. This change is foreshadowed in the brains of diprotodont marsupials by the separation of this band of the anterior commissure from the rest and its passing to the pallium through the internal capsule, as if to relieve the tension of the area of the anterior commissure.

The convolutioning of the surface of the adult cerebral hemisphere has been described at length in vol. i. p. 873. These convolutions are folds produced by the enormous growth of the grey surface of

the pallium, and first appear about the fourth month of foetal life. Arnold and others have described a series of transitory fissures which they supposed to arise and to become obliterated before the growth of the permanent set, but these have been shown to be the result of accident and reagents by Hochstetter and Elliot Smith. (For further particulars concerning the cerebrum see Cunningham, *Trans. Royal Irish Acad.* 1892, and the numerous papers in the *Journal of Anatomy* by Elliot Smith, 1898-1901. For the visceral nerves and their courses see Harman's papers, *Journal of Anat.* 1898, 1899, 1900. For views as to the general constitution of a nerve see Gaskell, *Journ. of Physiol.* 1886. For the distribution of sensory nerves see Head, *Brain*, 1893-94. The anatomy of the sense organs has been sufficiently treated in *Ency. Brit.* vol. i. pp. 884-899. An excellent account of recent work on the subject is given by Schäfer in *Quain's Anat.* iii. 1894.)

IV. *Organs of Assimilation.*—From appearances presented in the early stages of the vertebrate embryo, it is probable that there were two preceding forms of alimentary canal which were functional at different periods in the archaic ancestry of the group before the evolution of the existing or hypoblastic digestive organs. Of the earlier a vestige remains in the central canal of the spinal cord; of the second the notochord is possibly a trace. When the hypoblastic digestive canal becomes closed in, it has at first no communication with the outer surface, being closed both at the head and tail ends; but within the first few weeks of existence two superficial pits form, one on the ventral side of the fore-brain region and one on the ventral side of the tail. These, too, by the rupture of the membranes which separate them from the gut become respectively the mouth and the cloacal opening. The former of these pits is called the *Stomodæum*, and gives rise to the cheeks and lips, the alveolar arches, and the nasal passages. In it the palate arises as a horizontal partition, which grows from each side across its cavity, dividing the nasal from the oral cavity. Sometimes this partition fails to unite with its fellow in the middle line, giving rise to the malformation called cleft palate. The bottom part of the pouch of the stomodæum projects through the tissue which is forming the base of the skull, and fuses with the hypophysis to form the pituitary body.

The *pharynx* (see vol. vii. p. 222) is the part of the alimentary canal which lies in front of the continuous cœlomic cavity, having on each side of it the *Mouth*, remains of the primitive upper aortic arches, which in man have become the carotid arteries. It was in early embryonic life the region of visceral clefts like those which persist in fishes, but these disappear in man, except the first, which remains as the outer ear passage and the Eustachian tube. The *teeth*, described in vol. vii. p. 232, are papillæ of the same order as those of the skin, only differentiated because they are more discrete, larger, and arise on the dermis covering the jaw arches. Investigators are not agreed as to the nature of heterodontism—some (Osborn and Cope) teaching that the multituberculate molar has originated from the development of secondary tubercles on an originally simple protocone. Others, like Röse, believe the compound teeth to arise from the fusion of several papillæ. The balance of evidence is in favour of the latter view. Some mammals, such as the porpoise and other toothed whales, have but one dentition of homodont teeth; these are all animals with long narrow jaws and simple dental papillæ. In others, which are heterodont, all the first set persist together with several premolars of a secondary set. In others the milk set of teeth are replaced; but the permanent molars, which are the latest part of the primary dentition, persist and are not replaced, as in man. Man is descended from mammals which had three incisors on each side of each jaw, and three premolars. In all the primates, however, the lateral incisor has aborted, leaving only two; and likewise the hindmost of the premolars has generally

vanished, although a rudimental tooth in this position has been described by Fraser as a not uncommon anomaly among black races (*Proc. Camb. Philos. Soc.* 1900). In the lower races of mankind the teeth are large, and this can be measured by the comparison of the length of the five molar teeth with that of the basicranial axis. The former is over 44 per cent. of the latter in the black races; under 42 per cent. in the whites. The human soft palate has a *uvula* (vol. vii. p. 223), which is absent in most mammals. This pendant acts as a sentinel at the passage from the mouth to the pharynx, and is needed because of the upright position of man and because in him the glottis, or top of the air passage, is not prolonged up so as to project into the nasal region of the pharynx above the velum, as it is in the majority of animals.

Concerning other parts of the digestive canal, further research on the œsophagus will be found in the papers of Birmingham, *Journal of Anat.* xxxiii. p. 10, and Strahl, *Arch. f. Anat. u. Phys.* 1889. For the minute structure of the stomach, see Langley, *Journal of Phys.* 1882, and Müller, *Verhandl. d. biol. Verein.* Stockholm, 1891-92. For a discussion on the position of the stomach, see Lesshaft in Virchow's *Archiv*, 1882. On the cæcum see Treves, *Hunterian Lectures*, 1885. Recent descriptions of the structure of the villi of the small intestine will be found in Paneth, *Arch. f. mikroskop. Anat.* 1888; and on the study of the pancreas see Podrwyssotzky, *Arch. f. mikroskop. Anat.* 1882. The lobes of the liver and their embryonic relations have been described by Thomson, *Journ. of Anat.* xxxiii. p. 546; on the structure of the liver see Retzius, *Biol. Untersuch.*, Stockholm, 1892, and Shore, *Journ. of Physiol.* 1889.

In the foetal intestine the duct of the umbilical vesicle communicated with the region which becomes in the adult the lower part of the small intestine. In general it disappears completely, but occasionally the terminal part of the duct persists as a short blind tube which is called *Meckel's diverticulum*. The differentiation of the lower end of the alimentary canal as a large intestine begins in the lower vertebrates. That part which in the quadruped is lowest and most depending becomes distended by the accumulation of waste or faecal materials, and when this differentiation is established, the

FIG. 9.—Cæcum and vermiform appendix of human intestine.

beginning of the large gut is usually marked by the development of a blind pouch or *cæcum*. In the human embryo this is a tapering conical sac, but when, after the assumption of the upright position, the cæcum changes its position and sinks down on the right side into the iliac fossa, the base of this becomes distended and is called the cæcum, while the originally fusiform extremity narrows and becomes the *vermiform appendix* (Fig. 9), often the seat of a painful and dangerous inflammatory process—another of the penalties we pay for the advantage of the upright position.

A series of peculiar glandular masses in the body differ from the true secreting glands in having no separate ducts. It is generally believed that these pour their secretions directly into the blood, and it is certain that in most cases disease or ablation of these organs produces specific effects on the composition of the blood and on local nutrition. These organs are (1) the *spleen* (vol. i. p. 907), whose essential structure (Fig. 10) consists of a mass of adenoid connective tissue, with a fibro-muscular capsule, into whose meshes capillary and other blood-vessels open (a good description of its tis-

sue is given by Klein, *Quart. Journ. of Micros. Sc.* 1875); (2) the *thyroid* body, which arises as a diverticulum from the fourth branchial cleft on each side and medially from the fundus of a pouch whose opening remains in vestige on the back of the tongue, as in the *foramen cæcum*. It consists essentially of a number of closed follicles lined with epithelium, embedded in a vascular connective-tissue matrix (see Baber, *Phil. Trans.* 1876; Biondi, *Archiv. Ital. de Biol.* 1892). (3) Embedded in the thyroid are the *para thyroid* bodies, of which there are two on each side, differing in the details of structure from the thyroid (see Welsh, *Journ. of Anat.* xxxii. 292). (4) The thymus, transitory in man, but persistent in other animals, is derived from a diverticulum of the third branchial cleft (see Watney, *Phil. Trans.* 1882; and Symington, *Journ. of Anat.* xxxii. 278). (5) The *suprarenal body*, placed above and on the inner side of the kidney. (For its structure see Rolleston, and for the development, Minot, *Embryology*, p. 485.) (6) The *pituitary* body above the body of the sphenoid is formed partly from the end of the infundibulum of the brain and partly from the fundus of the stomodæum. For its structure see Schöne-mann in Virchow's *Archiv*, 1892. Other structures of the kind which are rudimentary in man are (7) the *carotid gland*, and (8) the *coccygeal body*. (Described by Luschka, Virchow's *Archiv*, 1860; Reichert's *Archiv*, 1862; and Schaper, Schultze's *Archiv*, 1892. See also Arnold, Virchow's *Archiv*, 1866.) The *hæmolymp glands* which lie in the hilum of the kidney are also structures of this class. (See Drummond, *Journ. of Anat.* 1900.)

V. The *vascular system* has been described in vol. i. p. 899, and most additions to our knowledge have been in matters of detail. The development of the heart has been revised by Born. The morphology of the venous system has been carefully studied in detail by Hochstetter (*Anat. Anz.* 1887-88; *Morpholog. Jahrb.* 1891). For the arterial system see Eichholz in *Journ. of Anat.* 1895, and Mackay, *Proc. Philos. Soc. Glasgow*, 1887. The histological elements of blood are described in vol. i. p. 845. It has since been shown that white corpuscles do not constitute a homogeneous category, but under this name at least six diverse forms are present in healthy blood. The points of difference are size, shape, and disposition of nucleus; nature of cell reticulum; and composition of the contained granules as shown by their different reactions with staining media. The following are the chief varieties:—

(1) About 70 per cent. of the corpuscles have polymorphic, many-lobed nuclei which often seem to break up into three or four distinct masses (hence these have been named *polynuclear*). The cells are moderately large and stain readily, the protoplasm reacting to acid stains while the granules are neutrophile. (2) About 2 per cent. of corpuscles, similar to the last in most aspects, differ by containing a peripheral stratum of granules which stain deeply with eosin. (3) About 1 per cent. are mononuclear, of much larger size, the single nucleus being large, oval, and excentric; the protoplasm is free from granules and weakly basophile. (4) About 4 per cent. of the total are intermediate in characters between those of the first and third orders; they are smaller than the typical mononuclear leucocytes, and have a bilobed nucleus which stains more

deeply than that of the last group. Neutrophile granules are sparingly present in the protoplasm. (5) A very small number (less than 0.5 per cent.) are sharply marked off from the first order by possessing intensely basophile granules unequal in size and irregular in distribution; when acted on by certain stains they exhibit tints characteristically different from those which the same stains produce in other corpuscles. (6) Lymphocytes (about 23 per cent.) are bodies quite distinct from any of the foregoing orders. They are small, about the size of red corpuscles, and contain a large round nucleus, marked as if made of concentric layers, and staining uniformly. It is surrounded by a thin protoplasmic layer whose reticular structure is easily brought out by basic stains. The discrimination of these various forms and their abnormal modifications is regarded as important in modern pathology (see Ehrlich-Lazarus, *Anæmie*. Vienna, 1898, pt. 1).

VI. *Eliminative Organs.*—The urinary and reproductive organs are inseparably united in man as in all vertebrates. The former consist of the *kidneys* and their ducts—the *ureters*, the *urinary bladder*, and the *urethra*. The latter, in the male, of the *testes*, *vesiculæ seminales*, *vasa deferentia*, and the *prostatic and anteprostatic glands*. In the female the organs are *ovary*, *Fallopian tube*, *uterus*, and *vagina*, and the several folds which bound the vaginal opening. There is embryological evidence that the kidneys are specialized organs which have originated at a comparatively late period of vertebrate phylogeny. In the elementary condition of urogenital organs found in segmented invertebrates the sex-gland is only a specialized area of the lining epithelium of the coelom (vol. xx. p. 408), and the sex-products, ova or spermatozoa, arising from the germinal epithelium are shed into the body cavity. A communication between the body cavity and the surrounding medium exists in the form of a segmental tube or nephridium on each side of each segment. These are not only the channels of escape of the sex-products, but are also, in general, excretory organs. In the earlier stages of the lower vertebrates the presence of segmental nephridia can be demonstrated, one portion, a head-kidney or pronephros, arising in some of the anterior segments, and a second, or mesonephros, in the segments at a level farther back. These segmental tubules open internally into the coelom and outwardly into a lateral canal which runs longitudinally and ends posteriorly by opening into the cloaca. The longitudinal tube connected with the pronephros is known as the pronephric or Müllerian duct, that connected with the mesonephros or Wolffian body is named the mesonephric or Wolffian duct. In man, as in all the amniota, there arises at an early period of development a third group of nephridial tubules, the metanephric, which by their aggregation make up the metanephros or kidney. That these are the result of a high degree of specialization is obvious from the fact that, while in the cases of the pronephros and mesonephros the nephridia and the longitudinal ducts arise independently and unite after they have attained a considerable degree of development, in the metanephros the tubules are from the first offsets from the metanephric duct or ureter, which itself arises as an offset from the mesonephric duct. In man there is never any trace of a pronephros, but the pronephric duct is distinct. The mesonephric tubules rapidly lose all traces of their secreting portions, and appear only as a vestigial structure, rudimentary in the female; but they become in the male specialized as channels for the transmission of the sex-products. The *kidneys* are two bean-shaped granular masses, firm in consistence and reddish-brown in colour, about $4\frac{1}{2}$ inches long, and placed obliquely behind the other abdominal viscera—one on each side of the last thoracic and three upper lumbar vertebræ. Each is imperfectly covered on its ventral surface by peritoneum, and is moulded to some extent by the viscera which press on it. Around them there is usually a considerable amount of fat and areolar tissue, by which as well as by the peritoneum and by the

presence of the surrounding viscera, the kidneys are retained in their place. In rare cases the kidney may slip from its usual place in the loins to a lower position, and may even be movable in the abdominal cavity—a condition often productive of serious consequences. The *Kidneys.* The kidney in the fœtus is lobulated, but the intervals between the lobes become smoothed out in later years of childhood. Each gland is invested by a firm, closely-adherent, fibrous capsule, under which is an imperfect lamina of unstriated muscle. The inner and ventral margin of each kidney is concave, and into this *hilum* or concavity the renal artery from the aorta passes. Here also the renal vein escapes and joins the vena cava inferior. The ureter or metanephric duct, always behind and below the blood-vessels, emerges here and passes backwards to the bladder. When the kidney is longitudinally divided from hilum to outer edge, the cut surface is seen to consist of two parts—an outer cortical layer, and an inner or medullary mass (Fig. 11). The latter consists of a series of eight to sixteen

FIG. 11.—Vertical section through the kidney. A, branch of renal artery; U, ureter. 1, cortical substance with cortical pyramids, and labyrinth substance of tortuous tubes; 2 and 3, medullary pyramids of straight tubules; 4, fatty masses around blood-vessels (5); 6, papilla; 7, pelvis.

pyramids, whose bases and sides are invested with cortical matter and whose apices or papillæ project into the hilum, where they are severally surrounded by membranous tubes (calyces), which by their union make up the ureter. The part of the ureter situated in the hilum is dilated, and is named the pelvis of the kidney.

In minute structure the kidney is the most complex gland in the body. Each of the papillæ consists of a large number of straight tubes which open by pores on its surface. When these are traced into the pyramid they are seen to divide several times, their fine end-branches projecting in little tufts into the cortical matter at the base of each pyramid. Here the branches coming from the tube change in structure and become convoluted in the cortex. Next, each suddenly dips back again as a long straight loop into the pyramid, reaching nearly to the papillary region; then turning sharply on itself, passes back straight to the cortex, where it again becomes convoluted, ultimately ending by dilating into a flask-like bulb. The renal artery, after breaking up into branches

between the pyramids, ends in minute end-arteries in the cortex. Each of these pierces into one of the flasks just described, and there becomes branched, the branches being collected into a little ball or glomerulus which nearly fills the flask. From this an efferent vessel escapes, which, joining with its neighbouring vessels of the same kind, makes a close network around the convoluted tubes, ultimately ending in the renal vein. It is supposed that the different constituents of the urine are eliminated in different parts of these tubes—some, especially the watery parts, in the flask, and some, especially the more solid constituents, in the convoluted tubular apparatus. A peculiar form of glandular epithelium lines the two convoluted areas of the tubes, and the limb of the loop nearer the straight or collecting tubes.

The *ureter* or duct of the kidney begins at the hilum and descends on the back wall of the abdominal cavity to open into the bladder. It is usually about 12 inches in length and as thick as a goose quill. At its termination it passes obliquely through the coats of the bladder, so that when the bladder is distended the lumen of its end is closed. The *urinary bladder* is a membranous bag lying in the pelvic cavity directly behind and above the dorsal surface of the pubes. In the fœtus and infant, however, the bladder lies in the abdomen, not in the pelvis. During life it is seldom distended so as to hold more than about 10 oz., but when the abdomen is opened it can be dilated to more than double that size. When distended it rises and is applied closely against the back of the ventral

Bladder and urethra.

Fig. 12.—Vertical section through pelvis, showing urinary bladder and rectum *in situ*. 1, peritoneum; 2, pubic symphysis; 3, muscular coat of bladder; 4, mucous membrane folded and wrinkled; 5, opening of ureter; 6, prostate; 7, vena dorsalis penis; 8, corpus spongiosum; 9, testis in its sc; 10, bulbocavernosus muscle; 11, bulb; 12, sphincters of the anus; 13, anal opening; 14, coccyx; 15, vesicula seminalis.

abdominal wall. The bladder has a strong muscular investment of unstriped muscle in several layers, which are innervated by branches from the sacral nerves. It has a peculiar epithelial lining of several strata, the superficial cells of which are cubical when the sac is collapsed, but become flattened and scale-like when it is distended. The bladder is developed from the portion of the sac of the embryonic allantois, which is in contact with the cloaca. The two ureters open by small oblique apertures into its base, closely behind the opening of the urethra. The *urethra* or excretory channel from the bladder is a narrow tube, $8\frac{1}{2}$ inches long in the male,

whose walls are in apposition except when fluid is passing along it. It begins at the lowest part of the bladder and for its first inch and quarter passes through the prostate gland and is directed vertically downwards. The hinder wall of this portion is raised into a ridge, the *colliculus seminalis*, on each side of which the seminal ducts open. The second part is membranous, about $\frac{3}{4}$ inch in length, and directed forwards below the pubes, where it is fixed by passing through the triangular interpubic ligament. The third part is that which lies in the penis, and it is surrounded below and laterally by an erectile enveloping body, the *corpus spongiosum urethrae*. This body begins behind in a thickening, the *bulb* of the urethra, and ends in the *glans penis*, which is perforated by the urethra. Above the urethra in this stage lie the two *corpora cavernosa penis*. The urethral orifice is usually the narrowest part of the canal. The female urethra is only $1\frac{1}{2}$ inch in length, and is comparable only with that part of the male urethra which extends from the bladder to the openings of the seminal ducts (Fig. 12).

VII. *Reproductive Organs.*—In the human male these are the testes and their ducts, the latter being the modified mesonephric or Wolffian tubules and ducts of the fœtus. In the female they consist of the ovaries and the tubular system appended to them, which are formed from the modified Müllerian ducts. In each sex the tubular system which is not functional is represented in rudiment. Both ovary and testis are specializations of the area of germinal epithelium of the fœtal coelom. In the *ovary* these germinal cells become grouped in numerous

Female.

clusters, in the centre of each of which is a cavity, the *Graafian vesicle*, containing a central cell larger than the others, which is a *primitive ovum*. Each of these is about $\frac{1}{100}$ inch in diameter, and it has been computed that there are about 30,000 in each ovary of a female child at birth. These Graafian vesicles are embedded in a mass of connective tissue which is called the stroma of the ovary, the whole ovary being a small oval body about $1\frac{1}{2}$ inch long by about $\frac{1}{2}$ inch in thickness. The ovaries are placed one on each side in the pelvic cavity, each within a fold of peritoneum, called the *broad ligament*. Close to each ovary lies the open and fringed end of a duct, the *Fallopian tube*, which is contained in the upper edge of the broad ligament and directed inwards to open into the *uterus*. This is a pyriform organ lying in the middle of the pelvic cavity, having the bladder on its ventral aspect, the rectum on its dorsal, and the two broad ligaments one on each side. The uterus, when not containing a fœtus, is about 3 inches in length, nearly 2 inches in breadth, and 1 inch in thickness. It has a very thick wall, mostly made up of unstriped muscle, and a very small cavity which appears somewhat triangular in vertical section. Its lateral basal angles are at the openings whereby the Fallopian tubes communicate with it, and its apical inferior angle is at the neck or *cervix uteri*. This cervix projects into the upper part of the vagina, which is a membranous passage that opens on the surface. The uterus and Fallopian tubes are modifications of the Müllerian ducts and of the part of the cloaca into which these ducts open. The vagina and the folds which surround its external opening are the modifications of the urogenital sinus and its marginal folds to be referred to below.

The ova are during mature life periodically shed by rupture of the Graafian follicles when these become ripe. These are received into the open mouths of the Fallopian tubes, by which canals they are conducted into the uterus, where if fertilized they develop, but if not fertilized they are extruded. Before fertilization each ovum undergoes a process of cell division by which it extrudes a portion of its nuclear substance and particularly a portion of its

chromosomes. The act of fertilization consists in the reception by the ovum of certain nuclear masses, including chromosomatic substance, which unites with the nuclear substance and chromosomes of the ovum to form a new complete nucleus.

The *testis* or male sex gland is also developed from the germinal area of the coelom. Nests of cells derived from the germinal epithelium become clustered and surrounded with a stroma of mesoblast into which the Wolffian tubules penetrate, ultimately becoming a tubular system, whose terminal roots enclose the cell nests as a

Male. lining epithelium. When first formed the testes lie in the lumbar region of the foetal abdomen above and internal to the kidneys, but from this site they begin to migrate about four months before birth. They reach the abdominal wall in the groin in two months, and there each passes through an oblique canal (the *inguinal canal*) in the muscular and fibrous wall of the abdomen and descends into the scrotum, which is a loose bag of skin formed by the lateral lips of the urogenital sinus (which long before this period have united medially). This descent is generally completed a month before birth. Along with the testis a tubular pouch of the serous lining of the abdomen is prolonged into the scrotum, which, when the descent is complete, becomes obliterated at the place where it traverses the abdominal wall, though remaining below as an envelope of the testis. The region of the inguinal canal is always the weakest spot in the abdominal wall, and it is along the track of the descended testis that those protrusions of the abdominal viscera, called *herniæ*, are most liable to occur. As it is the assumption of the upright position which places the inguinal canal at the lowest part of the abdomen, this tendency to hernia is another of the penalties which man pays for the advantages of a bipedal progression.

The testis in the adult is made up of a great mass of convoluted tubules arranged in about 200 lobules, and the whole mass is included in a tough fibrous tunic. The lining epithelium of these seminal tubes by a special method of cell division gives rise to the male elements or spermatozoa, which are minute thread-like bodies consisting of a small oval head, about $\frac{1}{5000}$ th inch long, a slender middle-piece nearly as long, and a hair-like flagellum or tail tapering to a fine point and measuring $\frac{1}{500}$ th inch. The tubular system whereby these and the fluid in which they float are conveyed away is derived from the Wolffian tubules, which open into the Wolffian duct, now called *vas deferens*. Owing to the new position assumed by the testis, this duct has to ascend from the scrotum, to pass through the inguinal canal, and then to descend into the pelvic cavity in order to gain the first part of the urethra, into which it opens. Close to the urethral extremity of each *vas deferens*, and on its outer side, is an irregularly pyriform pouch, the *vesicula seminalis*, to store the secretion from the testis.

In early foetal life the terminal openings of all the excretory tubes—intestinal, urinary, and genital—unite and reach the surface by a single slit-like orifice. This condition, which is persistent in the monotremata and lower vertebrates, is transitory in man and the higher mammals. When first formed, the hinder end of the gut, with its appended allantois, has no external aperture, but at an early date in the embryonic history a pit of the surface integument, which is named the *proctodæum*, dips in on the ventral side of the vertebral column, and its bottom layer comes in contact with the gut close to its extreme blind end. Soon the membrane separating this pit from the gut ruptures, and the *cloaca* is formed. During the second month of foetal life a transverse ridge, formed by a

downgrowth of the ventral wall of the lower end of the gut, shuts off the allantois from the intestine and divides the cloaca into a ventral or *urogenital region*, and a dorsal or *anal*. By the third month this partition has thickened into a definite band of integument which is called the *perinæum*. The urogenital sinus is a slit-like space into which open the allantois, the Wolffian and Müllerian ducts and the ureters. At the ventral end of its aperture an eminence, the *tuberculum genitale*, rises, deeply grooved on its dorsal surface; and from the lower edge of each lip of the groove a marginal *vestibular ridge* descends on each side of the opening of the sinus to unite with its fellow at its dorsal extremity. On each side, external to this vestibular ridge, the skin at the margin of the urogenital sinus forms a prominent lip, making the opening appear as a longitudinal fissure. So far the process of development is identical in the two sexes, but at this point differentiation occurs. In the female the tuberculum genitale becomes the clitoris, and the vestibular and marginal folds respectively the labia majora and minora. In the male the vestibular folds unite in the median line, except at their ventral extremity, thus closing in the canal which forms the second and third parts of the urethra, and in the combined under-wall thus constituted erectile tissue develops, forming the corpus spongiosum urethræ above described. The terminal ventral opening becomes the meatus urinarius. The two cutaneous outer lips also fuse together medially, making the scrotum. The bilateral tuberculum genitale becomes by the development of erectile tissue the corpora cavernosa penis. In each sex the tubular system which does not become functional leaves vestiges which discharge no function. In the female the Wolffian tubules remain as a series of linear streaks in the substance of the broad ligament, the *epoophoron*. In the male the Müllerian ducts leave two vestiges, a minute sacculæ appended to the top of the testis, and a minute pouch, the *sinus pocularis*, in the colliculus seminalis of the urethra. This latter corresponds to the cavity of the uterus in the female, a correspondence which is rendered more striking as this pouch and the adjoining portion of the urethra are surrounded by a mass of unstriped muscle, with some gland tubes included in it, to which the name *prostate* is given. This organ is about the size and shape of a chestnut.

Variability of the Human Body.

No two human bodies are alike in their organization, and there is no organ in the body which is not liable to vary. Some parts, however, are especially liable to abnormalities, more especially those which have the most complicated developmental history, those which derive their origin from more than one component, which pass through several stages and are late in arriving at their full development. Of those organs which occur in series, the terminal members are more variable than the intermediate. Organs do not vary indifferently in every direction; there are some conceivable forms of variety which never occur, others which are common. Nor can variations be reduced to a continuous series. Some of them are sudden breaks, between which and the normal no intermediate links are known.

Most varieties are individualistic, depending on conditions of nutrition or enviroing circumstances affecting development. A few, such as the development of a third incisor or third premolar, seem to be atavistic, but atavism has been invoked in many cases to which it does not apply. The vascular system is the most, and the nervous the least, variable. The muscular and skeletal systems occupy intermediate positions. The literature of anomalies is very large. The general subject is dealt with in the *Robert*

Boyle Lecture, Oxford, 1894; see also MONSTER (*Ency. Brit.* vol. xvi. p. 762) and Bateson, *Materials for the Study of Variation*, 1895.

History of Anatomy.—To the detailed history given in vol. i. pp. 799 *et seqq.*, it is only necessary to add that recent researches on the early history of anatomy will be found in the several articles entitled "Archæologia Anatomica" in the *Journal of Anatomy* for 1898, 1899, and 1900. (A. MA.)

Anatomy of Plants.

The term "Anatomy," originally employed in biological science to denote a description of the facts of structure revealed on cutting up an organism, whether with or without the aid of lenses for the purpose of magnification, is restricted in the present article, in accordance with a common modern use, to those facts of internal structure not concerned with the constitution of the individual *cell*, the structural unit of which the plant is composed. For a description of the cell itself, the article *CYTOLOGY* must be consulted. In all but the very simplest forms the plant-body is built up of a number of these cells, associated in more or less definite ways. In the higher (more complicated) forms the cells differ very much among themselves, and the body is composed of definite systems of these units, each system with its own characteristic structure, depending partly on the characters of the component cells and partly on the method of association. Such a system is called a *tissue-system*, the word *tissue* being employed for any collection of cells with common structural, developmental, or functional characters to which it may be conveniently applied. The word is derived from the general resemblance in the texture of plant substance to that of a textile fabric, and dates from a period when the fundamental constitution of this substance from individual cells was not yet discovered. The study of tissues is known as *Histology*, and it is with this that the present article is necessarily mainly concerned. The method of treatment will be evolutionary; that is to say, an endeavour will be made to trace the gradual steps through which the more complicated tissue-systems of the various groups of plants have been developed from simple cell-collections, during that descent of the more complicated from the simpler plants which constitutes the fundamental postulate of the comparative study of form in modern biology. The terms *morphology* and *morphological* will be used throughout wherever such comparative consideration with this evolutionary implication is involved. It must be understood, however, that the evolution of form is invariably governed by the vital needs of the organism, so that a consideration of the vital relations of the plant to its surroundings, and of the actions and functional relations of its organs and tissues, is an indispensable condition of the construction of a real and intelligible morphology. In this way our outline of *morphological* anatomy will involve an outline of *physiological* anatomy.

It will easily be realized that since the plant-body consists entirely of tissues, through which all its functions are performed, an account of the evolution of plant-tissues is nearly equivalent to an account of the evolution of plants. Our task will be simplified, however, by the omission of direct reference to the tissues of the specialized reproductive organs, for which the reader is referred to the articles on the different groups of plants. Even so it must be apparent that in the present article nothing but the barest sketch of the subject, in which much is left out and many topics are treated dogmatically, is at all possible. The articles *BOTANY* (*Ency. Brit.* vol. iv. pp. 85-93, and 99-108), and *HISTOLOGY, VEGETABLE* (vol. xii.), give good general accounts of the nature of vegetable tissues, particularly in the flowering plants, and in the former are many figures, for the most part admirable, illustrating histological

structure, which the reader may consult with advantage. Much of the terminology and some of the descriptions are, it is true, out of date, a result that must always soon occur in a very rapidly advancing branch of science, as plant anatomy was twenty years ago. The morphological point of view, as sketched above, has been fully applied to plant-tissues only in very recent years, so that in an article of earlier date it is only natural that the provisional nature of descriptive terminology should become very apparent after the lapse of a few years.

An account of the structure of plants naturally begins with the *cell*, which is the proximate unit of organic structure. The cell is essentially an individualized mass of protoplasm containing a differentiated protoplasmic body, called a *nucleus*. But all cells which are permanent tissue-elements of the plant-body possess, in addition, a more or less rigid limiting membrane or *cell-wall*, consisting primarily of cellulose or some allied substance. It is the cell-walls which connect the different cells of a tissue, and it is upon their characters (thickness, sculpture, and constitution) that the qualities of the tissue largely depend. In many cases, indeed, after the completion of the cell-wall (which is secreted by the living cell-body) the protoplasm dies, and a tissue in which this has occurred consists solely of the dead framework of cell-walls, enclosing in the cavities or *lumina* originally occupied by the protoplasm simply water or air. In such cases the characters of the adult tissue clearly depend solely upon the characters of the cell-walls, and it is usual in plant anatomy to speak of the wall with its enclosed cavity as "the cell," and the contained protoplasm or other substances, if present, as *cell-contents*. This is in accordance with the original use of the term "cell," which was applied in the 17th century to the cavities of plant-tissues on the analogy of the cells of honeycomb. The use of the term to mean the individualized nucleated mass of living protoplasm, which, whether with or without a limiting membrane, forms primitively the proximate histological element of the body of every organism, dates from the second quarter of the 19th century. We proceed to a systematic account of the anatomy of the different groups of plants, beginning with the simplest, and passing to the more complicated forms.

Thallophyta.

The simplest members of both the *Algæ* and the *Fungi* (*q.v.*), the two divisions of the *Thallophyta*, the lowest of the four great groups into which the plant-kingdom is divided, have their bodies each composed of a single cell. In the *Algæ* such a cell consists essentially of—(1) a mass of protoplasm provided with (2) a nucleus; and (3) an assimilating apparatus consisting of a coloured protoplasmic body, called a *chromatophore*, the pigment of which in the pure green forms is chlorophyll, and which may then be called a *chloroplast*. The whole is covered by the cell-membrane (Fig. 1 A). It is from such a living and assimilating cell, performing as it does all the vital functions of a green plant, that, according to current theory, all the different cell-forms of a higher plant have been differentiated in the course of descent.

Among the Green *Algæ* the differentiation of cells is comparatively slight. Many forms, even when multicellular, have all their cells identical in structure and function, and are often spoken of as "physiologically unicellular." The cells are commonly joined end to end in simple or branched filaments. Such differentiation as exists in the higher types mainly takes two directions. In the fixed forms, the cell or cells which attach the plant to the substratum often have a peculiar form, containing less chlorophyll, and constituting a rudimentary fixing organ or *rhizoid* (Fig. 1 C). In certain types living on damp soil, the rhizoids penetrate the substratum, and in addition to fixing the plant absorb food substances (dissolved salts) from the substratum (*Ædocladium*, Fig. 1 D).

Cell and tissue differentiation in Algæ.

FIG. 1.—EXAMPLES OF THE DIFFERENTIATION OF TISSUE IN PLANTS.

A, Cell (individual) of the unicellular Green Alga *Pleurococcus*, as an example of an undifferentiated autonomous assimilating cell. *pr.*, Cell protoplasm; *n.*, nucleus; *chl.*, chloroplast; *c.w.*, cell-wall.

B, Plant of the primitive Siphonous Green Alga *Protosiphon botryoides*. The primitive cell sends colourless tubelike (rhizoids, *rh.*) into the mud on which it grows. The subaerial part is tubular or ovoid, and contains the chloroplast (*chl.*). There are several nuclei.

C, Base of the multicellular filamentous Green Alga *Chatomorpha vesca*. The basal cell has less chlorophyll than the others, and is expanded and fixed firmly to the rock on which the plant grows by the basal surface, *rh.*, thus forming a rudimentary rhizoid.

D, Part of branched filamentous thallus of the multicellular Green Alga *Ectocladium protonema*. *or. ax.*, Green axis creeping on the surface of damp soil; *rh.*, colourless rhizoids penetrating the soil; *asc. ax.*, ascending axes of green cells.

E, Vertical section of frond of the complicated Siphonous Green Alga *Halimeda*. The substance of the frond is made up by a single much-branched tube, with interwoven branches. *cond. med.*, Longitudinally running comparatively colourless central (medullary) branches, which conduct food substances and support the (*ass. cor.*) green assimilating cortical branches, which are the ends of branches from the medulla and fit tightly together, forming the continuous surface of the plant.

F, Section through the surface tissue of the Brown Alga *Culleria multifida*, showing the surface layer of assimilating cells densely packed with phaeoplasts. The layers below have progressively fewer of these, the central cells being quite colourless.

G, Section showing thick-walled cells of cortex in Brown Alga (seaweed). Simple pits (*p.*) enable conduction to take place readily from one to another.

H, Two adjacent cells (leptoids) of a food-conducting strand in *Fucus* (a Brown seaweed). The wall between them is perforated, giving passage to coarse strands of protoplasm.

I, End of hydroid of the thaloid Liverwort *Pallavicinia*, showing the thick lignified wall penetrated by simple pits.

J, End of hydroid of the Moss *Anitum*, showing particularly thin oblique end-wall. No pits.

K, Optical section of two adjacent leptoids of the Moss *Polytrichum juniperinum*. The leptoids are living and nucleated. They bulge in the neighbourhood of the very thin cross-wall. Note resemblance to H and R.

L, Optical section of cell of conducting parenchyma in the same moss. Embedded in the protoplasm are a number of starch grains.

M, Part of elongated steroid of a Moss. Note thick walls and oblique slit-like pits, with opposite inclination on the two sides of the cell.

N, One side of end of hydroid (tracheid) of Pteridophyte, with ecdysiform pits.

O, Optical section of two adjacent leptoids (sieve-tube segments) of Pteridophyte, with sieve plates (*s. pl.*) on oblique end-wall and side-walls.

P, Part of spiral hydroid (tracheid) of Phanerogam.

Q, Three segments of a "pitted" vessel of Phanerogam.

R, Optical section of leptoid (sieve-tube segment) of Phanerogam, with two protoid (companion) cells. *s. pl.*, sieve-plates.

S, Optical section of part of thick-walled steroid of Phanerogam, with almost obliterated cavity and narrow slit-like oblique pits.

T, Part of vertical section through blade of typical leaf of Phanerogam. *u.e.*, Upper epidermal cells, with (*c.*) cuticle, (*p.*) assimilating (palisade) cells, *sp.*, Assimilating (spongy) cells, with large lacunae. *l.e.*, Lower epidermis, with *st.*, stomata.

U, Absorbing cell, with process (root-hair) from piliferous layer of root of Phanerogam.

V, Endodermal cell of Phanerogam, with suberized central bend on radial and transverse walls.

The second type of differentiation is that between supporting axis and assimilating appendages. The cells of the axis are commonly stouter and have much less chlorophyll than those of the appendages. This differentiation is parallel with that between stem and leaf of the higher plant. In the group of the Siphonæ both these types of differentiation may exist in the single, long, branched, tube-like, and multinucleate cell which here forms the plant-body. *Protosiphon* (Fig. 1 B) is an example parallel with *Ectocladium*; *Bryopsis*, with *Draparnaldia*. In *Caulerpa* the imitation of a higher plant by the differentiation of fixing, supporting, and assimilating organs (root, stem, and leaf) from different branches of the single cell is strikingly complete. In the Siphonous family of *Codiaceæ* (Fig. 1 E) the branches of the primitive cell become considerably interwoven one with another, so that a dense tissue-like structure is often produced. In this we get a further differentiation between the central tubes (branches of the primitive cell), which run in a longitudinal direction through the body, possess little or no chlorophyll, and no doubt serve to conduct food substances from one region to another, and the peripheral ones, which are directed perpendicularly to the surface of the body, ending blindly there, contain abundant chlorophyll, and are the assimilating organs.

None of the existing Red Seaweeds has a unicellular body. The thallus in all cases consists of a branched filament of cells placed end to end, as in many of the Green Algae. Each branch grows simply by the transverse division of its apical cell. The branches may be quite free or they may be united laterally to form a solid body of more or less firm and compact consistency. This may have a radial stem-like organization, a central cell-thread giving off from every side a number of short sometimes unicellular branches, which together form a cortex round the central thread, the whole structure having a cylindrical form which only branches when one of the short cell-branches from the central thread grows out beyond the general surface and forms in its turn a new central thread, from whose cells arise new short branches. Or the thallus may have a leaf-like form, the branches from the central threads which form the midrib growing out mainly in one plane and forming a lamina, extended right and left of the midrib. Numerous variations and modifications of these forms exist. In any case, while the internal threads which bear the cortical branches consist of elongated cells with few chromatophores, and no doubt serve mainly for conduction of food substances, the superficial cells of the branches themselves are packed with chromatophores and form the chief assimilating tissue of the plant. In the bulky forms colourless branches frequently grow out from some of the cortical cells, and, pushing among the already-formed threads in a longitudinal direction, serve to strengthen the thallus by weaving its original threads together. The cells belonging to any given thread may be recognized at an early stage of growth, because each cell is connected with its neighbours belonging to the same thread by two depressions or pits, one at each end. The common wall separating the pits of the two adjoining cells is pierced by strands of protoplasm. The whole structure, consisting of the two pits and the wall between, is known as a *genetic pit*. Other pits, connecting cells not belonging to the same branch, are, however formed at a later stage.

Many of the lower forms of Brown Seaweeds have a thallus consisting of simple or branched cell threads, as in the green and red forms. The lateral union of the branches to form a solid thallus is not, however, so common, nor is it carried to so high a pitch of elaboration as in the Rhodophyceæ. In a few of the lower forms (Sphacelariaceæ), and in the higher forms which possess a solid thallus often of very large size, the plant-body is no longer formed entirely of branched cell threads, but consists of what is called a true parenchymatous tissue, a solid mass of cells, that is to say, formed by cell division in all directions of space. In the Laminariaceæ this tissue is formed by cell division at what is called an *intercalary growing point*, i.e., a *meristematic* (cell-dividing) region occupying the whole of a certain zone of the thallus, and cutting off new cells to add to the permanent tissue on both sides. In the Fucaceæ, on the other hand, there is a single prismatic *apical cell* situated at the bottom of a groove at the growing apex of the thallus, which cuts off cells from its sides to add to the peripheral, and from its base to add to the central permanent cells. The whole of the tissue of the plant is formed by the division of this apical cell. In whatever way the tissues are originally formed, however, the main features of their differentiation are the same. According to a law which applies also to the green and red forms, the superficial cells are packed with chromatophores and form the assimilating tissue. In these brown types with bodies of considerable thickness (Laminariaceæ and Fucaceæ) there is, however, a further differentiation of the internal tissues. The cells immediately subjacent to the superficial assimilating layer form a colourless, or nearly colourless, parenchymatous *cortex*, which acts as a food storage tissue, and surrounds a central *medulla* of elongated conducting cells. The latter are often swollen at the ends, so

that the cross-wall separating two successive cells has a larger surface than if the cells were of uniform width along their entire length. Cells of this type are often called *trumpet-hyphæ*, and in some genera of Laminariaceæ those at the periphery of the medulla simulate the *sieve-tubes* of the higher plants in a striking degree, even developing the peculiar substance *callose* on or in the perforated cross-walls or sieve-plates. A specialized conducting tissue of this kind, used mainly for transmitting organic nitrogenous substances, is always developed in plants where the region of assimilative activity is local in the plant-body. This is the case in the Fucaceæ, and in a very marked degree in the Laminariaceæ in question, where the assimilative *frond* is borne at the end of a long supporting and conducting *stipe*. The tissue developed to meet the demands for conduction in such cases always shows some of the characters described. It is known as *leptom*, each constituent cell being a *leptoid*. In addition to the cell types described, it is a very common occurrence in these bulky forms for rhizoid-like branches of the cells to grow out mostly from the cells, at the periphery of the medulla, and grow down between the cells, strengthening the whole tissue, as in the Rhodophyceæ. This process may result in a considerable thickening of the thallus. In many Laminariaceæ the thallus also grows regularly in thickness by division of its surface layer, which thus forms a *secondary meristem*.

The simpler Fungi, like the simpler Green Algæ, consist of single cells or simple or branched cell threads, but among the

Tissue-differentiation in Fungi.

higher kinds a massive body is often formed, particularly in connexion with the formation of spores, and this may exhibit considerable tissue-differentiation. A characteristic feature of the fungal vegetative plant-body (*mycelium*) is its formation from independent cœnocytic tubes or cell threads. These branch, and may be packed or interwoven to form a very solid structure; but each grows in length independently of the others and retains its own individuality, though its growth in those types with a definite external form is of course correlated with that of its neighbours, and is subject to the laws governing the general form of the body. Such an independent cœnocytic branch or cell thread is called a *hypha*. Similar modes of growth occur among the Siphonous green and also among the red seaweeds. A solid fungal body may usually be seen to consist of separate hyphæ, but in some cases these are so bent and closely interwoven that an appearance like that of ordinary parenchymatous tissue is obtained in section, the structure being called *pseudoparenchyma*. By the formation of numerous cross-walls the resemblance to parenchyma is increased. The *surface-layer* of the body in the massive Fungi differs in character according to its function, which is not constant throughout the class, as in the Algæ, because of the very various conditions of life to which different Fungi are exposed. In many forms its hyphæ are particularly thick-walled, and may strikingly resemble the epidermis of a vascular plant. This is especially the case in the lichens (symbiotic organisms composed of a fungal mycelium in association with algal cells), which are usually exposed to very severe fluctuations in external conditions. The formation of a massive body naturally involves the localization of the absorptive region, and the function of absorption (which in the simpler forms is carried out by the whole of the vegetative part of the mycelium penetrating a solid or immersed in a liquid substratum) is subserved by the outgrowth of the hyphæ of the surface-layer of that region into *rhizoids*, which, like those of the Algæ, living on soil, resemble the root-hairs of the higher plants. The *internal tissue* of the body of the solid higher Fungi, particularly the elongated stalks (*stipes*) of the fructifications of the Agarics, consists of hyphæ running in a longitudinal direction, which no doubt serve for the conduction of plastic food substances, just as do the "trumpet-hyphæ," similar in appearance, though not in origin, of the higher brown seaweeds. (In one genus (*Lactarius*) "milk-tubes," recalling the laticiferous tubes of many vascular plants, are found.) These elongated hyphæ are frequently thick-walled, and in some cases form a central strand, which serves to resist longitudinal pulling strains. This is particularly marked in certain lichens of shrubby habit. The internal tissues, either consisting of obvious hyphæ or of pseudoparenchyma, may also serve as a storehouse of plastic food substances.

Looking back over the progress of form and tissue-differentiation in the Thallophyta, we find that, starting from the simplest unicellular forms with no external differentiation of the body, we can trace an increase in complexity of organization everywhere determined by the principles of the division of physiological labour and of the adaptation of the organism to the needs of its environment. In the first place there is a differentiation of fixing organs, which in forms living on a soft nutrient substratum

penetrate it and become absorbing organs. Secondly, in the Algæ, which build up their own food from inorganic materials, we have a differentiation of supporting axes from assimilating appendages, and as the body increases in size and becomes a solid mass of cells or interwoven threads, a corresponding differentiation of a superficial assimilative system from the deep-lying parts. In both Algæ and Fungi the latter are primarily supporting and food-conducting, and in some bulky Brown Seaweeds where assimilation is strongly localized some of the deep cells are highly specialized for the latter function. In the higher forms a storage and a mechanically-strengthening system may also be developed, and in some aerial Fungi an *external protective tissue*. The "hyphal" mode of growth, *i.e.*, the formation of the thallus, whatever its external form, by branched, continuous or septate, cœnocytic tubes (Siphonous and Fungi), or by simple or branched cell threads, in both cases growing mainly or entirely at the apex of each branch, is almost universal in the group, the exceptions being met with almost entirely among the higher brown seaweeds, in which is found parenchyma produced by the segmentation of an apical cell of the whole shoot, or by cell division in some other type of meristem.

Bryophyta.

The Bryophyta, the first group of mainly terrestrial plants, exhibit considerably more advanced tissue differentiation, in response to the greater complexity in the conditions of life on land. But the lowest Hepaticæ have an extremely simple vegetative structure, little more advanced than that found in some of the higher Green Algæ and very much simpler than in the large red and brown seaweeds. The thallus, however, always consists of true parenchyma, and is entirely formed by the cutting off of segments from an apical cell.

A sufficient description of the thallus of the Liverworts, *e.g.*, *Fegatella*, will be found in the article MUSCINEÆ (*Ency. Brit.* vol. xvii.). We may note the universal occurrence on the lower surface of the thallus of fixing and absorbing rhizoids in accordance with the terrestrial life on soil (cf. *Edocladium* among the Green Algæ). The Marchantiaceæ (see article MUSCINEÆ) show considerable tissue-differentiation, possessing a distinct assimilative system of cells, consisting of branched cell threads packed with chloroplasts and arising from the basal cells of large cavities in the upper part of the thallus. These cavities are completely roofed by a layer of cells; in the centre of the roof is a pore surrounded by a ring of special cells. The whole arrangement has a strong resemblance to the lacunæ, mesophyll and stomata, which form the assimilative and transpiring (water-evaporating) apparatus in the leaves of flowering plants. The frondose (thalloid) Jungermanniaceæ show no such differentiation of an assimilating tissue, though the upper cells of the thallus usually have more chlorophyll than the rest. In three genera—*Pallavicinia*, *Symphogyna*, and *Hymenophyton*—there are one or more strands or bundles consisting of long thick-walled fibre-like cells, pointed at the ends and running longitudinally through the thick midrib. The walls of these cells are strongly lignified (*i.e.*, consist of woody substance) and are irregularly but thickly studded with simple pits (see CYTOLOGY), which are usually arranged in spirals running round the cells, and are often elongated in the direction of the spiral (Fig. 1 I). These cells are not living in the adult state, though they sometimes contain the disorganized remains of protoplasm. There is little doubt that their function is to conduct water through the thallus, the assimilating parts of which are in these forms often raised above the soil and comparatively remote from the rhizoid-bearing (water-absorbing) region. Such differentiated water-conducting cells we call *hydroids*, the tissue they form *hydrom*. The sporogonium of the liverworts is in the simpler forms simply a spore-capsule with arrangements for the development, protection, and distribution of the spores. As such it falls outside the scheme of this article, but in one small and peculiar group of these plants, the *Anthocerotæ*, a distinct assimilating and transpiring system is found in the wall of the very long cylindrical capsule, clearly enabling the sporogonium to be largely independent of the supply of elaborated organic food from the thallus of the mother plant (the gametophyte). A richly chlorophyllous tissue with numerous intercellular spaces communicates with the exterior by stomata, strikingly similar to those of the vascular plants (see below). If

the axis of such a sporogonium were prolonged downwards into the soil to form a fixing and absorptive root, the whole structure would become a physiologically independent plant, exhibiting in many things by no means all respects the leading features of the *sporophyte* or ordinary vegetative and spore-bearing individual in Pteridophytes and Phanerogams. These facts have led to the theory, plausible in many respects, of the origin of this sporophyte by descent from an Anthoceros-like sporogonium (see ΠΡΕΡΙΔΟΡΗΥΤΑ). The facts, however, give us no warrant for asserting homology (*i.e.* identity by descent) between the tissues of an Anthocerocean sporogonium and those of the sporophyte in the higher plants.

In the Mosses the plant-body (gametophyte) is always separable into a radially organized, supporting and conducting axis (stem) and thin, flat, assimilating, and transpiring appendages (leaves). [For the histology of the comparatively simple but in many respects aberrant Bog-mosses (Sphagnaceæ), see MUSCINEÆ, *Ency. Brit.* vol. xvii.] The stems of the other mosses resemble one another in their main histological features. In a few cases there is a special surface or epidermal layer, but usually all the outer layers of the stem are composed of brown, thick-walled, lignified, prosenchymatous, fibre-like cells forming a peripheral *stereom* (mechanical or supporting tissue) which forms the *outer cortex*. This passes gradually into the thinner-walled parenchyma of the *inner cortex*. The whole of the cortex, stereom and parenchyma alike, is commonly living and its cells often contain starch. The centre of the stem in the forms living on soil is occupied by a strand of narrow elongated hydroids, which differ from those of the liverworts in being thin-walled, unligified, and very seldom pitted. The hydrom strand has in most cases no connexion with the leaves, but runs straight up the stem and spreads out below the sexual organs or the foot of the sporogonium. It has been shown that it conducts water with considerable rapidity. In the stalk of the sporogonium there is a similar strand, which is of course not in direct connexion with, but continues the conduction of water from, the strand of the gametophytic axis. In the aquatic, semiaquatic, and xerophilous types, where the whole surface of the plant absorbs water, perpetually in the first two cases and during rain in the last, the hydrom strand is either much reduced or altogether absent. In accordance with the general principle already indicated, it is only where absorption is localized (*i.e.*, where the plant lives on soil from which it absorbs its main supply of water by means of its basal rhizoids) that a water-conducting (hydrom) strand is developed. The leaves of most mosses are flat plates, each consisting of a single layer of square or oblong assimilating (chlorophyllous) cells. In many cases the cells bordering the leaf are produced into teeth, and very frequently they are thick-walled so as to form a supporting rim. The centre of the leaf is often occupied by a *midrib* consisting of several layers of cells. These are elongated in the direction of the length of the leaf, are always poor in chlorophyll, and form a channel for conducting the products of assimilation away from the leaf into the stem. This is the first indication of a conducting foliar strand or *leaf bundle*, and forms an approach to leptom, though it is not so specialized as the leptom of the higher Phæophyceæ. Associated with the conducting parenchyma are frequently found hydroids identical in character with those of the central strand of the stem, and no doubt serving to conduct water to or from the leaf according as the latter is acting as a transpiring or water-absorbing organ. In a few cases the hydrom strand is continued into the cortex of the stem as a *leaf-trace* bundle (the anatomically demonstrable *trace* of the leaf in the stem). This in several cases runs vertically downwards for some distance in the outer cortex, and ends blindly—the lower end or the whole of the trace being band-shaped or star-shaped so as to present a large surface for the absorption of water from the adjacent cortical cells. In other cases the trace passes inwards and joins the central hydrom strand, so that a connected water-conducting system between stem and leaf is established.

In the highest family of mosses, Polytrichaceæ, the differentiation of conducting tissue reaches a decidedly higher level. In addition to the water-conducting tissue or *hydrom* there is a well-developed tissue inferred to be a conducting channel for nitrogenous substances or *leptom*, not indeed so highly differentiated as in the most advanced Laminariaceæ, but showing some of the characters of sieve-tubes with great distinctness. Each leptoid is an elongated living cell with nucleus and a thin layer of protoplasm lining the wall. The whole cavity of the cell is sometimes stuffed with proteid contents. The end of the cell is slightly swollen, fitting on to the similar swollen end of the next leptoid of the row exactly after the fashion of a trumpet-hypha. The end-wall is usually very thin, and the protoplasm on artificial contraction commonly sticks to it just as in a sieve-tube, though no perforation of the wall has been found. Associated with the leptoids are similar cells without swollen ends and with thicker cross walls. Besides the hydrom and leptom, and situated between them, there

is a tissue which probably serves to conduct soluble carbohydrates, and whose cells are ordinarily full of starch. This may be called *amylom*. The stem in this family falls into two divisions, an underground portion bearing rhizoids and scales, the *rhizome*, and a *leafy aerial stem* forming its direct upward continuation. The leaf consists of a central midrib, several cells thick, and two wings, one cell thick. The midrib bears above a series of closely set, vertical, longitudinally-running plates of green assimilative cells over which the wings close in dry air so as to protect the assimilative and transpiring plates from excessive evaporation of water. The midrib has a strong band of stereom above and below. In its centre is a band-shaped bundle consisting of rows of leptom, hydrom, and amylo-m cells. This bundle is continued down into the cortex of the stem as a leaf trace, and passing very slowly through the sclerenchymatous external cortex and the parenchymatous, starchy internal cortex to join the central cylinder. The latter has a central strand consisting of files of large hydroids, separated from one another by very thin walls, each file being separated from its neighbour by stout, dark-brown walls. This is probably homologous with the hydroid cylinder in the stems of other mosses. It is surrounded by (1) a thin-walled, smaller-celled hydrom mantle; (2) a suberized amylo-m sheath; (3) a leptom mantle, interrupted here and there by starch cells. These three concentric tissue mantles are evidently formed by the conjoined bases of the leaf traces, each of which is composed of the same three tissues. As the aerial stem is traced down into the underground rhizome portion, these three mantles die out almost entirely—the central hydrom strand forming the bulk of the cylinder and its elements becoming mixed with thick-walled stereids; at the same time this central hydrom-stereom strand becomes three-lobed, with deep furrows between the lobes in which the few remaining leptoids run, separated from the central mass by a few starchy cells, the remains of the amylo-m sheath. At the periphery of the lobes are some comparatively thin-walled living cells mixed with a few thin-walled hydroids, the remains of the thin-walled hydrom mantle of the aerial stem. Outside this are three arcs of large cells showing characters typical of the endodermis in a vascular plant; these are interrupted by strands of narrow, elongated, thick-walled cells which send branches into the little brown scales borne by the rhizome. The surface layer of the rhizome bears rhizoids, and its whole structure strikingly resembles that of the typical root of a vascular plant. In *Atrichum undulatum* the central hydrom cylinder of the aerial stem is a loose tissue, its interstices being filled up with thin-walled, starchy parenchyma. In *Dawsonia superba*, the finest of all known mosses, the hydroids of the central cylinder of the aerial stem are mixed with thick-walled stereids forming a hydrom-stereom strand somewhat like that of the rhizome in other Polytrichaceæ.

The central hydrom strand in the seta of the sporogonium of most mosses has already been alluded to. Besides this there is usually a living conducting tissue, sometimes differentiated as leptom, forming a mantle round the hydrom, and bounded externally by a more or less well-differentiated endodermis, abutting on an irregularly cylindrical lacuna; the latter separates the central conducting cylinder from the cortex of the seta, which, like the cortex of the gametophyte stem, is usually differentiated into an outer thick-walled stereom and an inner starchy parenchyma. Frequently, also, a considerable differentiation of vegetative tissue occurs in the wall of the spore-capsule itself, and in some of the higher forms a special assimilating and transpiring organ situated just below the capsule at the top of the seta, with a richly lacunar chlorophyllous parenchyma and stomata like those of the wall of the capsule in the Anthocerocean liverworts. Thus the histological differentiation of the sporogonium of the higher mosses is one of considerable complexity; but there is here even less reason to suppose that these tissues have any homology (phylogenetic community of origin) with the similar ones met with in the higher plants.

The facts of histological structure in the Bryophytic series are all such as we should expect to be developed in response to the exigencies of increasing adaptation to terrestrial life on soil, and of increasing size of the plant-body. In the liverworts we find fixation of the thallus by water-absorbing rhizoids; in certain forms with a localized region of water-absorption the development of a primitive hydrom or water-conducting system; and in others with rather a massive type of thallus the differentiation of a special assimilative and transpiring system. In the more highly developed series, the mosses, this last division of labour takes the form of the differentiation of special assimilative organs, the leaves, commonly with a midrib containing elongated cells for the ready removal of the products of assimilation; and in the typical forms with

a localized absorptive region, a well-developed hydrom in the axis of the plant, as well as similar hydroid strands in the leaf-midribs, are constantly met with. In higher forms the conducting strands of the leaves are continued downwards into the stem, and eventually come into connexion with the central hydroid cylinder, forming a complete cylindrical investment apparently distinct from the latter, and exhibiting a differentiation into hydrom, leptom, and amylo which almost completely parallels that found among the true vascular plants. Similar differentiation, differing in some details, takes place independently in the other generation, the sporogonium. The stereom of the moss is found mainly in the outer cortex and in the midrib of the leaf.

Vascular Plants.

The body of the sporophyte in the great majority of the vascular plants (Pteridophytes and Phanerogams) shows a considerable increase in complexity over that found in the Bryophytes. The principal new feature in the external conformation of the body is the acquirement of "true" roots, the nearest approach to which in the lower forms we saw in the "rhizome" of Polytrichaceæ. The primary root is a downward prolongation of the primary axis of the plant. From this, as well as from various parts of the shoot system, other roots may originate. The root differs from the shoot in the characters of its surface tissues, in the arrangement of its vascular system, and in the mode of growth at the apex, all features which are in direct relation to its normally subterranean life and its fixative and absorptive functions. Within the limits of the sporophyte generation the Pteridophytes and phanerogams also differ from the Bryophytes in possessing special assimilative and transpiring organs, the leaves, though these organs are also developed in the gametophyte of many liverworts and of all the mosses. The leaves, again, have special histological features adapted to the performance of their special functions.

Alike in root, stem, and leaf, we can trace a three-fold division of tissue-systems, a division of which there are indications among the lower plants, and which is the expression of the fundamental conditions of the evolution of a bulky differentiated plant-body. From the primitive uniform mass of undifferentiated assimilating cells, there is, on the one hand, a specialization of a surface layer regulating the immediate relations of the plant with its surroundings. In the typically submerged algæ and in submerged plants of every affinity this is the absorptive and the main assimilative layer, and may also by the production of mucilage be of use in the protection of the body in various ways. In the terrestrial plants it differs in the subterranean and subaerial parts, being in the former pre-eminently absorptive, and in the latter protective—provision at the same time being made for the gaseous interchange of oxygen and carbon dioxide necessary for respiration and feeding. This surface layer in the typically subaerial "shoot" of the sporophyte in Pteridophytes and Phanerogams is known as the *epidermis*, though the name is restricted by some writers, on account of developmental differences, to the surface layer of the shoot of Angiosperms, and by others extended to the surface layer of the whole plant in both these groups. On the other hand, we have an internal differentiation of conducting tissue, the main features of which have already been fully described. The remaining tissue of the plant-body, a tissue that we must regard phylogenetically as the remnant of the undifferentiated tissue of the primitive thallus, but which often undergoes further differentiation of its own, the better to fulfil its characteristically vital functions for the whole plant, is known, from its peripheral position in relation

to the primitively central conducting tissue, as the *cortex*. The remaining important function for which provision has to be made in any plant-body of considerable size, especially when raised into the air, is that of *support*. Special tissues may be developed for this purpose in the cortex, or in immediate connexion with the conducting system, according to the varying needs of the particular type of plant-body.

In relation to its characteristic function of protection, the epidermis, which, as above defined, consists of a single layer of cells, has typically thickened and cuticularized outer walls. These serve not only to protect the plant *Epidermis* against slight mechanical injury from without, but also and especially to prevent the evaporation of water from within, and to protect the internal tissues from the soaking in of rain, &c. At intervals it is interrupted by pores leading from the air outside to the intercellular space system below. These *stomata* are each surrounded by a pair of peculiarly modified epidermal cells called *guard-cells*, which open and close the pore according to the need for transpiration. The structure of the stomata of the sporophyte of vascular plants is fundamentally the same as that of the stomata on the sporogonium of the true mosses and of the liverwort *Anthoceros*, a striking fact that lends countenance to the theory which would derive the Pteridophytic sporophyte from the sporogonium of an *Anthoceros*-like ancestor. The stomata serve for all gaseous interchange between the plant and the surrounding air. The guard-cells contain chlorophyll, which is absent from typical epidermal cells, the latter acting as a tissue for water storage. Sometimes the epidermis is considerably more developed by tangential division of its cells, forming a many-layered water-tissue. The extremely various modifications of the epidermis, especially in connexion with the occurrence of *hairs* of the most various kinds, and the numberless differences in the distribution of the stomata, and their relation to the general surface of the epidermis, are concisely treated as to the leading facts in BOTANY (*Ency. Brit.* vol. iv. pp. 89-91), and in HISTOLOGY (vol. xii. p. 17). Mention may be made here of a class of epidermal organ, the *hydathode*, the wide distribution and variety of which have been revealed by recent research. These are special organs usually situated on foliage *Hydathodes*. leaves for the excretion of water in liquid form when transpiration is diminished so that the pressure in the water-channels of the plant has come to exceed a certain limit. They are widely distributed, but are particularly abundant in the tropics. In one type they may take the form of specially-modified single epidermal cells or multicellular hairs without any direct connexion with the vascular system. The cells concerned, like all secreting organs, have abundant protoplasm with larger nuclei, and sometimes, in addition, part of the cell-wall is modified as a filter. In a second type they are situated at the ends of tracheal strands and consist of groups of richly protoplasmic cells belonging to the epidermis (leaves of many ferns), or to the subjacent tissue (the commonest type in flowering plants); in this last case the cells in question are known as *epithema*. The epithema is penetrated by a network of fine intercellular spaces, which are normally filled with water and debouch on one or more intercellular cavities below the epidermis. Above each cavity is situated a so-called *water-stoma*, no doubt derived phylogenetically from an ordinary stoma, and enclosed by guard-cells which have nearly or entirely lost the power of movement. The pores of the water-stomata are the outlets of the hydathode. The epithema is frequently surrounded by a sheath of cuticularized cells; in other cases the epithema may be absent altogether, the tracheal strand debouching directly on the lacunæ of the mesophyll. This last type of hydathode is usually situated on the edge of the leaf. Some hydathodes are active *glands*, secreting the water they expel from the leaf. Many other types of glands also exist, either in connexion with the epidermis or not, such as nectaries, digestive glands, oil, resin and mucilage glands, &c.

The surface layer of the root, sometimes included under the term epidermis, is fundamentally different from the epidermis of the stem. In correspondence with its water-absorbing function it is not cuticularized, but remains usually thin-walled; the absorbing surface is increased by its cells being often produced into delicate tubes which curl round and adhere firmly to particles of soil, thus at once fixing the root firmly in the soil, and enabling the hair to absorb readily the thin films of water ordinarily surrounding the particles. The *root-hair* ends blindly and is simply an outgrowth from a surface cell, having no cross walls. It corresponds in function with the rhizoid of a bryophyte. At the apex of a root, covering and protecting the delicate tissue of the growing point, is a special

root-cap consisting of a number of layers of tissue whose cells break down into mucilage towards the outer surface, thus facilitating the passage of the apex as it is pushed between the particles of soil.

The cortex, as has been said, is in its origin the remains of the primitive assimilating tissue of the plant, after differentiation of the surface layer and the conducting system. It consists primitively and mainly of typical living parenchyma; but its differentiation may be extremely varied, since in the complex body of the higher plants its functions are very various. In all green plants, where there is a special protective epidermis, the cortex of the shoot has to perform the primitive fundamental function of carbon assimilation. In the leafy shoot this is mainly localized in the cortical tissue of the leaves, known as *mesophyll*, which is essentially a parenchymatous tissue containing chloroplasts, and penetrated by a lacunar system so that the surfaces of the assimilating cells are brought into contact with air to as large an extent as possible in order to facilitate gaseous interchange between the assimilating cells and the atmosphere. At the same time the cells of the mesophyll are transpiring cells—i.e., the evaporation of water from the leaf goes on from them into the intercellular spaces. The only pathways for the gases which thus pass between the cells of the mesophyll and the outside air are the stomata. A typical land plant has always to protect itself against over-transpiration, and for this reason the stomata are placed mainly or exclusively on the lower side of the leaf, where the water-vapour that escapes from them, being lighter than air, cannot rise away from the surface of the leaf, but remains in contact with it and thus tends to check further transpiration. The stomata are in direct communication with the richest lacunar system, which is found in the loosely arranged mesophyll (*spongy tissue*) on that side. This is the main transpiring tissue, and is protected from direct illumination and consequent too great evaporation. The main assimilating tissue, on the other hand, is under the upper epidermis, where it is well illuminated, and consists of oblong cells densely packed with chloroplasts and with their long axes perpendicular to the surface (*palisade tissue*). The intercellular spaces are here fewer and narrower. The whole lacunar system thus forms a kind of funnel, with its narrow end in the palisade and its wide end under the stomata, so that the double necessity for the limitation of transpiration and the illumination of the palisade cells lessens the amount of carbon dioxide which can reach the latter. Leaves whose blades are placed vertically possess palisade tissue and stomata on both sides (*isobilateral leaves*), since there is no difference in the illumination, while those which are cylindrical or of similar shape (*centric leaves*) have it all round. The leaves of shade plants have little or no differentiation of palisade. In fleshy leaves which have little or no chlorophyll, the central mesophyll is abundant and acts as water-storage tissue. The cortex of a young stem is usually green, and plays a more or less important part in the assimilative function. It also always possesses a well-developed lacunar system communicating with the external air through stomata (in the young stem) or *lenticels* (see below). This lacunar system not only enables the cells of the cortex itself to respire, but also forms channels through which air can pass to the deeper-lying tissues. The cortex of the older stem and of the root frequently acts as a reserve store-house for food, which generally takes the form of starch, and it also assists largely in providing the stereom of the plant. In the leaf-blade this often appears as a layer of thickened subepidermal cells, the *hypoderm*, often also as subepidermal bundles of sclerenchymatous fibres or of similar bundles extending right across the leaf from one epidermis to the other, and thus acting as struts. Isolated cells (*idioblasts*), thickened in various ways, are not uncommonly found supporting the tissues of the leaf. In the larger veins of the leaf, especially the midrib, in the petiole and in the young stem, an extremely frequent type of mechanical tissue is *collenchyma*. This consists of elongated cells with cellulose walls, which are locally thickened along the original corners of the cells, reducing the lumen to a cylinder, so that a number of vertical pillars of cellulose connected by comparatively thin walls form the framework of the tissue. This tissue remains living and is usually formed quite early just below the epidermis, where it provides the first peripheral support for a still growing stem or petiole. Sclerenchyma may be formed later in various positions in the cortex, according to local needs. Scattered single stereids or bundles of fibres are not uncommon in the cortex of the root.

Cortex.

The innermost layer of the cortex, abutting on the central cylinder of the stem or on the bundles of the leaves, is called the *phlocooterma*, and is often differentiated. In the leaf-blade it takes the form of special parenchymatous sheaths to the bundles. The cells of these sheaths are often distinguished from the rest of the mesophyll by containing little or no chlorophyll. Occasionally, however, they are particularly rich in chloroplasts. These bundle sheaths are important in the conduction of carbohydrates away from the

Phlocooterma.

assimilating cells to other parts of the plant. Rarely in the leaf, fairly frequently in the stem (particularly in Pteridophytes), and universally in the root, the phlocooterma is developed as an *endo-dermis* (see below). In other cases, it does not differ histologically from the parenchyma of the rest of the cortex, though it is often distinguished by containing particularly abundant starch, in which case it is known as a *starch sheath*.

One of the most striking characters common to the two highest groups of plants, the Pteridophytes and Phanerogams, is the possession of a double (hydrom-leptom) conducting system, such as we saw among the highest mosses, but with sharply characterized and peculiar features, almost certainly indicating common descent throughout both these groups. It is confined to the sporophyte, which forms the leafy-plant in these groups and is known as the *vascular system*. Associated with it are other tissues, consisting primitively of parenchyma, mainly starchy, and in the Phanerogams particularly, of special stereom. The whole tissue system is known as the *Stelar system*. It has no direct phylogenetic connexion with that of the mosses. The origin of the Pteridophyta (*q.v.*) is very obscure, but it may be regarded as certain that it is not to be sought among the mosses, which are an extremely specialized and peculiarly differentiated group. Furthermore, both the hydrom and leptom of Pteridophytes have marked peculiarities to which no parallel is to be found among the Bryophytes. Hence we must conclude that the conducting system of the Pteridophytes has had an entirely separate evolution. All the surviving forms, however, have a completely established double system with the specific characters alluded to, and since there is every reason to believe that the conditions of evolution of the primitive Pteridophyte must have been essentially similar to those of the Bryophytes, the various stages in the evolution of the conducting system of the latter are very useful to compare with the arrangements met with in the former. The hydroid of a Pteridophyte or of a Phanerogam is characteristically a dead, usually elongated, cell containing air and water, and either thin-walled with lignified spiral or annular thickenings, or with thick lignified walls, incompletely perforated by pits (usually bordered pits) of various shapes. When a number of such cells, called *tracheids*, placed end to end, have open communication with one another, the resulting cell-fusion is called a *vessel*. Vessels are very rare among Pteridophytes, though common among Phanerogams. The tracheids or vessels, indifferently called *tracheal elements*, together with the immediately associated cells (usually amyloem in Pteridophytes) constitute the *xylem* of the plant. This is a morphological term given to the particular type of hydrom found in both Pteridophytes and Phanerogams, together with the parenchyma or stereom, or both, included within the boundaries of the hydrom tissue strand. The leptoid of a Pteridophyte is also an elongated cell, with a thin lining of protoplasm, but destitute of a nucleus, and always in communication with the next cell of the leptom strand by relatively large perforations (in Pteridophytes often not easily demonstrable), through which pass strings of protoplasm. These are often converted into a peculiar substance called *callose*, which is also frequently formed over the surface of the perforated, often extremely oblique, end-walls. The structure formed by a number of such cells placed end to end is called a *steve-tube* (obviously comparable with a xylem-vessel), and the end-wall or area of end-wall occupied by a group of perforations, a *steve-plate* (see CYTOLOGY). The sieve-tubes, with their accompanying parenchyma or stereom, constitute the tissue called *phloem*. This is likewise the term for a morphologically defined tissue system, i.e. the leptom found in Pteridophytes and Phanerogams with its associated cells, and is entirely parallel with the xylem. The sieve-tubes differ, however, from the tracheids in being immediately associated, apparently constantly, not with starchy parenchyma, but with parenchymatous cells containing particularly abundant proteid contents which seem to have a function intimately connected with the conducting function of the sieve-tubes, and which we may call *proteid-cells*.

The xylem and phloem are nearly always found in close association in strands of various shapes in all the three main organs of the sporophyte—root, stem, and leaf—and form a connected tissue-system running through the whole body. In the primary axis of the plant among Pteridophytes and many Phanerogams, at any rate in its first formed part, the xylem and phloem are associated in the form of a cylinder, with xylem occupying the centre, and the phloem (in the upward growing part or primary stem) forming a mantle to the periphery (Fig. 3). In the downward growing part of the axis (primary root), however, the peripheral mantle of phloem is interrupted, the xylem coming to the surface of the cylinder along (usually) two or (sometimes) more vertical lines. Such an arrangement of vascular tissue is called *radial*, and is characteristic of all roots (Figs. 2 and 9). The cylinder is surrounded by a mantle of one or more layers of

Vascular system.

Tissue elements.

Arrangement in strands: the central cylinder or monostele.

parenchymatous cells, the *pericycle*, and the xylem is separated from the phloem in the stem by a similar layer, the *mesocycle* (corresponding with the hydrom sheath in mosses). The *pericycle* and *mesocycle* together form the *conjunctive tissue* of the stele. In the root the *mesocycle*, like the phloem, is interrupted, and runs into the *pericycle* where the xylem touches the latter (Fig. 2). The whole cylinder is enclosed by the peculiarly differentiated innermost cell-layer of the cortex, known as the *endodermis*. This layer has its cells closely united and sealed to one another, so to speak, by the conversion of the radial and transverse walls (which separate each cell from the other cells of the layer), or a band running in the centre of these, into corky substance, so that the endodermal cells cannot be split apart to admit of the formation of intercellular spaces, and an air-tight sheath is formed round the cylinder. Such a vascular cylinder is called a *protostele*, and the axis containing it is said to be *protomonostelic*. In the stele of the root the strands of tracheids along the lines where the xylem touches the *pericycle* are spiral or annular, and are the xylem elements first formed when the cylinder is developing. Each strand of spiral or annular first-formed tracheids is called a *protoxylem* strand, as distinct from the *metaxylem* or rest of the xylem, which consists of thick-walled tracheids, the pits of which are usually scalariform. The stele is called *monarch*, *diarch*, . . . *polyarch* according as it contains one, two, . . . or many *protoxylems*. When the *protoxylem* strands are situated at the periphery of the stele, abutting on the *pericycle*, as in all roots, and many of the more primitive Pteridophyte stems, the stele is said to be *exarch*. When there is a single *protoxylem* strand in the centre of the stele, or when, as is more commonly the case, there are several *protoxylem* strands situated at the internal limit of the xylem, the centre of the stem being occupied by parenchyma, the stele is *endarch*. This is the case in the stems of most Phanerogams and a few Pteridophytes. When the *protoxylems* have an intermediate position the stele is *mesarch* (many Pteridophytes and some of the more primitive Phanerogams). In many cases external *protophloem*, usually consisting of narrow sieve-tubes often with swollen walls, can be distinguished from *metaphloem*. As the primitive stele of an exarch Pteridophyte is traced upwards from the primary root into the stem, the phloem and *mesocycle* become continuous round the xylem. At the same time the stele becomes more bulky, all its elements increasing in number. Very frequently the number of *protoxylem* strands increases by branching of the original ones that have come up from the root. Soon a bundle goes off to the first leaf. This consists of a *protoxylem* with a few *metaxylem* elements, a segment of *mesocycle*, *phloem*, *pericycle*, and usually an arc of *endodermis*, which closes round the bundle as it detaches itself from the stele. Thus such a leaf-bundle contains parts of all the tissues of the stele, and is hence called a *meristele*. It is primitively bilaterally symmetrical like the leaf it supplies, though it may acquire a radial symmetry of its own, while the stele of the stem is primitively radially symmetrical like the stem itself. As the stele is traced farther upwards it becomes bulkier, as do the successive leaf-bundles which leave it. In many Pteridophytes the solid *protostele* is maintained throughout the axis. In others a central parenchyma or *primitive pith*—a new region of the primitive stelar conjunctive—appears in the centre of the xylem. In many ferns *internal phloem* appears associated with this primitive pith; and at a higher level, after the stele has increased greatly in diameter, a large-celled *true pith* or *medulla*, resembling the cortex in its characters and usually quite distinct from conjunctive, appears in the centre. This is often separated from the conjunctive by an *internal endodermis*. Where *internal phloem* is present this is separated from the *internal endodermis* by an *endocycle* or “internal *pericycle*,” as it is sometimes called, and from the xylem by an *internal mesocycle*—these two layers, together with the outer *mesocycle* and *pericycle*, constituting the conjunctive tissue of the now hollow cylindrical stele. (The conjunctive frequently forms a connected whole with bands of starchy *xylem-parenchyma*, which, when the xylem is bulky, usually appear among the tracheids, the phloem also often being penetrated by similar bands of *phloem-parenchyma*.) To this type of stele, whether with or without *internal phloem*, is given the name *siphonostele* to distinguish it from the solid *protostele* characteristic of the root, of the first-formed portion of the stem, and in the more primitive Pteridophytes of the whole of the axis. The *siphonostele* is, as it is found among many of the lower ferns, broken by the departure of a leaf-bundle, the outer and inner *endodermis* joining so that the stele becomes horseshoe-shaped and the cortex continuous with the pith (Fig. 4). Such a break is known as a *leaf-gap*. A little above the departure of the leaf-bundle the stele again closes up, only to be again broken by the departure of the next *meristele*. Where the leaves are crowded and the phyllotaxy is high, a given *leaf-gap* is not closed before the next ones appear, and the *siphonostele* thus becomes split up into a number of segments, sometimes band-

shaped or semilunar, sometimes isodiametric in cross-section (Fig. 5). Each segment of the *siphonostele* frequently resembles a *protostele*, the segments of inner *endodermis*, *pericycle*, *phloem*, and *mesocycle* joining with the corresponding outer segments to form a concentric structure. For this reason a stem in which the vascular system has this type of structure is spoken of as *polystelic*, the term “*stele*” being transferred from the primary central cylinder of the axis and applied to the vascular strands just described. In this use the term loses, of course, its morphological value. Where the “*steles*” are few and band-shaped on cross-section, the structure is spoken of as “*gamostelic*”; where they are numerous, and run independently for considerable distances, it is “*dialystelic*.” The splitting up of the vascular tube or *siphonostele* into separate strands does not depend wholly upon the occurrence of *leaf-gaps*. In the extremely *dialystelic* forms the *leaf-gaps* are very broad and long, and are filled by a network of slender strands, some of which run out to the leaf, while others form cross connexions between these and with the strands separating the gaps, which, though stouter than the *leaf-gap steles*, are reduced to comparatively narrow bands. In some cases the strands separating the gaps are themselves split up, further increasing the *dialystely*. Finally, the original *dialystelic* cylinder may be supplemented by additional internal or external strands or both, joining by frequent connexions the primary ones. The *leaf-trace* consists of a single strand only in some of the *protostelic* and more primitive *siphonostelic* forms, in the latter (where it is simply a detached segment of the *siphonostele*) having the shape of a crescent or horse-shoe in cross-section with the convexity outwards, and in the petiole downwards. In the more complex forms, as already indicated, the trace is itself split up into a number of strands which leave the base and sides of the *leaf-gap* independently. In the petiole these may increase in number by branching and sometimes form a complicated system resembling that of the stem, but usually reducible to the primitive bilateral horse-shoe type. The *protostelic*, *siphonostelic*, and “*polystelic*” conditions are mainly found among the Pteridophytes. There is good reason to suppose that the *protostelic* condition is primitive in evolution. Essentially the same type was found in the primitive conducting system of the gametophyte of the mosses. No doubt the *siphonostele* came next, sometimes perhaps in relation to the necessity for the formation of a hard peripheral supporting cylinder, but often owing to factors not yet understood, and by the crowding of the *leaf-gaps* and other factors the “*polystelic*” state was reached. Thus in tracing the stelar system of a “*polystelic*” fern, for instance, upwards from the primary root, the various stages which have led to the evolution of this type are passed through. In a few Pteridophytes and the great majority of the Phanerogams, the *protostele* of the primary root dilates either immediately upon entering the stem, or at a higher level, acquires a true medulla, and the vascular cylinder breaks into a number of separate *collateral bundles* (*i.e.*, with xylem towards the centre and phloem towards the periphery of the stem) which pass out of the cylinder to supply the leaves after having given off branches (*continuation bundles*) which continue their course in the cylinder of the stem. The lowest *collateral bundles* of the typical Phanerogamic stem are frequently directly continuous with the (often separate) strands forming the stele of the primary root, so that no *siphonostelic* condition of the type always found near the base of the stem of a higher Pteridophyte is passed through. But the *collateral bundles* of the stem stele are usually united laterally by conjunctive tissue, so that a hollow cylinder of stelar tissue is maintained, and the pith is isolated from the cortex except at the *leaf-gaps*. This modified *siphonostele* is very characteristic of the Phanerogamic stem. In the great majority of cases there is a fairly wide *pericycle* outside the *phloem*, and this is partially or wholly converted into sclerenchyma, usually of the prosenchymatous (fibrous) type. In this way an efficient peripheral supporting cylinder is secured, and it is no doubt largely owing to the need for this mechanical support that the modified *siphonostele* is maintained in the Phanerogamic stem. As it is, the single *collateral bundle* often asserts its individuality while still within the stele, the conjunctive being obviously arranged round them as centres—the sclerized *pericycle*, for instance, taking the form of a number of bands, arc-shaped in cross-section, capping the phloems of the bundles, and the cortex and medulla frequently intruding between two adjacent ones (Fig. 6). In some cases, indeed, the modified *siphonostele* breaks up altogether, the cortex and medulla becoming continuous between the bundles, each of which is surrounded by its own investment of tissue corresponding with conjunctive, but now called *peridesm*, the isolated segment of the *mesocycle* being known as *mesodesm*. This is the condition of *astely*, entirely parallel with *polystely* except that the separate strands are usually all or mostly *leaf-traces*. The difference between the concentric and the *collateral* structure of the strands, depending mainly on the presence or absence of *internal phloem*, and the difference between the rounded “*stele*”

“*Poly-stely*.”

the departure of the next *meristele*. Where the leaves are crowded and the phyllotaxy is high, a given *leaf-gap* is not closed before the next ones appear, and the *siphonostele* thus becomes split up into a number of segments, sometimes band-

Astely.

of the polystelic Pteridophyte with its tendency to radial organization, and the unipolar wedge-shaped "bundle" of the Dicotyledon usually with its cap or sheath of peridesmic stereom, depending on the different characters of the siphonostele from which the two types have been respectively evolved, though

striking and characteristic enough, are of comparatively minor importance. The characteristic type of arrangement of vascular strands found in monocotyledonous stems depends on a similar extreme assertion of the individuality of the single leaf-trace bundle, combined with an often enormous increase in the number

FIGS. 2-9.—DIAGRAMS OF THE MAIN TYPES OF ARRANGEMENT OF THE STELAE IN PTERIDOPHYTES AND PHANEROGAMS (as seen in transverse section).

The xylem is cross-hatched, the phloem shaded diagonally, protoxylem and protophloem shaded darkly, parenchymatous conjunctive tissue left white, sclerenchyma dotted.

FIG. 2.—Diarch root-stele, with axial metaxylem plate joining the two protoxylems; the commonest type of primary root-stele.

FIG. 3.—Solid exarch protoctele (represented as pentarch); base of most Pteridophyte stems, and throughout stem of more primitive forms.

FIG. 4.—Typical siphonostele (represented as mesarch) with internal phloem, broken by departure of a meristelic leaf-trace on the right. Characteristic of base of stem in most ferns, and of whole axis in many.

FIG. 5.—Simple dialytelic type; mesarch siphonostele represented as broken by two opposite leaf-gaps (right and left), each containing three meristelic leaf-traces, simulating protocteles and usually known as steles. Characteristic of the stems of most of the higher ferns.

FIG. 6.—Modified siphonostele with collateral endarch bundles separated laterally by conjunctive tissue. The regions of the latter outside the phloems are sclerized, as is usually the case. Characteristic of the dicotyledonous stem.

FIG. 7.—Separate collateral endarch bundle of an astelic form surrounded by its periderm which may be partly or wholly sclerized. Xylem and phloem separated by mesoderm. Some dicotyledonous stems.

FIG. 8.—Meristelic arc of collateral bundles, united by conjunctive. Common in petioles of Dicotyledons.

FIG. 9.—Large polyarch root-siphonostele, showing radial arrangement of primary xylem and phloem in alternate strands, and also additional internal metaxylem, mostly in the form of large vessels. Found in many Monocotyledons. Most roots show some form intermediate between this and that represented in Fig. 2.

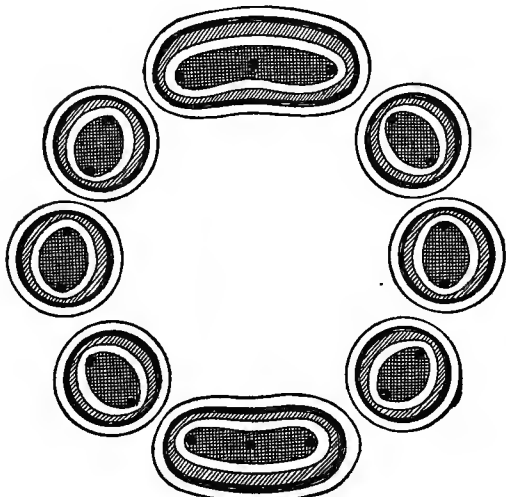

Fig. 5.

of bundles present at any given level. The result is a dilation of the stele till it occupies the whole or nearly the whole of the axis, the cortex being reduced to a narrow cylinder or disappearing altogether. The pericycle usually forms a sclerized band at or near the periphery of the stem, and the leaf-trace bundles are scattered in a definite though not superficially obvious order through a general parenchymatous ground tissue, each bundle being commonly capped or surrounded by its own sheath of stereom. In a few cases among the Phanerogams (e.g., *Auricula*)

a polystelic condition originates secondarily in evolution by the association of supplementary internal inversely oriented bundles with detached arcs of the original stele. This is another method of increasing the vascular supply to the leaves when the needs of these exceed the capacity of the original dilated and broken central cylinder. In other cases polystely may originate in a completely astelic type by the association of bundles round common centres (*Nymphaea*).

In the foregoing description of the evolution of the stellar

system in vascular plants, account has been taken only of what seem the principal and more easily interpreted lines of descent. Among some of the Pteridophytes (*Selaginella*), a type of polystely is found which is not directly traceable to the breaking up of a primitive siphonostele by the crowding of leaf-gaps. Among the Cycadofilices also, a great group of extinct forms occupying the borderland between Ferns and Gymnosperms, side by side with monostelic types which furnish a most interesting sequence leading from the protostele so common among modern Pteridophytes to the modified siphonostele characteristic of modern Cycads, Conifers, and Dicotyledons, there are a number of siphonostelic and polystelic types (the *Medulloseæ* and allied forms) in which the breaking of the siphonostele does not depend upon the departure of leaf-traces. The structures presented are often of considerable complexity, and their origin and relationship with the more easily intelligible types are frequently obscure.

In the blade of a typical leaf of a vascular plant—essentially a thin plate of assimilating tissue—the vascular system takes the form of a number of separate, usually branching and anastomosing strands. These with their associated stereom form a kind of framework which is of great importance in supporting the mesophyll; but also, and chiefly, they provide a number of channels, penetrating every part of the leaf, along which water and dissolved salts are conveyed to, and elaborated food-substances from, the mesophyll cells. Each bundle is a branch of an original meristele that left the cylinder of the stem. It is always collateral (the phloem being turned downwards and the xylem upwards), even in Ferns, where the meristele or meristemes of the petiole (“petiolar steles”) are concentric, and it has the ordinary mesoderm and periderm of the collateral bundle. The latter is often sclerized, especially opposite the phloem, and to a less extent opposite the xylem, as in the stem. As a bundle is traced towards its blind termination in the mesophyll the peridermic stereom first disappears, the sieve-tubes of the phloem are replaced by narrow elongated parenchyma cells, which soon die out, and the bundle ends with a strand of tracheids covered by the phlootermic sheath.

The structure of the stele of the primary root as it is found in most Pteridophytes and many Phanerogams has been already described (Fig. 2). The radial structure is characteristic of all root-steles, which have in essential points a remarkably uniform structure throughout the vascular plants, a fact which is no doubt largely dependent on the very uniform conditions under which they live. The larger root-steles are usually polyarch, and seldom have the centre filled up with xylem, this being replaced by a large-celled pith so that the siphonostelic structure is acquired (Fig. 9). Sometimes, however, the centre of a bulky root stele has strands of metaxylem (to which may be added strands of metaphloem) scattered through it, the interstices being filled with conjunctive. The conjunctive of a root-stele possessing a pith is often sclerized between the pith and the pericycle. Sometimes all the parenchyma within the stele undergoes this change. In the roots of some palms the siphonostele breaks up into arcs, which may each acquire a “stellar” structure by the bending in and joining of the edges.

For “laticiferous tissue,” see CYTOLOGY.

The body of a vascular plant is developed in the first place by repeated division of the fertilized egg and the growth of the products of division. The body thus formed is called the *embryo*, and this develops into the adult plant, not by continued growth of all its parts as in an animal, but by localization of the regions of cell-division and growth, such a localized region being called a *growing-point*. This localization takes place first at the two free ends of the primary axis, the descending part of which is the primary root, and the ascending the primary shoot. Later, the axis branches by the formation of new growing-points, and in this way the complex branch system of axes forming the body of the ordinary vascular plant is built up. In the flowering plants the embryo, after developing up to a certain point, stops growing and rests, enclosed within the *seed*. It is only on germination of the latter that the development of the embryo into the free plant is begun. In the Pteridophytes, on the other hand, development from the egg is continuous.

The triple division of tissues is laid down in most cases at a very early period of development—in the flowering plants usually before the resting stage is reached. In many Pteridophytes the first leaf is formed very early, and the first vascular strand is

developed at its base, usually becoming continuous with the cylinder of the root; the strand of the second leaf is formed in a similar way, and runs down to join that of the first, so that the stem stele is formed by the joined bases of the leaf-traces. In other cases, however, a continuous primitive stele is developed, extending from the primary stem to the primary root, the leaf-traces arising later. This is correlated with the comparatively late formation and small development of the first leaves. The evidence scarcely admits of a decision as to which of these methods is to be regarded as primitive in descent. In the seed-forming plants (*Phanerogams*) one or more primary leaves (*cotyledons*) are already formed in the resting embryo. In cases where the development of the embryo is advanced at the resting period, traces run from the cotyledons and determine the symmetry of the stele of the primitive axis, the upper part of which shows stem-structure, in some respects at least, and is called the hypocotyledonary stem or *hypocotyl*, while the lower part is the primary root (*radicle*). On germination of the seed the radicle first grows out, increasing in size as a whole, and soon adding to its tissues by cell division at its apical growing-point. The hypocotyl usually elongates by its cells increasing very greatly both in number and size, so that the cotyledons are raised into the air as the first foliage-leaves. Further growth in length of the stem is thenceforward confined to the apical growing-point situated between the cotyledons. In other cases this growing-point becomes active at once, there being little or no elongation of the hypocotyl and the cotyledon or cotyledons remaining in the seed.

The structure of the growing-points or apical meristems varies much in different cases. In most Pteridophytes there is a single large *apical cell* at the end of each stem and root axis.

This usually has the form of a tetrahedron, with its base occupying the surface of the body of the axis and its apex pointing towards the interior. In the stem, segments are successively cut off from the sides of the tetrahedron, and by their subsequent division the body of the stem is produced. In the root exactly the same thing occurs, but segments are cut off also from the base of the tetrahedron, and by the division of these the root-cap is formed. In both stem and root early walls separate the cortex from the stele. The epidermis in the stem and the surface layer of the root soon becomes differentiated from the underlying tissue. In some Pteridophyte stems the apical cell is wedge-shaped, in others prismatic; in the latter case segments are cut off from the end of the prism turned towards the body of the stem. In other cases, again, a group of two or four prismatic cells takes the place of the apical cell. Segments are then cut off from the outer sides of these *initial cells*. In most of the Phanerogams the *apical* (or *primary*) *meristem*, instead of consisting of a single apical cell or a group of initials, is stratified—i. e., there is more than one layer of initials. Throughout the Angiosperms the epidermis of the shoot originates from separate initials, which never divide tangentially, so that the young shoot is covered by a single layer of dividing cells, the *dermatogen*. Below this are the initials of the cortex and central cylinder. Whether these are always in layers which remain separate is not known, but it is certain that in many cases they cannot be distinguished. This, however, may be due to irregularity of division and displacement of the cells by irregular tensions destroying the obvious layered arrangement. In some cases there is a perfectly definite line of separation between the young cylinder (*plerome*) and young cortex (*periblem*), the latter having one or more layers of initials at the actual apex. This clear separation between periblem and plerome is mostly found in plants whose stem-apex forms a naked cone, the leaves being produced relatively late, so that the stele of the young stem is obvious above the youngest leaf-traces. Where the leaves are developed early, they often quite overshadow the actual apex of the stem, and the rapid formation of leaf tissue disturbs the obviousness of, and perhaps actually destroys, the stratified arrangement of the shoot initials. In this case also, the differentiation of leaf-bundles, which typically begins at the base of the leaf and extends upwards into the leaf and downwards into the stem, is the first phenomenon in the development of vascular tissue, and is seen at a higher level than the formation of a stele. The latter is produced (except in cases of complete astely where a cylinder is never formed) after a number of leaf-traces have appeared on different sides of the stem so as to form a circle as seen in transverse section, the spaces intervening between adjacent bundles becoming bridged by small-celled tissue closing the cylinder. In this tissue fresh bundles may become differentiated, and what remains of it becomes the rays of the fully-formed stele. Many cases exist which are intermediate between the two extreme types described. In these the stele becomes obvious in transverse section at about the same level as that at which the first leaf-traces are developed. Where a large-celled pith is developed this often becomes obvious very early, and in some cases it appears to have separate initials situated below those of the hollow vascular cylinder or modified siphonostele.

Growing-points.

In some cases where there is apparently a well-marked plerome at the apex, this is really the young pith, the distinction between the stelar and cortical initials, if it exists, being, as is so often the case, impossible to make out. The young tissue of the stelar cylinder, in the case of the modified siphonostele characteristic of the dicotyledonous stem, differs from the adjoining pith and cortex in its narrow elongated cells, produced by the stopping of transverse and the increased frequency of longitudinal divisions. This is especially the case in the young vascular bundles themselves (*desmogen strands*). The protoxylem and protophloem are developed a few cells from the inner and outer margins of the desmogen strand, desmogenic tissue left over giving rise to the segments of endocycle and pericycle capping the bundle. Differentiation of the xylem progresses outwards, of the phloem inwards, but the two tissues never meet in the centre. Sometimes development stops altogether, and a layer of undifferentiated parenchyma, the *mesodesm*, is left between them; or it may continue indefinitely, the central cells keeping pace by their tangential division with the differentiation of tissue on each side. In this case the formation of the primary bundle passes straight over into the formation of secondary tissue by a cambium, and no line can be drawn between the two processes. The differentiation of the stelar stereom, which usually takes the forms of a sclerized pericycle, and may extend to the endocycle and parts of the rays, takes place in most cases later than the formation of the primary vascular strand. In the very frequent cases where the bundles have considerable individuality, the fibrous pericyclic cap very clearly has a common origin from the same strand of tissue as the vascular elements themselves.

The separation of layers in the apical meristem of the root is usually very much more obvious than in that of the stem. The outermost is the *calyptragen*, which gives rise to the root cap, and in Dicotyledons to the piliferous layer as well. The *periblem*, one cell thick at the apex, produces the cortex, to which the piliferous layer belongs in Monocotyledons; and the *plerome*, which is nearly always sharply separated from the periblem, gives rise to the vascular cylinder. In a few cases the boundaries of the different layers are not traceable. The protoxylems and the phloem strands are developed alternately, just within the outer limit of the young cylinder. The differentiation of metaxylem follows according to the type of root-stele, and, finally, any stereom there may be is developed. Differentiation is very much more rapid—*i.e.*, the tissues are completely formed much nearer to the apex than is the case in the stem. This is owing to the elongating region (in which protoxylem and protophloem alone are differentiated) being very much shorter than in the stem. The root hairs grow out from the cells of the piliferous layer immediately behind the elongating region.

The branches of the stem arise by multiplication of the cells of the epidermis and cortex at a given spot, giving rise to a protuberance, at the end of which an apical meristem is established. The vascular system is connected in various ways with that of the parent axis by the differentiation of bundle-connexions across the cortex of the latter. This is known as *exogenous* branch-formation. In the root, on the other hand, the origin of branches is *endogenous*. The cells of the pericycle, usually opposite a protoxylem strand, divide tangentially and give rise to a new growing-point. The new root thus laid down burrows through the cortex of the mother-root and finally emerges into the soil. The connexions of its stele with that of the parent axis are made across the pericycle of the latter. Its cortex is never in connexion with the cortex of the parent, but with its pericycle. *Adventitious roots*, arising from the stems, usually take origin in the pericycle, but sometimes from other parts of the conjunctive.

In most of the existing Pteridophytes, in the Monocotyledons, and in annual plants among the Dicotyledons, there is no further growth of much structural importance in the tissues after differentiation from the primary meristems. But in nearly all perennial Dicotyledons, in all dicotyledonous and gymnospermous trees and shrubs, and in fossil Pteridophytes belonging to all the great groups, certain layers of cells remain meristematic among the permanent tissues, or after passing through a resting stage reacquire meristematic properties, and give rise to *secondary tissues*. Such meristematic layers are called *secondary meristems*. There are two chief secondary meristems, the *cambium* and the *phellogen*. The formation of secondary tissues is characteristic of most woody plants, to whatever class they belong. Every great group or phylum of vascular plants, when it has become dominant in the vegetation of the world, has produced members with the tree habit arising by the forma-

tion of a thick woody trunk, in most cases by the activity of a cambium.

The *cambium* in the typical case, which is by far the most frequent, continues the primary differentiation of xylem and phloem in the desmogen strand (see above), or arises in the resting mesodesm or mesocycle and adds new (secondary) xylem and phloem to the primary tissues. New tangential walls arise in the cells which are the seat of cambial activity, and an *initial layer* of cells is established which cuts off *tissue-mother-cells* on the inside and outside, alternately contributing to the xylem and the phloem. A tissue-mother-cell of the xylem may, in the most advanced types of Dicotyledons, give rise to—(1) a tracheid; (2) a segment of a vessel; (3) a xylem-fibre; or (4) a vertical file of xylem-parenchyma cells. In the last case the mother-cell divides by a number of horizontal walls. A tissue-mother-cell of the phloem may give rise to—(1) a segment of a sieve-tube with its companion cell or cells; (2) a phloem-fibre; (3) a single phloem-parenchyma (cambiform) cell, or a vertical file of short parenchyma cells. At certain points the cambium does not give rise to xylem and phloem elements, but cuts off cells on both sides which elongate radially and divide by horizontal walls. When a given initial cell of the cambium has once begun to produce cells of this sort it continues the process, so that a radial plate of parenchyma cells is formed stretching in one straight line through the xylem and phloem. Such a cell-plate is called a *medullary ray*. It is essentially a living tissue, and serves to place all the living cells of the secondary vascular tissues in communication. It conducts plastic substances inwards from the cortex, and its cells are frequently full of starch, which they store in winter. They are accompanied by intercellular channels serving for the conduction of oxygen to, and carbon dioxide from, the living cells in the interior of the wood, which would otherwise be cut off from the means of respiration. The xylem and phloem parenchyma consist of living cells, fundamentally similar in most respects to the medullary ray cells, which sometimes replace them altogether. The parenchyma is often arranged in tangential bands between the layers of sieve-tubes and tracheal elements. The xylem parenchyma is often found in strands associated with the tracheal elements. These strands are not isolated, but form a connected network through the wood. The xylem-parenchyma cells are connected, as are the medullary ray cells, with the tracheal elements by one-sided bordered pits—*i.e.*, pits with a border on the tracheal element side, and simple on the parenchyma cell side. The fibres are frequently found in tangential bands between similar bands of tracheæ or sieve-tubes. The fibrous bands are generally formed towards the end of the year's growth in thickness. The fibres belong to the same morphological category as the parenchyma, various transitions being found between them; thus there may be thin-walled cells of the shape of fibres, or ordinary fibres may be divided into a number of superposed cells. These intermediate cells, like the ordinary parenchyma, frequently store starch, and the fibres themselves, though usually dead, sometimes retain their protoplasm, and may also be used for starch accumulations. The vessels and tracheids are very various in size, shape, and structure in different plants. They are nearly always aggregated in strands, which, like those of the parenchyma, are not isolated, but connected with one another. In a few cases some of the tracheids have very thick walls and reduced cavities, functioning as mechanical rather than water-conducting elements. All transitions are found between such forms and typical tracheids. These *fibre-tracheids* are easily confused on superficial view with the true wood-fibres belonging to the parenchymatous system; but their pits are always bordered, though in the extreme type they are reduced to mere slits in the wall. The sieve-tubes of the secondary phloem usually have very oblique end-walls bearing a row of sieve-plates; plates also occur on the radial side-walls.

The tissue-elements just described are found only in the more complicated secondary vascular tissues of certain Dicotyledons. A considerable evolution in complexity can be traced in passing from the simplest forms of xylem and phloem found in the primary vascular tissues both among Pteridophytes and Phanerogams to these highly differentiated types. In the simplest condition we have merely tracheæ and sieve-tubes, respectively associated with parenchyma, which in the former case is usually amyloem, and in the latter consists of proteid cells. This type is found in nearly all Pteridophytes and, so far as is known, in Cycadoflites, both in primary and secondary tissue. The stereom is furnished either by cortical cells or by the tracheal elements, in a few cases by fibres which are probably homologous with sieve-tubes. Among Gymnosperms the secondary xylem is similarly simple, consisting of tracheids which act as stereom as well as hydrom, and a little amyloem; while the phloem-parenchyma sometimes undergoes a differentiation, part being developed as amyloem, part as proteid cells immediately associated with the sieve-tube. In other cases the proteid cells of the secondary

phloem do not form part of the phloem-parenchyma, but occupy the top and bottom cell-rows of the medullary rays, the middle rows consisting of ordinary starchy cells. The top and bottom rows of the xylem rays are often developed as irregularly-thickened radially-elongated tracheids which serve for the radial conduction of water, and communicate with the ordinary tracheids of the secondary xylem by large bordered pits. The primary vascular tissues of Angiosperms are likewise nearly always simple, consisting merely of tracheæ and sieve-tubes often associated with amyloem. A characteristic peculiarity, both in the primary and secondary tissue, is that the proteid cells of the phloem are here always sister-cells of the leptoids and are known as *companion-cells*. In the secondary tissues of Dicotyledons we may have, as already described, considerably more differentiation of the cells, all the varieties being referable, however, on the one hand to the tracheal or sieve-tube type, on the other to the parenchyma type. The main feature is the development of special vascular stereom and storage tissue. In some cases special secreting tissues, resin ducts, oil glands, laticiferous tissue, crystal sacs, &c., may be developed among the ordinary secondary vascular elements.

The limit of each year's increment of secondary wood, in those plants whose yearly activity is interrupted by a regular winter or dry season, is marked by a more or less distinct line, which is produced by the sharp contrast between the wood formed in the late summer of one year (characterized by the sparseness or small diameter of the tracheal elements, or by the preponderance of fibres, or by a combination of these characters, giving a denseness to the wood) and the loose spring wood of the next year, with its absence of fibres, or its numerous large tracheæ. The abundance of water-conducting channels is in relation to the need for a large and rapid supply of water to the unfolding leaves in the spring and early summer. In Gymnosperms, where vessels and fibres are absent, the late summer wood is composed of radially narrow thick-walled tracheids, the wood of the succeeding spring being wide-celled and thin-walled, so that the limit of the year's growth is very well marked. The older wood of a large tree forming a cylinder in the centre of the trunk frequently undergoes marked changes in character. The living elements die, and the walls of all the cells often become hardened, owing to the deposit in them of special substances. Wood thus altered is known as heart-wood, or *duramen*, as distinguished from the young sap-wood, or *alburnum*, which, forming a cylinder next the cambium, remains alive and carries on the active functions of the xylem, particularly the conduction of water. The heart-wood ceases to be of any use to the tree except as a support, but owing to its dryness and hardness it alone is of much use for industrial purposes. The great hardness of teak is due to the silica deposited in the heart-wood, and the special colouring matters of various woods, such as yellow wood, ebony, &c., are confined to the heart-wood. In some cases the heart-wood, instead of becoming specially hard, remains soft and easily rots, so that the trunk of the tree frequently becomes hollow, as is commonly the case in the willow. Heart-wood is first formed at very different epochs in the life of a tree, according to the species—*e.g.*, after fifteen to twenty years in the oak, forty years in the ash, etc.

In many annual plants no cambium is formed at all, and the same is true of most perennial Pteridophytes and Monocotyledons.

When the vascular tissue of such plants is arranged in separate bundles these are said to be *closed*. The bundles of plants which form cambium are, on the contrary, called *open*. In stems with open bundles the formation of cambium and secondary tissue may be confined to these, when it is said to be entirely *fascicular*. In that case either very little secondary tissue is formed, as in the gourds, some Ranunculaceæ, &c., or a considerable amount may be produced (clematis, barberry, ivy). In the latter event the cells of the primary rays are either merely stretched radially, or they divide to keep pace with the growth of the bundles. If this division occurs by means of a localized secondary meristem connecting the cambial layers of adjacent bundles, an *interfascicular* is formed in addition to the fascicular cambium. The interfascicular cambium may form nothing but parenchymatous tissue, producing merely continuations of the primary rays. Such rays are usually broader and more conspicuous than the secondary rays formed within the wedges of wood opposite the primary bundles, and are distinguished as *principal rays* from these narrower *sub-ordinate* or *fascicular rays*. This is the typical case in most trees where the primary bundles are close together. Where the primary bundles are farther apart, so that the primary rays are wider, the interfascicular cambium may form several fairly broad (principal) secondary rays in continuation of certain radial bands of the primary ray, and between these, wedges of secondary xylem and phloem: or, finally, secondary xylem and phloem may be formed by the whole circumference of the cambium, fascicular and interfascicular alike, interrupted only by narrow secondary rays, which have no relation to the primary ones.

In a good many cases, sometimes in isolated genera or species, sometimes characteristic of whole families, so-called anomalous cambial layers are formed in the stem, either as an extension of, or in addition to, the original cambial cylinder. They are frequently associated with irregularities in the activity of the original cambium. Irregularity of cambium occurs in various families of woody dicotyledonous plants, mostly among the woody climbers, known as *lianes*, characteristic of tropical and sub-tropical forests. In the simplest cases the cambium produces xylem more freely along certain tracts of the circumference than along others, so that the stem loses its original cylindrical form and becomes elliptical or lobed in section. In others the secondary phloem is produced more abundantly in those places where the xylem is deficient, so that the stem remains cylindrical in section, the phloem occupying the bays left in the xylem mass. Sometimes in such cases the cambium ceases to be active round these bays and joins across the outside of the bay, where it resumes its normal activity, thus isolating a phloem lake, or, as it is usually called, a *phloem island*, in the midst of the xylem. The significance of these phenomena, which present many minor modifications in different cases, is not fully understood; but one purpose of the formation of phloem promontories and islands seems to be the protection of the sieve-tubes from crushing by the often considerable peripheral pressure that is exercised on the stems of these lianes. Sometimes the original cambial ring is broken into several arcs, each of which is completed into an independent circle, so that several independent secondary vascular cylinders are formed. The formation of additional cambial cylinders or bands occurs in the most various families of Dicotyledons and in some Gymnosperms. They may arise in the pericycle or endocycle of the stele, in the cortex of the stem, or in the parenchyma of the secondary xylem or phloem. The activity of the new cambium is often associated with the stoppage of the original one. Sometimes the activity of the successive cambiums simply results in the formation of concentric rings or arcs of secondary xylem and phloem. In other cases a most intricate arrangement of secondary tissue masses is produced, quite impossible to interpret unless all stages of their development have been followed. Sometimes in lianes the whole stem breaks up into separate woody strands, often twisted like the strands of a rope, and running into one another at intervals. An ordinary cambium is scarcely ever found in the Monocotyledons, but in certain woody forms a secondary meristem is formed outside the primary bundles, and gives rise externally to a little secondary cortex, and internally to a secondary parenchyma in which are developed numerous zones of additional bundles, usually of concentric structure, with phloem surrounded by xylem.

The cambium in the root, which is found generally in those plants which possess a cambium in the stem, always begin in the conjunctive tissue internal to the primary phloems, and forms new (secondary) phloem in contact with the primary, and secondary xylem internally. In roots which thicken but slightly, whose cambium usually appears late, it is confined to these regions. If the development of secondary tissues is to proceed further, arcs of cambium are formed in the pericycle external to the primary xylems, and the two sets of cambial arcs join, forming a continuous, wavy line on transverse section, with bays opposite the primary phloems and promontories opposite the primary xylems. Owing to the resistance offered by the hard first-formed secondary xylem, the bays are pushed outwards as growth proceeds, and the wavy line becomes a circle. Opposite the primary xylems, the cambium either (*a*) forms parenchyma on both sides, making a broad, secondary (principal) ray, which interrupts the vascular ring and is divided at its inner extremity by the islet of primary xylem; or (*b*) forms secondary xylem and phloem in the ordinary way, completing the vascular ring. In either case, narrow, secondary rays are formed at intervals, just as in the stem. Thus the structure of an old thickened root approximates to that of an old thickened stem, and so far as the vascular tissue is concerned can often only be distinguished from the latter by the position and orientation of the primary xylems. The cambium of the primary root, together with the tissues which it forms, is always directly continuous with that of the primary stem, just in the same way as the tissues of the primary stele. The so-called anomalous cambiums in roots follow the same lines as those of the stem.

In nearly all plants which produce secondary vascular tissues by means of a cambium there is another layer of secondary meristem arising externally to, but in quite the same fashion as, the cambium, and producing like the latter an external and an internal secondary tissue. This is the *phellogen*, and the whole of the tissue it gives rise to is known as *periderm*. The phellogen derives its name from the fact that its external product is the characteristic tissue known as *cork*. This consists typically of closely-fitting layers of cells with completely suberized walls,

Cambium in roots.

Phellogen and periderm.

intended to replace the epidermis as the external protective layer of the plant when the latter, incapable as it is of further growth after its original formation, is broken and cast off by the increase in thickness of the stem through the activity of the cambium. Cork is also formed similarly in the root after the latter has passed through its primary stage as an absorptive organ, and has its structure assimilated to that of the stem. The internal tissue formed by the phellogen is known as *phellogen*, and consists usually of ordinary parenchyma. The phellogen may arise, in the first place, in any tissue of the axis external to the actual vascular tissues—*i.e.*, in the epidermis itself (rarely), in any layer of the cortex, or in the pericycle. Its most usual seat of origin in the stem is the external layer of the cortex immediately below the epidermis; in the root, the pericycle. All the tissues external to the cork are cast off by the plant. The extent of development of the phellogen is dependent upon whether the phellogen has a superficial or a deep-seated origin. In the former case the formation of phellogen is trivial in amount; in the latter, considerable, since this tissue has to replace the cast-off cortex, as a metabolic and particularly a storage tissue. Provision is made for gaseous interchange between the internal tissues and the external air after the formation of cork, by the development of *lenticels*. These are special organs which interrupt the continuity of the impermeable layer of ordinary cork-cells. A lenticel is formed by the phellogen at a given spot dividing very actively and giving rise to a loose tissue of rounded cells which soon lose their contents, and between which air can pass to the tissues below. A lenticel appears to the naked eye as a rounded or elongated scar, often forming a distinct prominence on the surface of the organ. The lenticels of the stem are usually formed beneath stomata, whose function they take up after the stomata have been ruptured and cast off with the rest of the epidermis. Both cork and phellogen may be differentiated in various ways. The former often has its cells lignified, and may consist of alternate layers of hard and soft cells. The latter may develop stereom, and may also be the seat of origin of new formations of various kinds—*e.g.*, supplementary vascular bundles, anomalous cambial zones, etc. It is often enormously developed and forms a very important tissue in roots. In the stem of a tree the original phellogen is replaced by successive new phellogenic layers of deeper and deeper origin, each forming its own layer of cork. Eventually the new phellogens reach the level of the secondary phloem, and are formed in the parenchyma of the latter, keeping pace in their inward march with the formation of fresh secondary phloem by the cambium. The complex system of dead and dying tissues cut off by these successive periderms, together with the latter themselves—in fact, everything outside the innermost phellogen, constitutes what is often known botanically as the *bark* of the tree. *Rhytidome* is, however, a preferable term, as the word bark has long been established in popular usage to mean all the tissue that can easily be peeled off—*i.e.*, everything down to the wood of the tree. The rough surface of the bark of many trees is due to the successive phellogens not arising in regular concentric zones, but forming in arcs which join with the earlier-formed arcs, and thus causing the bark to come off in flakes or thick chunks. A layer of cork is regularly formed in most Phanerogams across the base of the petiole before leaf fall, so as to cover the wound caused by the separation of the leaf from the stem. Special “wound-cork” is also often formed round accidental injuries so as to prevent the rotting of the tissues by the soaking in of rain and the entrance of fungal spores and bacteria. A peculiar modification of periderm is formed by the phellogen in the submerged organs (roots or stems) of many aquatic or marsh-loving plants. This may take various forms and may cover the whole of the organ or be localized in special regions; but its cells are always living and are separated by very large intercellular spaces. This tissue is called *aerenchym*, and no doubt its function is to facilitate the respiration of the organs on which it is formed and to which the access of oxygen is difficult. In other cases, a similar formation of spongy but dead periderm cells may occur for the same purpose in special patches, called *pneumatodes*, on the roots of certain trees living in marshy places, which rise above the soil in order to obtain air.

History and Bibliography.—The study of plant anatomy was begun in the middle of the seventeenth century as a direct result of the construction of microscopes, with which a clear view of the structure of plant tissues could be obtained. The Englishman Grew and the Italian Malpighi almost simultaneously published illustrated works on the subject, in which they described, for the most part very accurately, what they saw with the new instruments. The subject was practically dormant for nearly a century and a half, largely owing to the dominance of classificatory botany under the influence of Linnæus. It was revived by several German workers, prominent among whom were Treviranus and Link, and later Moldenhawer, as well as by the Frenchman Mirbel, at the beginning of the nineteenth century. The new work largely centred round a discussion of the nature and origin of *vessels*,

conspicuous features in plant tissues which acquired an importance quite out of proportion to their real place in the construction of the vascular plant. The whole of the writings of this time are dominated by a preoccupation with the functions of the different tissues, in itself an excellent standpoint for investigation, but frequently leading in the case of these early investigators to one-sided and distorted views of the facts of structure. The pioneer of modern plant anatomy was Hugo von Mohl (*fl.* 1840), who carefully investigated and described the facts of anatomical structure without attempting to fit them into preconceived views of their meaning. He produced a solid body of accurately described facts which has formed the secure groundwork of subsequent advance. From Mohl down to the eighth decade of the century the study of anatomy was entirely in the hands of a group of German investigators, prominent in which are the names of several of the most eminent founders of modern scientific botany—such, for instance, as Nägeli, Sanio, and De Bary. To the first we owe the secure foundation of our knowledge of the structure and course of the vascular strands of the higher plants (“*Ueber den Bau und die Anordnung der Gefässbündel bei den Stamm und Wurzel der Phanerogamen.*” *Beiträge zur Wissenschaftlichen Botanik*, Heft 1, Leipzig, 1859); to the second the establishment of the sound morphological doctrine of the central cylinder of the axis as the starting-point for the consideration of the general arrangement of the tissues, and the first clear distinction between primary and secondary tissues (*Botanische Zeitung*, 1861 and 1863); to the last the putting together of the facts of plant anatomy known up to the middle of the eighth decade of the century in that colossal encyclopædia of plant anatomy, the *Vergleichende Anatomie der Vegetationsorgane bei den Phanerogamen und Farnen*, Stuttgart, 1876. (English translation: *Comparative Anatomy of the Vegetative Organs of the Phanerogams and Ferns*, Oxford, 1882.) In 1870-71, Van Tieghem published his great work, “*Sur la Racine.*” *Ann. Sci. Nat. Bot.*, Paris. This was not only in itself an important contribution to plant anatomy, but served as the starting-point of a series of researches by Van Tieghem and his pupils, which have considerably advanced our knowledge of the details of histology, and also culminated in the foundation of the doctrine of the stele (Van Tieghem and Douliot, “*Sur la Polystélie.*” *Ann. Sci. Nat. Bot.* 1887; Van Tieghem, *Traité de Botanique*, 2nd ed. Paris, 1889-91), which has had a most important effect on the development in recent years of morphological anatomy. In the progress of the last quarter of a century, since the publication of De Bary’s great work, four main lines of advance can be distinguished. First, the knowledge of the details of histology has of course advanced greatly in every direction through the ceaseless activity of very numerous, but mainly German, workers, though no fundamentally new types of tissue have been discovered. Secondly, the histology of fossil plants, particularly woody plants of the carboniferous period, has been placed on a sound basis, assimilated with general histological doctrine, and has considerably enlarged our conceptions of plant anatomy as a whole, though again without revealing any entirely new types of structure. This branch of the subject, founded by Corda, Göppert, Stenzel and others in Germany, was enormously advanced by Williamson’s work on the Coal Measures plants, recorded in the magnificent series of memoirs, “*Researches on the Organization of Fossil Plants of the Coal Measures.*” *Phil. Trans. Roy. Soc.* i.-xix., 1871-93. The work of Solms Laubach in Germany, Renault and Bertrand in France, and in quite recent years, of Zeiller in France, and Scott and Seward in England, has advanced our knowledge of the anatomy of fossil plants in an important degree. While convincing us that the plants of past ages in the earth’s history were exposed to very similar conditions of life, and made very much the same adaptive responses as their modern representatives, one of the main results of this line of work has been to reveal important data enabling us to fill various gaps in our morphological knowledge and to obtain a more complete picture of the evolution of tissues in the vascular plants. One of the most striking incidents in the progress has been the recognition within the last few years of the existence of an extinct group of plants lying on the borderland between Ferns and Gymnosperms, and known as the Cycadofilices, a group in which, curiously enough, the reproductive organs have not yet been discovered, but the anatomy of whose members affords sufficient evidence of their true affinities. Thirdly, we have to record very considerable progress in our knowledge of that distinctively morphological anatomy to which reference was made in the introduction to this article. The Russian plant-anatomist, Russow, may be said to have founded the consideration of plant tissues from the point of view of descent (*Vergleichende Untersuchungen über die Leitbündelkryptogamen*. St Petersburg, 1872; and *Betrachtungen über Leitbündel und Grundgewebe*. Dorpat, 1875). He has been ably followed by Strasburger (*Ueber den Bau und die Verrichtungen der Leitungsbahnen in den Pflanzen*, Jena, 1891), Haberlandt and others. The explicit adoption of this point of view has had

the effect of clearing up and rendering definite the older morphological doctrines, which for the most part had no fixed criterion by which they could be tested. This has been conspicuously the case with regard to Van Tieghem's famous doctrine of the *stèle*, which has quite lately been severely criticised from this point of view in England and America, where morphological anatomy is at the present time being actively pursued by Scott, Gwynne-Vaughan, Jeffrey, and others. Fourthly, we have to record the

foundation of the modern study of physiological anatomy by Schwendener (*Das mechanische Princip im Bau der Monocotylen*, 1874, and other works), followed by numerous pupils and others, among whom Haberlandt (*Physiologische Pflanzen-Anatomie*, Leipzig, 1st ed. 1884, 2nd ed. 1896, and other works) is pre-eminent. The pursuit of this study has not only thrown valuable light on the economy of the plant as a whole, but forms an indispensable condition of the advance of morphological anatomy.

(A. G. T.)

Anazarba, *Anazàrbus* or *Cæsarea ad Anazarbum*, the metropolis of Cilicia Secunda, situated N.E. of Adana in the rich Cilician plain at the foot of an isolated ridge of rock upon which stood its acropolis. In the 12th century it was for a time the capital of Lesser Armenia, and its ruins are striking and interesting.

Ancachs, a coast department of central Peru, with an area of 16,562 square miles, and a population officially estimated at 428,703. It embraces seven provinces, Santa, with the town of Santa (population, 3000); Pallasca, with the town of Samanco (2000); Pomabamba, with the town of Huarney (1500); Huaraz, with the town of Huaraz (8000); Huaylas, with the town of Huaylas (6000); Huari, and Cajartambo. In the sierra are the important towns of Caraz (6000) and Carhuaz (5000).

Anchor, the instrument which, secured to a ship by a cable, enables her to ride in safety, and therefore forms one of the most important articles in the vessel's equipment. Until the beginning of the 19th century anchors were of imperfect manufacture, the means of effecting good and efficient welding being absent and the iron poor, whilst the arms, being straight, generally parted at the crown, when weighing from good holding ground. Mr Pering in the early part of the century introduced curved arms; and twenty-five years later, the

FIG. 1.—Improved Martin Anchor.

Admiralty anchor, under the direction of the Board, was supplied to H.M. ships, followed by Lieutenant (after-

wards Captain) Rodger's anchor, with well-formed arms, shank, and crown, the points or pees to the palm being blunt. This anchor had an excellent reputation amongst nautical men of that period. The Committee on Anchors, appointed by the Admiralty in 1852, placed at the head of the list Trotman and Rodger's anchors. In the former a great departure from previous anchors was made, the arms in one piece pivoted on a bolt through a fork-shaped shank; later came the self-canting and close-stowing Martin anchor,

FIG. 2.—Improved Martin-Adelphi Anchor.

which, passing through successive improvements in design and manufacture, is largely used in the Royal Navy and mercantile marine.

The improved Martin anchor (Fig. 1) is made of forged iron; a projection in the centre of the arms works in a recess at the heel of the shank; the arms when in position are secured by side plates close to the heel of the shank; the vacancies outside the shank are filled by blocks bolted through on each side and are flush with the side plates, the latter keeping the flukes in position. The introduction of cast-steel in 1894 led to the improved Martin-Adelphi pattern (Fig. 2). The crown and arms are cast in one, and, with the stock, are made of cast-steel, the shank remaining of forged iron; a projection in the crown works in a recess (lower Fig. 2), secured in its place by a forged

FIG. 3.—Hall's Stockless Anchor.

FIG. 3a.—Hall's Stockless Anchor stowed.

steel pin passing through crown and heel of shank; a nut with washer is fitted to the pin. Stockless anchors are extensively used in the British mercantile marine and in some foreign navies; their advantages are—handiness, absence of davits, and a clear fore-castle for right ahead gun fire or for working ship. Should experience prove that a stockless anchor possesses the same holding power as a stocked one, it will supersede the latter. Hall's stockless anchor is shown in Figs. 3 and 3a, and Riley's in Fig. 4. The latter is made in three pieces

FIG. 4.—Riley's Stockless Anchor.

—a shank, a fast fluke, and a loose one; the fast fluke has a square end cast on the neck, and is passed through the shank, and the loose one is riveted and pinned on to the square end; a deep vertical rib or flange is cast at the back of the flukes, and, together with the stops on the shank, serves to tilt the flukes at an angle for taking the ground. To stow an anchor in a modern

FIG. 5.—Anchor stowed.

man-of-war it is hove up close to the forefoot, and the inner end of a ground chain which is stopped and secured to the cable will be inside the hawse pipe, whilst its outer end is secured to a balancing (gravity) band, consisting of an iron strap and shackle on the shank of the anchor. Before weighing, the outer end of the catting chain is rove through an iron leading block on the cat davit, and the iron swivel block (Fig. 5, AA) at the cat-

FIG. 6.—Anchor stowed à Cock Bill.

head, and taken in through the hawse pipe; when the inner end of the ground chain is sufficiently inboard, the ground and catting chains are joined and the latter brought to the capstan, and the anchor hoisted up horizontally and placed by the cat davit, which pivots at its base (Fig. 5, B) on the bill-board, and secured by chains; an end of each chain passing over a rod with lever for letting go;

additional chains are employed for securing at sea. For right ahead fire and for sea, the cat davit hinged (Fig. 5, B) is stowed in position indicated by the dotted line (Fig. 5, C). Ground and catting chains are being superseded in some ships by a wire pendant and cat hook, the anchor being hove close up to the hawse pipe. To avoid cutting away a portion of the forecabin, anchors are stowed à Cock Bill (Fig. 6), the crowns resting on iron shoes secured to the ship's side, the flukes being fore and aft; the cat-heads are short. To let go, the securing chains are cleared away, except the shank painters, which are freed by the rod A, actuated by the lever B; additional securing chains and bolts (EE and EE) are used for sea. A difficulty is experienced in stowing the anchor when pitching or rolling heavily. Fig. 7 illustrates an anchor

FIG. 7.—Anchor Crane.

with cat davit or anchor crane used in the P. & O. S. N. Company steamers ("India class 8000 tons"); for sea the anchor is stowed inboard by the anchor crane. The equipment of anchors for this class is: bowers—two Rodger's box stocked 58 cwt. and two Hall's stockless 66 cwt.; stream—one Hall's 28 cwt.; kedges—one Martin, 13½ cwt., two Martin, 8 cwt., and one Martin, 6 cwt. Stern, stream, and kedge anchors are usually stowed by special davits. A portable anchor suitable for small yachts is the invention of Mr Louis Moore; the shank passes through the crown of the anchor like the handle of a pickaxe, and the stock over the head of the shank; at the end of the stock are loose pawls; there are no keys or bolts, and the only fastening is for the cable; the anchor takes to pieces readily and stows snugly. In 1890 Colonel Bucknell also invented a portable anchor for small yachts. Iron buoy sinkers (Fig. 8) used by the Trinity House Corporation are from 8 to 40 cwt.; the specified weight is cast on them in large raised figures; the cast and wrought iron used is of special quality; samples are previously submitted to the engineer-in-chief.

FIG. 8.—Iron Buoy Sinker.

The tests for anchors supplied to H.M. ships are in tons proportionate to their weights in cwt.; new anchors are supplied by contractors, but repairs afterwards are made in H.M. dockyards, and by stamping a record is kept on the anchor of its repairs. In "Anchors and Cables Act, 1899," a list is given of authorized testing establishments, with their distinctive marks and charges, and testing houses for foreign-owned vessels are in table 22 of Lloyd's *Register of British and Foreign Shipping*. Cast-steel anchors, in addition to the statutory tests, are subjected to percussive, hammering, and bending tests, and are stamped "annealed steel." (J. W. D.)

Anchor (*Engraulis encrasicolus*), a fish of the herring family, easily distinguished by its deeply cleft mouth, the angle of the gape being behind the eyes. The pointed snout extends beyond the lower jaw. The fish

resembles a sprat in having a forked tail and a single dorsal fin, but the body is round and slender. The maximum length is $8\frac{1}{2}$ inches. Anchovies are abundant in the Mediterranean, and are regularly caught on the coast of Sicily, Italy, France, and Spain. The range of the species also extends along the Atlantic coast of Europe to the south of Norway. In winter it is common off Devon and Cornwall, but has not hitherto been caught in such numbers as to be of commercial importance. Off the coast of Holland in summer it is more plentiful, entering the Zuyder Zee in such numbers as to give rise to a regular and valuable fishery. It is also taken in the estuary of the Scheldt. There is reason to believe that the anchovies found at the western end of the English Channel in November and December are those which annually migrate from the Zuyder Zee and Scheldt in autumn, returning thither in the following spring; they must be held to form an isolated stock, for none come up from the south in summer to occupy the English Channel, though the species is resident on the coast of Portugal. The explanation appears to be that the shallow and land-locked waters of the Zuyder Zee, as well as the sea on the Dutch coast, become raised to a higher temperature in summer than any part of the sea about the British coasts, and that therefore anchovies are able to spawn and maintain their numbers in these waters. Their reproduction and development were first described by a Dutch naturalist from observations made on the shores of the Zuyder Zee. Spawning takes place in June and July, and the eggs, like those of the majority of marine fishes, are buoyant and transparent, but they are peculiar in having an elongated, sausage-like shape, instead of being globular. They resemble those of the sprat and pilchard in having a segmented yolk, and there is no oil globule. The larva is hatched two or three days after the fertilization of the egg, and is very minute and transparent; its further development has not been traced. In August young specimens $1\frac{1}{2}$ to $3\frac{1}{2}$ inches in length have been taken in the Zuyder Zee, and these must be held to have been derived from the spawning of the previous summer. There is no evidence to decide the question whether all the young anchovies as well as the adults leave the Zuyder Zee in autumn, but, considering the winter temperature there, it is probable that they do. The eggs have also been obtained from the Bay of Naples, and near Marseilles, also off the coast of Holland, and once at least off the coast of Lancashire. The occurrence of anchovies in the English Channel has been carefully studied at the laboratory of the Marine Biological Association at Plymouth. They were most abundant in 1889 and 1890. In the former year considerable numbers were taken off Dover in drift nets of small mesh, used for the capture of sprats. In the following December large numbers were taken together with sprats at Torquay. In November 1890 a thousand of the fish were obtained in two days from the pilchard boats fishing near Plymouth; these were caught near the Eddystone. When taken in British waters anchovies are either thrown away, or sent to the market fresh with the sprats. If salted in the proper way, they would doubtless be in all respects equal to Dutch anchovies, if not to those imported from Italy. The supply, however, is small and inconstant, and for this reason English fish-curers have not learnt the proper way of preparing them. The so-called "Norwegian anchovies" imported into England in little wooden kegs are nothing but sprats pickled in brine with bay-leaves and whole pepper. (J. T. C.)

Ancona, one of the sixty-nine provinces of the kingdom of Italy, bounded on the N. by the Province of Pesaro-Urbino; on the W. by Pesaro-Urbino and

Umbria; on the S. by the Province of Macerata; and on the E. by the Adriatic Sea. It has an area of 788 square miles and a population of (1901) 302,460. Owing largely to the *mezzadria* or *métayer* system, under which products are equally divided between the owners and the cultivators of the land, the soil is highly cultivated; and through the abundant harvests the people enjoy greater prosperity than in most of the other provinces. Fowls are largely exported to England. The silk cultivation provides occupation for the urban population, and several small cities, like Opino, Jesi, and Chiaravalle, depend almost entirely upon this industry. Another important branch of activity is the paper industry. Chiaravalle possesses one of the largest tobacco factories of the Italian *Régie*. Limestone quarries and sulphur mines supply building stone and sulphur to the regions of Central Italy. The Adriatic shore and the adjacent districts provide the wealthy with favourite summer resorts. As regards maritime trade the province possesses facilities in the port of Ancona, the canal port of Sinigaglia, and other smaller harbours chiefly used by fishing boats. Fishing is carried on by the entire coast population, which furnishes a large contingent of sailors to the Italian navy. The character of the country population is quiet and peaceable. All are fervent Roman Catholics.

Ancona, an Italian city, capital of the province of the same name, pleasantly situated upon the Adriatic about 124 miles from Bologna and more than 186 miles from Rome. The extensive works undertaken by the Italian Government in order to enlarge the fortifications and to purify some quarters of the city have considerably changed its aspect, which is now rendered more pleasing by wide streets and esplanades. The Gothic façade of the cathedral is among the most beautiful in Italy. There is a lazzaretto begun by Pope Clement XII. and finished by Pius VI., to whom is also due the finest street of the city and an arch (Porta Pia), by Vanvitelli. The chief monuments are those to Clement XII. and to Cavour. The municipal palace dates from 1270, and contains a valuable picture gallery and library. The Merchants' Guild and the Theatre of the Muses display exquisite workmanship. Several large bathing establishments, thoroughly modernized, are thronged by visitors in the summer months. The smaller triumphal arch erected near to that in honour of Trajan is dedicated to Pope Clement XIV., who reconstructed and enlarged the harbour and declared Ancona a free port (it is so no longer) in the 18th century. Its two moles and dredging works confer upon the port (which is furnished with a powerful lighthouse) great security and a considerable anchorage. There is an arsenal and a dockyard. Numbers of mercantile steamships are constructed, and important commissions are executed for the Italian navy every year. Trade has now regained its former volume, and the receipts of the Customs House are but little inferior to those of Venice. In 1898 commerce comprised 235,000 tons of seaborne and 32,000 tons of land imports; 48,000 tons of exports by sea and 23,000 tons by land; steamers visiting the port, 599 (of which 60 were British); sailing vessels, 468. Ancona is in direct steamship communication with the chief European countries, as well as with Asia Minor, Tunis, India, and South America. The chief manufactures are metallurgy (the arsenal alone employs 2000 workmen), sugar refining (1000 workmen), compressed coal, soapmaking, tanning, and silk-spinning. Though the great majority of the people belong to the monarchical party, Ancona is considered the headquarters of anarchism. According to Pliny, Ancona was founded by the Dorians about 1500 B.C. Population (1901), 56,825.

Andaman Islands.—These islands lie in the Bay of Bengal, 120 miles from Cape Negrais in British Burma. The southernmost, Little Andaman (26 miles by 16), is separated by a passage 31 miles wide from Rutland Island (11 miles long), which in turn is the southernmost of a group of five main islands together forming the Great Andaman. North of Rutland Island is South Andaman (49 miles), and for 17 miles from the north end, and parallel to the east shore of this, runs an island called Baratang. Beyond these again stretch Middle Andaman (59 miles) and North Andaman (51 miles). Between the North and Middle Andamans lies Austen Strait; between Middle Andaman and the north extremities of South Andaman and Baratang, Homfray's Strait; between South Andaman and Baratang, Middle (or Andaman) Strait; and between South Andaman and Rutland Island, Macpherson's Strait, the only one of the four navigable by ocean-going vessels. The sea all around is most difficult of navigation, but there are a number of safe harbours and anchorages around Great Andaman, and the charts generally were much improved by a survey in 1888-89, the chart resulting from which is in turn being continually amended. The whole group was completely surveyed topographically in 1883-86, when accurate maps on the scale of 2 miles to the inch were produced. The neighbourhood of Port Blair was mapped on a scale eight times as large.

Geology.—Preliminary examinations undertaken by official experts have afforded all that is yet known of the geology. The submarine ridges forming these islands contain much that is characteristic of the Arakan Yomas and formations common to the Nicobars, Sumatra, and the islands off Sumatra. The older rocks are probably early Tertiary or late Cretaceous, but there are no fossils to indicate age. The newer rocks are in the Archipelago chiefly and contain radiolarians and foraminifera. A theory of the subsidence of the islands seems established; it appears to be of recent origin and signs of its continuance are to be found at several places. Though lying along a recognized subterranean line of weakness, the islands have, since the British occupation (1858) at least, been entirely free from earthquakes of great violence, but shocks are, felt at more or less frequent intervals. Narcondam (extinct) and Barren Island are volcanoes of the general Sunda group. The sea-shells are not especially distinctive, but the land-shells are more noteworthy.

Meteorology.—Rarely affected by a cyclone, though within the influence of practically every one that blows in the Bay of Bengal, the Andamans are of the greatest importance because of the accurate information relating to the direction and intensity of storms which can be communicated from them, better than from any other point in the Bay, to the vast amount of shipping in this part of the Indian Ocean. Trustworthy information, also, regarding the weather which may be expected in the north and east of India is obtained at the islands, and this proves of the utmost value to the controllers of the great trades, dependent upon the rainfall. A well-appointed meteorological station has been established at Port Blair since 1868. Speaking generally, the climate of the Andamans themselves may be described as normal for tropical islands of similar latitude. Not only does the rainfall at one place vary from year to year, but there is an extraordinary difference in the returns for places quite close to one another. The official figures in inches for the station at Port Blair, which is situated in by far the driest part of the settlement, were:

1895.	1896.	1897.	1898.	1899.
125·64	107·28	136·41	127·22	87·01

The mean highest temperature in the shade in 1895 (April) was 90·1° F.; in 1897 (April), 94° F.; in 1899 (March), 91·8° F. The mean lowest temperature in the shade in 1895 (February) was 70·9° F.; in 1897 (January), 72·5° F.; in 1899 (February), 71·2° F. A tidal observatory has also been maintained at Port Blair since 1880.

Forests.—In the forests which cover the Great Andaman the timber available for economic purposes is both plentiful and varied, and the supply is only limited by the difficulty of obtaining labour. A section of the general forest department of India has been established in the islands, and 156 square miles have been

formally set apart for regular forest operations in the neighbourhood of Port Blair. There is, however, no indigenous labour whatever, and the working of this area is entirely carried out by the convicts in the penal settlement. There is an export trade in timber both to Calcutta and to Europe, and the Andaman Padouk is so highly valued in European markets as a substitute for mahogany that a spurious imitation known as African Padouk has been exploited. Tea is grown in considerable quantities, and the cultivation is under a department of the penal settlement. The output in 1895 was 145,203 lb; in 1897, 121,056 lb; in 1899, 154,004 lb.

Animals.—Of imported animals, cattle, goats, asses, and dogs thrive well; ponies and horses, indifferently; sheep, badly, though some success has been achieved in breeding them.

Aborigines.—The policy of conciliation unremittingly pursued for the last forty years has now secured a friendly reception for shipwrecked crews at any port of the islands except the south and west of Little Andaman and North Sentinel Island. The population is not susceptible of census, but probably it has always been small. Local expert guesses do not now place it higher than from 2500 to 3500, and though it is commonly asserted that the natives are going down before superior civilization, it is doubtful whether, except in the immediate neighbourhood of the penal settlement, there is as yet any permanent change in their numbers. Though all descended from one stock, there are ten distinct tribes of the Andamanese, each with its own clearly defined locality, its own distinct variety of the one fundamental language, and to a certain extent its own separate habits. Every tribe is divided into septs fairly well defined. The tribal feeling may be expressed as friendly within the tribe, courteous to other Andamanese if known, hostile to every stranger, Andamanese or other. Another division of the natives is into *Aryauto* or long-shore-men, and the *Eremtuga* or jungle-dwellers. The habits and capacities of these two differ, owing to surroundings, irrespectively of tribe. Yet again the Andamanese can be grouped according to certain salient characteristics: the forms of the bows and arrows, of the canoes, of ornaments and utensils, of tattooing, and of language. The average height of males is 4 ft. 10½ in.; of females, 4 ft. 6 in. Being accustomed to gratify every sensation as it arises, they endure thirst, hunger, want of sleep, and bodily discomfort badly. The skin varies in colour from an intense sheeny black to a reddish-brown on the collar-bones, cheeks, and other parts of the body. The hair varies from a sooty black to dark and light brown and red. It grows in small rings, which give it the appearance of growing in tufts, though it is really closely and evenly distributed over the whole scalp. The figures of the men are muscular and well-formed, and generally pleasing; a straight, well-formed nose and jaw are by no means rare, and the young men are often distinctly good-looking. The only artificial deformity is a depression of the skull, chiefly among one of the southern tribes, caused by the pressure of a strap used for carrying loads. The pleasing appearance natural to the men is not a characteristic of the women, who early have a tendency to stoutness and ugliness of figure, and sometimes to pronounced prognathism. They are, however, always bright and merry, are under no special social restrictions, and have considerable influence. The women's heads are shaved entirely, and the men's into fantastic patterns. Yellow and red ochre mixed with grease are coarsely smeared over the bodies, grey in coarse patterns, and white in fine patterns resembling tattoo marks. Tattooing is of two distinct varieties. In the south the body is slightly cut by women with small flakes of glass or quartz in zigzag or lineal patterns downwards. In the north it is deeply cut by men with pig-arrows in lines across the body. The male matures when about fifteen years of age, marries when about twenty-six, begins to age when about forty, and lives on to sixty or sixty-five

if he reaches old age. Except as to the marrying age, these figures fairly apply to women. Before marriage free intercourse between the sexes is the rule, though certain conventional precautions are taken to prevent it. Marriages rarely produce more than three children, and often none at all. Divorce is rare, unfaithfulness after marriage not common, and incest unknown. By preference the Andamanese are exogamous as regards sept and endogamous as regards tribe. The children are possessed of a bright intelligence, which, however, soon reaches its climax, and the adult may be compared in this respect with the civilized child of ten or twelve. The Andamanese are, indeed, bright and merry companions, busy in their own pursuits, keen sportsmen, naturally independent, and not lustful, but when angered, cruel, jealous, treacherous, and vindictive, and always unstable—in fact, a people to like but not to trust. There is no idea of government, but in each sept there is a head, who has attained that position by degrees on account of some tacitly admitted superiority and commands a limited respect and some obedience. The young are deferential to their elders. Offences are punished by the aggrieved party. Property is communal, and theft is only recognized as to things of absolute necessity, such as arrows, pig's flesh, and fire. Fire is the one thing they are really careful about, not knowing how to renew it. A very rude barter exists between tribes of the same group in regard to articles not locally obtainable. The religion consists of fear of the spirits of the wood, the sea, disease, and ancestors, and of avoidance of acts traditionally displeasing to them. There is neither worship nor propitiation. An anthropomorphic deity, Puluga, is the cause of all things, but it is not necessary to propitiate him. There is a vague idea that the "soul" will go somewhere after death, but there is no heaven nor hell, nor idea of a corporeal resurrection. There is much faith in dreams, and in the utterances of certain "wise men," who practise an embryonic magic and witchcraft. The great amusement of the Andamanese is a formal night dance, but they are also fond of simple games. The bows differ altogether with each group, but the same two kinds of arrows are in general use: (1) long and ordinary for fishing and other purposes; (2) short with a detachable head fastened to the shaft by a thong, which quickly brings pigs up short when shot in the thick jungle. Bark provides material for string, while baskets and mats are neatly and stoutly made from canes, and buckets out of bamboo and wood. None of the tribes ever ventures out of sight of land, and they have no idea of steering by sun or stars. Their canoes are simply hollowed out of trunks with the adze and in no other way, and it is the smaller ones which are outriggered; they do not last long and are not good sea boats, and the story of raids on Car Nicobar, out of sight across a stormy and sea-rippled channel, must be discredited. Honour is shown to an adult when he dies, by wrapping him in a cloth and placing him on a platform in a tree instead of burying him. At such a time the encampment is deserted for three months. The Andaman languages are extremely interesting from the philological standpoint. They are agglutinative in nature, show hardly any signs of syntactical growth, though every indication of long etymological growth, give expression to only the most direct and the simplest thought, and are purely colloquial and wanting in the modifications always necessary for communication by writing. The sense is largely eked out by manner and action. *Mincopie* is the first word in Colebrooke's vocabulary for "Andaman Island, or native country," and the term has thus become a persistent book-name for the people. It, or something like it, was probably one of the tribal names when Colebrooke wrote 120 years ago, and may be used

now, but this cannot be ascertained. Attempts to civilize the Andamanese have met with little success either among adults or children. The home established near Port Blair is used as a sort of free asylum which the native visits according to his pleasure. The policy of the government is to leave the Andamanese alone, while doing what is possible to ameliorate their condition.

Penal Settlement.—The point of enduring interest as regards the Andamans is the penal system, the object of which is to turn the life-sentence and few long-sentence convicts, who alone are sent to the settlement, into honest, self-respecting men and women, by leading them along a continuous course of practice in self-help and self-restraint, and by offering them every inducement to take advantage of that practice. After ten years' graduated labour the convict is given a ticket-of-leave and becomes self-supporting. He can farm, keep cattle, and marry or send for his family, but he cannot leave the settlement or be idle. With approved conduct, however, he may be absolutely released after twenty to twenty-five years in the settlement; and throughout that time, though possessing no civil rights, a quasi-judicial procedure controls all punishments inflicted upon him, and he is as secure of obtaining justice as if free. There is an unlimited variety of work for the labouring convicts, and some of the establishments are on a large scale. The general and marine steam and hand workshops employ 574 men; 72,000 burnt bricks are turned out daily during the season; in building the Cellular Jail some 30,000,000 bricks were used. Very few experts are employed in supervision; practically everything is directed by the officials, who themselves have first to learn each trade. Under the Chief Commissioner, who is the supreme head of the settlement, are a deputy and a staff of assistant superintendents and overseers, almost all Europeans, and sub-overseers, who are natives of India. All the petty supervising establishments are composed of convicts. The garrison consists of 140 British and 300 Indian troops, with a few local European volunteers. The police are organized as a military battalion 643 strong. The number of convicts has somewhat diminished of late years, and in 1900 stood at something over 11,000. The total population of the settlement, consisting of convicts, their guards, the supervising, clerical, and departmental staff, with the families of the latter, also a certain number of ex-convicts and trading settlers and their families, numbers about 13,000 males and 2000 females. The labouring convicts are distributed among four jails and nineteen stations; the self-supporters in thirty-eight villages. The elementary education of the convicts' children is compulsory. There are four hospitals, each under a resident medical officer, under the general supervision of a senior officer of the Indian Medical Service, and medical aid is given free to the whole population. The harbour of Port Blair is well supplied with buoys and harbour lights, and is crossed by ferries at fixed intervals, while there are several launches for hauling local traffic. On Ross Island there is a lighthouse visible for nineteen miles. A complete system of signalling by night and day on the Morse system is worked by the police. Local posts are frequent, but there is no telegraph, and the mails are irregular. A system of wireless telegraphic communication with India is in contemplation. In 1898 there were among the convicts 36 Christians, 2752 Mahomedans, 6585 Hindus, 1758 Buddhists, and 70 others. The convict death-rate was 25 per 1000, and 173 were set free after twenty to twenty-five years' average transportation. 265 children attended the school. Of 88 applications for permission to marry, 47 were granted. The total receipts (actual cash from timber, &c., apart from the value of the convict labour as such) in 1898 amounted to £36,359, as compared with only £27,826 in 1894, but with £50,421 in 1897. Expenditure, on the other hand, in 1898 amounted to £103,861, as compared with only £93,963 in 1894, but with £112,170 in 1897. Thus the net cost to Government in 1898 was £67,502; and the net annual cost per convict, £6·1. The variation in the amounts for different years is largely due to the fact that the forest year does not coincide with the revenue year, and to the great distance from London, whence payments are made.

AUTHORITIES.—Since 1875 there has been extensive research into the Andamanese and their country. The following books will be found to contain most of the necessary references.—*M.A.N. Aboriginal Inhabitants of the Andaman Islands.* London, 1883.—*PORTMAN. History of our Relations with the Andamanese.* Calcutta, Government, 1899; *Notes on the Languages of the South Andaman Group of Tribes.* Calcutta, Government, 1898; and *Record of the Andamanese.* xi. vols. MS. India Office, London, and Home Department, Calcutta.—*DE FOLIN. Mollusques des Îles Andamans.* Bordeaux, 1879.—*TEMPLE. Commercial Value of Wireless Telegraphic Communication with the Andaman and Nicobar Islands.* Calcutta, 1899. (R. C. T.)

Anderlecht, a town of Belgium, in the province of Brabant, 3 miles W. of Brussels, with numerous manufactures. It was formerly a part of Brussels, but was erected into a separate commune in 1895. Population (communal) (1897), 41,862.

Andersen, Hans Christian (1805-1875), Danish poet and fabulist, born at Odense, in Funen, on the 2nd of April 1805. He was the son of a sickly young shoemaker of twenty-two, and his still younger wife: the whole family lived and slept in one little room. Andersen very early showed signs of imaginative temperament, which was fostered by the indulgence and superstition of his parents. In 1816 the shoemaker died, and the child was left entirely to his own devices. He ceased to go to school; he built himself a little toy-theatre, and sat at home making clothes for his puppets, and reading all the plays that he could borrow; among them were those of Holberg and Shakespeare. At Easter 1819 he was confirmed at the church of St Kund, Odense, and began to turn his thoughts to the future. It was thought that he was best fitted to be a tailor; but as nothing was settled, and as Andersen wished to be an opera-singer, he took matters into his own hand, and started for Copenhagen in September 1819. There he was taken for a lunatic, snubbed at the theatres, and nearly reduced to starvation, but he was befriended by the musicians Weyse and Siboni, and afterwards by the poet Guldberg. His voice failed, but he was admitted as a dancing pupil at the Royal Theatre. He grew idle, and lost the favour of Guldberg, but a new patron appeared in the person of Jonas Collin, the director of the Royal Theatre, who became Andersen's life-long friend. King Frederick VI. was interested in the strange boy, and sent him for some years, free of charge, to the great grammar-school at Slagelse. Before he started for school he published his first volume, *The Ghost at Palnatøke's Grave*, 1822. Andersen, a very backward and unwilling pupil, actually remained at Slagelse and at another school in Elsinore until 1827; these years, he says, were the darkest and bitterest in his life. Collin at length consented to consider him educated, and Andersen came to Copenhagen. In 1829 he made a considerable success with a fantastic volume entitled *A Journey on Foot from Holman's Canal to the East Point of Amager*, and he published in the same season a farce and a book of poems. He thus suddenly came into request at the moment when his friends had decided that no good thing would ever come out of his early eccentricity and vivacity. He made little further progress, however, until 1833, when he received a small travelling stipend from the king, and made the first of his long European journeys. At Le Locle, in the Jura, he wrote *Agnate and the Mermaid*; and in October 1834 he arrived in Rome. Early in 1835 Andersen's novel, *The Improvisatore*, appeared, and achieved a real success; the poet's troubles were at an end at last. In the same year, 1835, the earliest instalment of Andersen's immortal *Fairy Tales* (*Eventyr*) was published in Copenhagen. Other parts, completing the first volume, appeared in 1836 and 1837. The value of these stories was not at first perceived, and they sold slowly. Andersen was more successful for the time being with a novel, *O. T.*, and a volume of sketches, *In Sweden*; in 1837 he produced the best of his romances, *Only a Fiddler*. He now turned his attention, with but ephemeral success, to the theatre, but was recalled to his true genius in the charming miscellanies of 1840 and 1842, the *Picture-Book without Pictures*, and *A Poet's Bazaar*. Meanwhile the fame of his *Fairy Tales* had been steadily rising; a second series began in 1838, a third in 1845. Andersen was now celebrated throughout Europe, although in Denmark itself there was still some resistance to his pretensions. In June 1847 he paid his

first visit to England, and enjoyed a triumphal social success; when he left, Charles Dickens saw him off from Ramsgate Pier. After this Andersen continued to publish much; he still desired to excel as a novelist and a dramatist, which he could not do, and he still disdained the enchanting *Fairy Tales*, in the composition of which his unique genius lay. Nevertheless he continued to write them, and in 1847 and 1848 two fresh volumes appeared. After a long silence Andersen published in 1857 another romance, *To be or not to be*. In 1863, after a very interesting journey, he issued one of the best of his travel-books, *In Spain*. His *Fairy Tales* continued to appear, in instalments, until 1872, when, at Christmas, the last stories were published. In the spring of that year Andersen had an awkward accident, falling out of bed and severely hurting himself. He was never again quite well, but he lived till the 4th of August, 1875, when he died very peacefully in the house called Røglighed, near Copenhagen. (E. G.)

Anderson, the capital of Madison county, Indiana, U.S.A., situated on the west fork of White river; a manufacturing city, at the intersection of three railways. Population (1900), 20,178.

Anderson, the capital of Anderson county, South Carolina, U.S.A., situated in the western part of the state, and surrounded by a fertile region, largely devoted to the production of cotton, of which this is a shipping point. It has three railways. Population (1900), 5498.

Anderson, Elizabeth Garrett (1836—), English medical practitioner, daughter of Newson Garrett, of Aldeburgh, Suffolk, was born in 1836, and educated at home and at a private school. In 1860 she resolved to study medicine, an unheard-of thing for a woman in those days, and one which was regarded by old-fashioned people as almost indecent. Miss Garrett managed to obtain some more or less irregular instruction at the Middlesex Hospital, London, but was refused admission as a full student both there and at many other schools to which she applied. Finally she studied anatomy privately at the London Hospital, and with some of the professors at St Andrews University, and at the Edinburgh Extra-Mural School. She had no less difficulty in gaining a qualifying diploma to practise medicine. London University, the Royal Colleges of Physicians and Surgeons, and many other examining bodies, refused to admit her to their examinations; but in the end the Society of Apothecaries, London, allowed her to enter for the License of Apothecaries' Hall, which she obtained in 1865. In 1866 she was appointed general medical attendant to St Mary's Dispensary, a London institution started to enable poor women to obtain medical help from qualified practitioners of their own sex. The dispensary soon developed into the New Hospital for Women, and there she worked for over twenty years. In 1870 she obtained the Paris degree of M.D. The same year she was elected to the first London School Board, at the head of the poll for Marylebone, and was also made one of the visiting physicians of the East London Hospital for Children; but the duties of these two positions she found to be incompatible with her principal work, and she soon resigned them. In 1871 she married Mr. J. G. S. Anderson, a shipowner, but did not give up practice. She worked steadily at the development of the New Hospital and (from 1874) at the creation of a complete School of Medicine in London for women. Both institutions have since been handsomely and suitably housed and equipped, the New Hospital (in the Euston Road) being worked entirely by medical women, and the School (in Hunter Street, W.C.) having over 200 students, most of them preparing for the medical degree of London University,

which was opened to women in 1877. In 1897 Mrs Garrett Anderson was elected president of the East Anglian branch of the British Medical Association. The movement for the admission of women to the medical profession, of which she was the indefatigable pioneer in England, has extended not only to every part of the United Kingdom and the British Colonies, but to every European country except Spain and Turkey.

Andersonville, a village of Sumter county, Georgia, U. S. A., on the Central of Georgia railway. During the Civil War it was the site of a Confederate prison for Federal soldiers. It is now the site of a national cemetery.

Andes.—The Andes form a continuous chain of mountainous highland along the western coast of South America, which, roughly speaking, may be regarded as 4400 miles long, 100 miles wide in some parts, and of an average height of 13,000 feet. The connexion of this system with that of the Rocky Mountains, which has been pointed out by many writers, has received much support from the discovery of the extensive eruptions of granite during Tertiary times, extending from the southern extremity of South America to Alaska. The Andean range is composed of two great principal chains with a deep intermediate depression, in which, and at the sides of the great chains, arise other chains of minor importance, the chief of which is that called the Cordillera de la Costa of Chile. This starts from the southern extremity of the continent, and runs in a northerly direction, parallel with the coast, being broken up at its commencement into a number of islands, and afterwards forming the western boundary of the great central valley of Chile. To the north this coastal chain continues in small ridges or isolated hills along the Pacific as far as Colombia, always leaving the same valley more or less visible to the west of the western great chain. These mountains were the objects of important investigations during the last quarter of the 19th century.

Of the two principal chains, the eastern is generally called Los Andes, and the western La Cordillera, in Colombia, Peru, and Bolivia, where it is likewise known as Cordillera Real de Los Andes, whilst to the south of parallel 23° S. lat. in Chile and Argentina, the western is called Cordillera de los Andes. The eastern disappears in the centre of Argentina, and it is therefore only the Cordillera de los Andes that is prolonged as far as the south-eastern extremity of the continent. The Cordillera de la Costa begins near Cape Horn, which is composed principally of crystalline rocks, and its heights are inconsiderable when compared with those of the true Cordillera of the Andes. The latter, as regards its main chain, is on the northern coast of Beagle Channel, in Tierra del Fuego, bounded on the north by the deep depression of Lake Fagnano and of Admiralty Sound. Staten Island appears to be the termination to the east. The Cordillera of the Andes in Tierra del Fuego is formed of crystalline schists, and culminates in the snow-capped peaks of Mount Darwin and Mount Sarmiento (7200 feet), which contains glaciers of greater extent than those of Mont Blanc. Sir Martin Conway recently ascended the latter. The extent of the glaciers is considerable in this region, which, geographically, is more complex than has hitherto been supposed. Although, in the explored portion of the Fuegian chain, the volcanoes which have been mentioned from time to time have not been met with, there seems to have existed to the south, on the islands, many neo-volcanic rocks, some of which appear to be contemporaneous with the basaltic sheet that covers a part of Eastern Patagonia. The insular region between Mount Sarmiento and the Cordillera de los Andes, properly so called, *i. e.*, that which extends from Magellan Strait northwards, has not been explored, and all that is known of it is that it is principally composed of the same rocks as the Fuegian section, and that the greater part of its upper valleys is occupied by glaciers that reach down to the sea amid dense forest.

As Admiralty Sound and Lake Fagnano, the extent of which is still unknown, bound the Cordillera to the north in Tierra del Fuego, so at the eastern side of the Cordillera in Patagonia there is

a longitudinal depression which separates the Andes from some independent ridges pertaining to a secondary parallel broken chain called pre-Cordillera. This depression is occupied in a great part by a series of lakes, some of these filling transversal breaches in the range, whilst others are remains of glacial reservoirs, bordered by morainic dams, extending as far as the eastern tableland and corresponding in these cases with transversal depressions which reach the Atlantic Ocean. Between the larger lakes, fed by the Andine glaciers of the eastern slope of the Southern Andes, are Lakes Maravilla, 100 square miles, and Sarmiento, 26 square miles, 51° S. lat., which overflow into Last Hope Inlet; Argentino, 570 square miles, 50° S. lat.; and Viedma, 450 square miles, 49° 30' S. lat., which empty into the river Santa Cruz; the fiordian Lake San Martin, 49° S. lat.; and Lakes Nansen, 18 square miles; Azara, 8 square miles; and Belgrano, 18 square miles, which are dependants of Lake San Martin (380 square miles), and Lakes Pueyrredon (98 square miles) and Buenos Aires (700 square miles), and which now overflow into the Pacific, through one of the remarkable inlets that are found throughout the Cordillera, the Calen Inlet, which is the largest western fiord of Patagonia. To the north of Lake Buenos Aires there is Lake Elizalde, which, while situated on the eastern slope, sends its waters to the Pacific Ocean, and Lakes Fontana (30 square miles) and La Plata (34 square miles), 45° S. lat., which feed the river Senguerr, which flows to the Atlantic. Lake General Paz (66 square miles), on the eastern slope of the Andes, at 44° S. lat., is the principal source of the Palena river, which cuts all the Cordillera, while Lakes Fetalanquen (20 square miles), Menendez (28 square miles), Rivadavia (10 square miles), and other smaller lakes, also situated between 43° 30' and 42° 30' S. lat. on the eastern slope, send their waters to the Pacific by the river Fetalenfu, which cuts through the Andes by a narrow gorge. The waters of Lake Puelo (18 square miles) likewise flow into the same ocean through the river of that name, which also cuts the Cordillera, and of which the principal affluent likewise drains the waters of a system of small lakes, the largest of which, Lake Mascardi, measures 17 square miles, which in comparatively recent times formed part of the basin of Lake Nahuel-Huapi (207 square miles), 41° S. lat. An extensive area of glacial deposits shows that a sheet of ice formerly covered the whole eastern slope to a great distance from the mountains. To the west another sheet reached at the same time the Pacific Ocean.

From the Strait of Magellan up to 52° S. lat., the western slope of the Cordillera does not, properly speaking, exist. Abrupt walls overlook the Pacific, and great longitudinal and transversal channels and fiords run right through the heart of the range, cutting it generally in a direction more or less oblique to its axis, the result of movements of the earth's crust.

The mountains forming the Cordillera between Magellan Strait and 41° S. lat. are higher than those previously mentioned in Tierra del Fuego. Generally composed of granite, gneiss, and Palæozoic rocks, covered in many parts by rugged masses of volcanic origin, their general height is not less than 6500 feet, while Mount Geikie is 7500 feet and Mount Stokes 7100 feet high. To the north are Mounts Mayo, 7600 feet; Agassiz, 10,600 feet; and Fitz Roy, in 49° S. lat., 11,120 feet high. The section from 52° to 48° S. lat. is a continuous ice-capped mountain range, and some of the glaciers extend from the eastern lakes to the western channels, where they reach the sea-level. The level of the lakes commences at 130 feet at Lake Maravilla and gradually ascends to near 700 feet at Lake San Martin. Passing the breach through which Lake San Martin empties itself into Calen Inlet, in 48° S. lat., is found a wide oblique opening in the range, through which flows the river Las Heras, fed by Lake Pueyrredon, which is only 410 feet above the sea-level to the east of the Andes, while Lake Buenos Aires, immediately to the north, is 710 feet. The Andes continue to be to the west an enormous rugged mass of ice and snow of an average height of 9000 feet, sending glaciers to all the eastern fiords.

Mount San Lorenzo, detached from the main chain in the pre-Cordillera, is 11,800 feet high. Mount San Valentin, 12,700 feet, is the culminating point of the Andes in the region extending from 49° to 46° S. lat., where another breach occurs, that of the river Huemules, which is supposed to be the outlet of Lake Elizalde to the east, and is followed by that of the river Aysen. These two breaches have emptied a large system of lakes, which, in pre-Glacial times, occupied the eastern zone, thus forming a region suitable for colonization in the broad valleys and hollows, where the rivers, as is the case with those in the north, cut through the Andes by narrow gaps, forming cataracts and rapids between the snowy peaks. Volcanic action is still going on in these latitudes, as the glaciers are at times covered by ashes, but the predominant rocks to the east are the Tertiary granite, while to the west gneiss, older granite, and Palæozoic rocks prevail. The highest peaks, however, seem to be of volcanic origin. Farther north, up to 41° S. lat., the water gaps are situated at a lesser distance one from the other, owing mainly to

more continuous erosion, this section of the continent being the region of the maximum rainfall on the western coast to the south of the equator. Between the gaps of the river Aysen and river Cisnes or Frias, which also pierces the chain, is found a huge mountain mass, in which is situated Mount La Torre, 7150 feet. These form the continental watershed, but in this region erosion is taking place so rapidly that the day is not far distant when Lakes La Plata and Fontana, situated to the east at a height of 3000 feet, and now tributaries of the Atlantic, may become tributaries of the Pacific. Already filtrations from the former go to feed western affluents through the granitic masses. To the north of Mount La Torre flows in the river Cisnes, 44° 48' S. lat., across another water gap, continuing the range to the north with high peaks, as Alto Nevado, 7350 feet, and Cacique, 7000 feet. The glaciers reach almost the western channels, as is the case at river Quelal. The northern glaciers, descending nearly to sea-level, are situated at 43° 40' S. lat. To the north of 45° S. lat. a well-defined western longitudinal valley, at some recent time occupied by lakes and rivers, divides the Cordillera into two chains, the eastern being the main chain, to which belong Mounts Alto Nevado, Cacique, Dentista, Maldonado, Serrano, each over 7000 feet high; Torrecillas, 7400 feet; Ventisquero, 7500 feet; and Tronador, 11,180 feet; while the western chain, broken into imposing blocks, contains several high volcanic peaks such as Mounts Tanteles, Corcovado, Minchimahuida, Hornopiren, and Yates. The rivers Palena, with its two branches, Pico and Carrenleufu, Fetaleufu, Puelo, and Manso, cut the two chains, while the rivers Refihue, Bodadahue, and Cochamo have their sources in the main eastern ridge. Mention has been made of active volcanoes in 51°, 49°, and 47° S. lat., but these have not been properly located. The active volcanoes south of 41°, concerning which no doubt exists, are the Huequen, in 43° lat., and the Calbuco, both of which have been in eruption during recent years.

The surroundings of Mount Tronador, consisting of Tertiary granite and basalt, form one of the most interesting regions in the Patagonian Andes for the mountaineers of the future. To the east extends the large and picturesque lake of Nahuel-Huapi, to the west is Lake Todos Los Santos (50 square miles), to which the access is easy and of which the scenery is of surpassing beauty. Between 41° and 38° S. lat., among other smaller lakes, are Lakes Traftul (45 square miles), Lacar (32 square miles), which, properly belonging to the system of Atlantic lakes, empties itself by the only water gap that occurs in this zone of the Cordillera into the river Valdivia, a tributary of the Pacific, Lake Lolog (15 square miles), Huechu-lafquen (45 square miles), and Lake Alumine (21 square miles). The volcanoes of Lanin, 12,140 feet; Quetopillan, 9180 feet; Villarica, 10,400 feet; Yaimas and Tolhuaca are all more or less active; the first is in the main chain, while the others are on the western slope. The scenery in the neighbourhood is magnificent, the snowy cones rising from amidst woods of arcanaria, and being surrounded by blue lakes. While the scenery of the western slope of the Andes is exceedingly grand, with its deep fiords, glaciers, and woods, yet the severity of its climate detracts considerably from its charm. The climate of the eastern slope, however, is milder, the landscapes are magnificent, with wooded valleys and beautiful lakes. The valleys are already partly settled by colonists. Between 52° and 40° S. lat. the erosion (fractures of the earth's crust) has carried the watershed of the continent from the summit of the Cordillera to the eastern plains of Patagonia.

Between 38° and 33° S. lat. the Andes have been somewhat extensively explored during the last ten years by the Argentine and Chilean Boundary Commissions. The highest peaks are volcanic, and their eruptions have sensibly modified the character of the primitive ridges. Outflows of lava and tufa cover the mountain sides and fill up the valleys. The Jurassic and Cretaceous formations, which, in the Southern Cordillera are situated outside of the range to the east, form to a considerable extent the mass of the great range, together with porphyric quartz, the Tertiary, granite, and other eruptive rocks, which have been observed along all the chain in South America up to Alaska in the north. Gneiss is seldom met with, but there are crystalline rocks, belonging chiefly to the pre-Cordillera of the eastern, and

to the Cordillera de la Costa on the western side. Silurian, Devonian, and Carboniferous rocks contribute to the formation of the pre-Cordillera, between 30° and 33° S. lat.

Whilst the axis of the Cordillera de los Andes from the south as far as 38° S. lat. is crystalline, to the north of this latitude the geological features change. At this point the range takes a vast transversal development, dividing itself into three separate groups, the easternmost being composed of Jurassic-Cretaceous beds, the central of Mesozoic layers and old eruptive rocks, the western of Tertiary granitic formation, with neo-volcanic lavas and active volcanoes on its western border. From the volcano of Copahue (height 9787 feet) the Andes take a great transversal extension; there are no wide intermediate valleys between the different ridges, but the main ridge is perfectly defined. Volcanic cones continue to predominate, the old crystalline rocks almost disappear, while the Mesozoic rocks are most common.

The higher peaks are in the main chain, whilst the Domuyo (15,317 feet) belongs to a lateral eastern ridge. The principal peaks between this and Mount Tupungato at 33° S. lat. are: Mount Cochico, 8255 feet; Campanario, 13,140 feet; Peteroa, 13,297 feet; Tinguiririca, Castillo, 16,535 feet; Volcano Maipu, 17,576 feet; Alvarado, 14,600 feet; Amarillo, 15,321 feet; Volcano San Jose, 19,849 feet; Pluquenes, 17,815 feet; and Volcano Bravard, 19,619 feet.

North of Maipu volcano, ascended by Dr Gussfeldt in 1883, the Cordillera is composed of two very huge principal ridges which unite and terminate in the neighbourhood of Mount Tupungato. The valley between them is 9000 feet high; and in that part of the Cordillera are situated the highest passes south of 33° S. lat., one of which, the Piuquenes Pass, reaches 13,333 feet, whilst the easiest of transit and almost the lowest is that of Pichachen, 6505 feet, which is the most frequented during winter. Throughout these regions the passes are numerous and of easy access in summer, but in winter they are generally dangerous.

To judge by certain features of this section of the Andes, it would seem that down to modern times, there existed across these mountains very low passes, through which some representatives of the Pampean fauna, such as the Mastodon and Equus, reached Chile, the remains of which have been discovered in the central valley of that country. The Andean glaciers at that time spread themselves down to the plain at the foot of the two slopes which then contained vast lakes, and where now exist extensive moraines and large erratic boulders. Mount Tupungato reaches 22,329 feet, according to Argentine measurement. To the north of this mountain, situated at the watershed of the Andes, extends a lofty region comprising peaks such as Chimbote, 18,645 feet, and Mount Polleras, 20,266 feet. The Pircas Pass is situated at a height of 16,962 feet. The gaps of Bermejo and Iglesia, in the Uspallata road, the best known of all the passes between Argentina and Chile, are at 13,025 feet and 13,412 feet altitude respectively, while the nearest peaks, those of Juncal and Tolorsa, are 19,358 and 20,140 feet high. Mounts Tupungato, Aconcagua, 23,393 feet, ascended lately by Mr Fitzgerald, Mr Vines, and Sir Martin Conway, and Mercedario, 21,982 feet, are the highest peaks of the central Argentine-Chilian Andes. These three peaks are formed of eruptive rocks, surrounded by Jurassic beds which have undergone a thorough metamorphosis. While in the west of the Andes, from the latitude of Aconcagua, the central valley of Chile runs without any notable interruption to the south end of the continent, a valley which almost disappears to the north, leaving only some rare inflexions which are considered by the Chilean geographers and geologists to be a continuation of the same valley; to the east in Argentine there commenced a longitudinal valley perfectly characterized, which runs along the eastern foot of the Cordillera separating this from the pre-Cordillera, which is parallel to the Cordillera de la Costa of Chile. Between Aconcagua and Mercedario are the passes of Espinacito, 14,803 feet, and Los Patos or Valle Hermoso, 11,736 feet, chosen by the Argentine General San Martin, when he made his memorable passage across the chain during the War of Independence. North of Valle Hermoso the Andean ridges, while very high, are not abrupt, and the passes are more numerous than in the south; some of them descending 10,000 feet, but most of them carrying between 13,000 and 14,000 feet. Pass

SCHEME OF THE ANDES RANGE.

Quebrada Grande is 12,468 feet in altitude; Cencerro, 12,944 feet; Mercedario, 13,206 feet; Ojota, 14,304 feet; Pachon, 14,485 feet; while Gordito is 10,318 feet. Farther north the passes are higher. Barahona Pass is 15,092 feet; Ternera, 15,912 feet; San Lorenzo, 16,420 feet, while the peak of the volcano reaches 18,143 feet; Mount Olivares, 20,472 feet; Porongos, 19,488 feet; Tortolas, 20,121 feet; and Potro, 19,357 feet.

As far as 28° S. lat. the Cordillera de los Andes has been principally formed by two well-defined ridges, but to the north, recent volcanic action has greatly modified its orography. Only a single line of passes characterizes the main ridge, and amongst them are the passes of Ollita, 15,028 feet; Peñas Negras, 14,435 feet; Pircas Negras, 13,615 feet; La Gallina, 16,240 feet; Tres Quebradas, 15,535 feet; and Aguita, 15,485 feet. To the north of Mount Potro the peaks in the Cordillera are not very prominent as far as the great mass of Tres Quebradas, but here are to be met with some that may be considered as amongst the highest of the whole range. Mount Aguita is 20,600 feet, and the culminating peak of those of Tres Cruces reaches 22,658 feet. To the east of the eastern longitudinal valley, at 27° S. lat., commences a high volcanic plateau between the Cordillera and the southern prolongation of the Bolivian Cordillera Real, which contains lofty summits, such as Mount Veladero (20,998), Mount Bonete (21,980), Mount Reclus (20,670), Mount Pissis (22,146), Mount Ojo del Salado (21,653), and Incahuasi (21,719). To the north of Tres Cruces is a transversal depression in the Cordillera, which is considered to be the southern termination of the high plateau of the Puna de Atacama. The Cordillera of the Andes borders the Puna to the west, while the Bolivian Cordillera Real bounds it to the east. In that region the Cordillera of the Andes is of comparatively recent origin, being principally constituted by a line of high volcanoes, the chief summits being those of Juncal, Panteon de Aliste, Azufre or Listarria (18,636), Lullaillaco (21,720), Miñiques (19,357), Socompa (19,948), Licancaur (19,685), Viscachuelas (20,805), Tapaquicha (19,520), Oyahuá (19,242), Ancaquicha (20,275), Olca (19,159), Miño (20,112), Sililica (21,100), Perinacota (20,918), Sagama (22,339), Tacona (19,740), Misti (19,029); to the east closes in the intermediary high plateau which commences at 28° S. lat. in Argentina. The principal peaks of the Bolivian Andes and its prolongation from south to north, are Famatina, in the centre of Argentina (20,340 feet), Laguna Blanca (18,307), Diamante (18,045), Cachi (20,000), Granadas, Lipéz (19,680), Guadalupe (18,910), Chorolque (18,480), Cuzco (17,930), Enriaca (18,716), Junari (16,200), Michiga (17,410), Quimza-Cruz (18,280), Illimani (21,190), and Sorata (21,490), the last two of which were climbed by Sir Martin Conway.

While the western range of the Cordillera is principally formed by volcanic rocks, the eastern (to the east of the range is Cerro Potosi, 15,400 feet) Andes of Bolivia are chiefly composed of old crystalline rocks. Between the ranges in the high plateau north to 27° are numerous isolated volcanoes which have been in activity in recent times, such as Peinado (18,898 feet), San Pedro (18,701), Antoco (19,029), Antofalla (20,014), Rincon (17,881), Pastos Grandes (17,553), Zapaleri (17,553), Suniquira (19,258), Tahue (17,458); volcanoes which have been elevated from a lacustrine basin, which very recently occupied the whole extension, and the remains of which are in the south, the Laguna Verde, at 28°, and in the north Lake Titicaca. The discovery of great Pampean mammals in the Pleistocene beds of that region shows that this upheaval of the latter is very recent, for in the heart of the Cordillera, as well as on the west coast of Bolivia and Peru, there have been discovered, in very recent deposits, the remains of some mammals which cannot have crossed the high range as it now exists.

The two Cordilleras that formed the Andes to the north of 28° S. lat. are continued in Peru, with the same characteristics—the western, chiefly volcanic, while its basis is crystalline; and the eastern, composed of green mica slate, primitive clay-slate, and granite, the more important of the two, which is cut by many large rivers, affluents of the Amazon, and which abuts on Ecuador. The western, which reaches an altitude of about 10,000 feet, then ceases to exist as a continuous chain, there remaining only a short, high ridge, called by Whymper the "Pacific range of the equator," and between this ridge and the crystalline Andean axis, the "avenue of volcanoes," to use his words, arises amidst majestic scenery. Chimborazo, which is not in the main chain, reaches 20,517 feet, Cotopaxi (19,580 feet), Antisana (19,260 feet), Coyambo (19,200 feet), are in the eastern range, with many other peaks of over 16,000 feet, which still contain glaciers. Under the equator, Sangay, 17,380 feet, according to Wolff, appears to be the most active volcano in the world. Pichincha, 15,804 feet, and Cotocachi, 16,297 feet, are the loftiest volcanoes of the western range. The Colombian Andes have recently been the subject of careful exploration. The three principal chains are continuations of those under the equator, but show very slight traces of volcanic action. In the western chain, which is remarkable for its regularity, the highest peak is

11,150 feet, and the lowest pass 6725 feet. The longitudinal valley of Canca forms the middle depression. The two chains appear to unite in the mountains of Antioquia. The eastern chain, separated from the central chain by the Magdalena depression, beginning north of the equator at 6000 feet, gradually rises to the height of Nevado, 14,146 feet, Pan de Azúcar, 12,140 feet, and in the Sierra Nevada de Cochi attains to peaks of 16,700 feet. The predominant rocks are gneiss, crystalline slate, and granite, and some Cretaceous and Tertiary shales. The central chain is unbroken, and is the more important of the two, owing to its greater altitudes, and is of volcanic character. To the south, near the equator, are Mounts Arapul, 13,360 feet, and Chumbul, 15,720 feet. The volcanoes Campainero, 12,470 feet, and Pasto, 14,000 feet, are also in that zone. Farther north is the volcano Purace, which presents a height of 16,000 feet; then come Huila, 18,000 feet; Santa Catalina, 16,170 feet; and Tolima, 18,400 feet; Santa Isabel, 16,760 feet; Ruiz, 17,390 feet; and Hervás, 18,340 feet.

Andes, Los, a state of Venezuela, formerly bounded on the N. by the states of Zulia and Lara, on the S. and E. by the state of Zamora, and on the W. by Colombia and a portion of Zamora. It had an area of 14,719 square miles, and a population estimated at 365,000. This area was recently divided into two states, Los Andes and Trujillo.

Andijan, a district town of Russian Turkestan, province of Ferghana, terminus for a time of the Transcaspian and Turkestan railway, lying 73 miles E.N.E. of Kokand on the left bank of the upper Syr-daria; altitude 1510 feet. It was formerly the residence of the Khans of Kokand, and is described as one of the most pleasant cities of Ferghana, on account of its beautiful gardens and large park situated in the midst of the town. A canal derived from the Syr waters these gardens, as well as the fields round the town. The cotton-tree being much grown in the district, Andijan is a centre for the trade in raw cotton, and has moreover nearly twenty factories for cotton cleaning, and several important firms. Andijan merchants, with their goods, are met with all over Central Asia. Population (1897), 46,680.

Andorra, or ANDORRE, a small neutral, autonomous, semi-independent state, with an area of 191 square miles, situated chiefly on the peninsular side of the Pyrenean chain. Its population, according to some estimates in 1887, was between 6000 and 12,000, but no trustworthy census exists. Its six parishes are subdivided into fifty-two pueblos or hamlets. The Andorrans are fond of the chase and of fishing in their streams. The more well-to-do classes now talk French fluently, and get their children educated in France. During the coldest winter months their communications are much easier with Spain than through the snow-clad passes leading into the Ariège. The local industries are of the most primitive kind,

merely domestic, as in the Middle Ages. Lack of capital, of coal, and of good means of communication, prevents the inhabitants from making use of the iron and lead mines that abound in their mountains. They rear flocks of sheep, goats, cattle, and some pigs. The only roads are bridle-paths, and one municipal road by the Balire Valley, connecting Andorra with the highroad to Seo de Urgel and Tarruga. There is a scheme for extending a branch of the projected Noguera-Pallaresa railway to Seo de Urgel, close to Andorra. The climate is cold in general, and bitterly so in winter. There are some sheltered spots on the southern side of the Pyrenean chain, called Solanas, where the climate is milder, and there the soil is better cultivated, producing some fruit and agricultural products for a small export trade. Milk, butter, hams, skins, and wool are sent to France. The French *viguier* is taken from the French department of Ariège and appointed for life, but the *viguier* of the bishop must be an Andorran, holding office for three years and re-eligible. There are notaries and clerks, auditors for each parish elected by the heads of families, police agents and bailiffs, chosen and sworn in, like all the above officers, by the council general. The archives are mostly kept in the "house of the valley" in the capital, Andorra Vicilla, a struggling village of 600 inhabitants. This Government house has no merit beyond the fact that in it the council general meets and has a chapel, and in it the aldermen, *viguiers*, and judge of appeal administer justice and assemble for all purposes of administration. Two magistrates, styled *rahanadores*, are appointed by the council general to see that *viguiers* and judges preserve the customs and privileges of Andorra. The parishes have a permanent patrol of six armed men, besides the militia. Spain and the bishop of Urgel are very jealous of French encroachments, and claim to have a better right to annex the little state some day. In the meanwhile it continues to pay each of the "coprincipes" £40 a year, levied by a tax on pastures.

(A. E. H.)

Andover, a municipal borough and railway station, in the Andover parliamentary division of Hampshire, England, on the Anton, 12 miles N.W. by N. of Winchester. In 1889 a recreation ground was opened. In 1891 the waterworks were acquired by the corporation. Area of borough (a parish), 8662 acres; population (1881), 5653; (1891), 5852; (1901), 6000.

Andover, a town of Essex county in north-eastern Massachusetts, U.S.A., having an area of 33 square miles. It is situated on the south bank of the Merrimac, where the surface of the country is broken by small Glacial hills. The Theological Seminary here had in 1898 eight instructors and 41 students, and Phillips Academy had a faculty of twenty professors and was attended by over 400 students. Population (1880), 5169; (1890), 6142; (1900), 6813.

Andovoranto. See MADAGASCAR.

Andrassy, Julius, COUNT (1823-1890), Hungarian statesman, was born at Zemplin in the north-east of Hungary, 18th March 1823. His father, Count Charles (the representative of a family which had been settled in Hungary about 250 years), was a man of considerable literary and scientific attainments, and was therefore (as were all who cared for the prosperity of the country) a member of the national and Liberal opposition to the deadening government of the Austrian bureaucracy. Julius and his elder brother Emmanuel were therefore, from their earliest

years, brought up to believe in the excellence of political liberty, and they were enabled by travelling to become acquainted with countries which enjoyed the free exercise of those institutions which the Government of Metternich refused to Hungary. His political master was Count Szechenyi, who has been called the greatest of the Hungarians. The two brothers were elected in 1847 members of the Hungarian Diet; they joined the Opposition, which was led by Louis Batthyany, Deak, and Kossuth. Andrassy soon distinguished himself by his speeches; he was one of those who first claimed to use Magyar. He had a charm of manner and gallantry which would have made him a favourite anywhere, and completely won the hearts of the susceptible Hungarians. As the differences between the aristocratic party and Kossuth became serious, Andrassy was on the side of Kossuth; he supported him through all the stormy events of 1848, and he accepted the post of prefect of the county of Zemplin in order to carry out the internal reforms which the democratic party desired; he paid special attention to the organization of the militia. In the civil war of 1848 against the Croats he took part at the head of the corps he had organized, and was present at the battle of Schwechat, when the Hungarians crossed the frontier and attacked the imperial troops on Austrian soil. He continued his association with the Government of national independence, and in 1849, when the interference of Russia became imminent, he went on a mission to Constantinople to ask for the aid of the Turks. In this he failed, but the Sultan promised to protect Hungarian refugees, a promise which was honourably kept, and which the Hungarians have not forgotten. Andrassy escaped the fate of many of his colleagues by flying from the country, but he was condemned to death under martial law and hanged in effigy. He spent the next years of exile in France and England, and acquired a very thorough knowledge of the customs and institutions of these countries; like so many of his countrymen he was an excellent linguist. He was pardoned by the emperor in 1856; on his return to Hungary he joined the party of Deak, who claimed the independence of the country, but hoped to attain it by reconciliation with the house of Hapsburg, a policy which was bitterly opposed by Kossuth and his followers. He sat in the Diet of 1861, but refused to recognize it as a substitute for an independent parliament, and during the following years he was very active in gaining support to the principles of the Moderates. His opportunity came in 1866. He took a leading part in the negotiations which led to the establishment of the "Ausgleich"; he was greatly instrumental in winning the confidence of the emperor and empress, and is said to have suggested the peculiar form taken by the Common Parliament or "Delegations." Deak was offered the post of minister-president of Hungary under the new constitution, but refused to take office; he suggested the name of Andrassy, who, he said, had been "sent by Providence." There was no one who could rival Andrassy's claims to be the first national Hungarian minister. As an old revolutionary he could command the adhesion of his former companions in exile; his birth and his early connexions won for him the support of the Liberal aristocracy, and he had the confidence of the emperor. He held this office for over four years, and quickly made political liberty and constitutional Government a reality, introducing full freedom of the press and of public meetings, granting political freedom to the Jews, and establishing the national militia or Honved, in which he took great personal interest. He exercised considerable influence on the foreign policy of the empire, and helped to keep in check the anti-German influences at Vienna. In 1870 he threw his weight decisively on the side of a public

declaration of neutrality. In 1871 he was called to Vienna to use his influence in order to prevent the emperor accepting the federalistic scheme of Hohenwart. Andrassy represented that it would destroy the organization of the dual monarchy, and offered his resignation if it was carried out. The result of the crisis was that Hohenwart was dismissed, and Andrassy received the portfolio for foreign affairs for Austria-Hungary after the fall of Beust. The most important achievement of his policy in the new post was the establishment of a close understanding with Germany. The beginnings of this had been laid by the friendly relations which Bismarck had already established with the Hungarians. This led also to a better understanding with Russia, and Andrassy was much attacked in Hungary for his Russophile policy. He succeeded, however, in averting a war with Russia, which might easily have arisen out of the Balkan complications; by the "Andrassy Note" of 1876 he attempted to settle these by agreement with Russia. The summoning of a European congress to discuss the terms of peace imposed on Turkey by Russia was to a great extent owing to his initiative, and he brought it about that the administration of Bosnia and Herzegovina should be offered to Austria-Hungary. His policy in this was strongly attacked at home, both by the Hungarians and Germans, and the discontent was increased by the difficulties with which the occupation of the provinces was attended; he had failed to anticipate the opposition with which the Austrian troops were met. It was partly this discontent which led him in the summer of 1879 to offer his resignation, a step which has also been attributed to private reasons; he was, moreover, dissatisfied that he was unable to have some internal reforms carried in Hungary. It is probable that he did not expect his resignation to be accepted; or if it was, he undoubtedly hoped soon to return to office. His position as the first of living statesmen in the dual monarchy was so assured that he might well believe he was indispensable. His resignation was, however, accepted. Before he left office, he completed the work he had already begun by arranging with Bismarck a formal alliance of Germany and Austria-Hungary for mutual defence against Russia. By this he had placed the European position of his country on a secure basis. The best proof of the wisdom of his policy is that it has been continued by all his successors.

Andrassy lived till 1890; he was never again offered office; he could have forced his way back to power had he chosen to use his great popularity for this purpose; but, with a magnanimity which is not too common, when he spoke in the parliament it was to help and support his successors; his criticisms he reserved for private intercourse. He died 18th February 1890. Andrassy is undoubtedly one of the most interesting figures of recent history. It has often been said of him that he cared more for the appearance than the reality; he thought too much of outward effect. He had little patience for the details and routine of departmental work, and was intolerant of slowness and stupidity. He had, however, a quick power of seizing the essential factors in a situation; his mind was eminently sober and practical; he saved his country from the dangers into which it would have fallen had full freedom been given to the ideals of Kossuth and his followers, or to the anti-Russian passions which were so strong. He is identified with two great political achievements, the system of dualism and the alliance with Germany; both have justified themselves by the test of experience. More than this, it is largely due to his personal influence that from the beginning it was made apparent that in the partnership between Austria and Hungary the latter was the stronger member; and so long as he was foreign minister he secured

for the dual monarchy a position in European affairs which it had not had for many years.

(J. W. HE.)

Andrews, Thomas (1813-1885), Irish chemist and physicist, was born on 19th December 1813 at Belfast, where his father was a linen merchant. After attending the Belfast Academy and also the Academical Institution, he went to Glasgow to study chemistry under Professor Thomas Thomson, and thence migrated to Trinity College, Dublin, where he gained distinction in classics as well as in science. He next spent some time in Paris, in the laboratory of the famous chemist Dumas, and finally, having graduated as M.D. at Edinburgh in 1835, settled down to a successful medical practice in his native place. Ten years later he was appointed vice-president of the newly-established Queen's College, Belfast, and professor of chemistry, and these two offices he held till 1879, when failing health compelled his retirement. He died 26th November 1885. Andrews first became known as a scientific investigator by his work on the heat developed in chemical actions, the Royal Society awarding him a Royal medal in 1844. Another important research was devoted to proving that ozone is a definite body, an allotropic form of oxygen, containing three atoms in the molecule instead of two, as is the case with the ordinary gas. But the work on which his reputation mainly rests and which best displayed his skill and resourcefulness in experiment was concerned with the liquefaction of gases. He carried out a very complete inquiry into the laws expressing the relations of pressure, temperature, and volume in carbonic acid gas, in particular establishing the conceptions of critical temperature and critical pressure, and showing that the gas passes from the gaseous to the liquid state without any breach of continuity.

Angers, chief town of department Maine-et-Loire, France, and an important centre for several railway lines, 188 miles S.W. of Paris. There is a Hôtel-Dieu, now a civil and military hospital; but it is the Hôpital-Ste-Marie, a large modern building with 1500 beds, that takes the place of the ancient Hôtel-Dieu or Hospice St Jean, said to have been founded by Henry II., which is now occupied by the archæological museum. The public library, contained in a fine edifice dating from the 15th century, has been much enlarged. Palæontological and antiquarian museums are also housed in ancient buildings of considerable interest. A 12th-century clock tower is part of the ancient abbey of St Aubin. The Palais de Justice is a modern building in the Champ de Mars. Amongst educational institutions may be noted a national school of arts and handicrafts, a free school of design, and a school of pharmacy. Manufactures of umbrellas, boots and shoes, iron goods, cables, and copper ware, have become important. In the vicinity are many nursery gardens. Large stock fairs are held, and there is considerable trade in hemp, flax, and other agricultural produce. Electric tramways connect with the suburbs. Population (1881), 58,571; (1891), 62,391; (1896), 69,484, (comm.) 71,119.

Angiosperms.—The term "Angiosperm" (*ἀγγέιον*, receptacle, and *σπέρμα*, seed) was coined in the form Angiospermæ by Paul Hermann in 1690, as the name of that one of his primary divisions of the Plant Kingdom which included flowering plants possessing seeds enclosed in capsules, in contradistinction to his Gymnospermæ or flowering plants with achenial or schizocarpic fruits—the whole fruit or each of its pieces being here regarded as a seed and naked. The term and its antonym were maintained by Linnæus with the same sense, but with restricted application, in the names of the orders of his

class *Didymia*. Its use with any approach to its modern scope only became possible after Robert Brown had established, in 1825, the existence of truly naked seeds in the *Cycadeæ* and *Coniferæ* entitling them to be correctly called *Gymnosperms*. From that time onwards, so long as these *Gymnosperms* were, as was usual, reckoned as dicotyledonous flowering plants, the term *Angiosperm* was used antithetically by botanical writers, but with varying limitation, as a group-name for other dicotyledonous plants. The advent in 1851 of Hofmeister's brilliant discovery of the changes proceeding in the embryo-sac of flowering plants, and his determination of the correct relationships of these with the *Cryptogamia*, fixed the true position of *Gymnosperms* as a class distinct from *Dicotyledones*, and the term *Angiosperm* then gradually came to be accepted as the suitable designation for the whole of the flowering plants other than *Gymnosperms*, and as including therefore the classes of *Dicotyledones* and *Monocotyledones*. This is the sense in which the term is nowadays received and in which it is used here.

The *Angiosperms* and the *Gymnosperms* together compose the group of *Spermophytes*—also named *Phanerogams*—Seed Plants or Flowering Plants. The expressions seed plant and flowering plant convey the essential character of the group. The seed is the product of the flower—the conception of the flower implies that of the seed. In no other group of plants is there a seed or a flower, although the terms are sometimes loosely used with reference to plants of lower organization. The trend of the evolution of the plant kingdom has been in the direction of the establishment of a vegetation of fixed habit and adapted to the vicissitudes of a life on land, and the *Angiosperms* are the highest expression of this evolution and constitute the dominant vegetation of the earth's surface at the present epoch. There is no land-area from the poles to the equator, where plant-life is possible, upon which *Angiosperms* may not be found. They occur also abundantly in the shallows of rivers and fresh-water lakes, and in less number in salt lakes and in the sea; such aquatic *Angiosperms* are not, however, primitive forms, but are derived from immediate land-ancestors. The varying climatic or environmental

conditions to which *Angiosperms* may be exposed in their wide distribution, including those of the soil, *edaphic*, those of the atmosphere, *epedaphic*, and those of water, *aquatic*, find their response within the limits of phylogeny, in the external form and internal structure exhibited by the plants. *Angiosperms* of a tropical forest, for example, are manifestly of different form from those of an alpine region, or again *Angiosperms* growing submerged in a lake have features readily separating them from plants of a desert plain; the differences are not confined to points of their outward form, but obtain throughout their internal structure. The study of the relationships of *Angiosperms*, as well as of other plants, to their environment has in recent years become a fascinating and productive field of botanical work to which has been given the designation "*Öcology*" (sometimes written "*Ecology*"). From the standpoint of their relation to environment *Angiosperms* fall into the three main categories of *Geophytes*, *Aerophytes*, *Hydrophytes*. *Geophytes* are plants adapted to a land-life with fixation in the soil, and therefore they are subject to the influence of both *edaphic* and *epedaphic* factors of environment. *Aerophytes* are adapted to a land-life with fixation upon another plant, and are therefore subject to the influence of *epedaphic* factors of environment only. *Hydrophytes*, being adapted to life in water, whether free or fixed, are subject to the influence of the aquatic environment alone. These categories are not altogether

sharply distinguishable, and many plants have the capacity of dual adaptation; e.g., *Batrachian Ranunculi* may be either hydrophilous or geophilous; *Ficus bengalensis* as a juvenile is aerophilous, but geophilous when adult.

I. *Geophytes*.—*Geophytes* overwhelmingly predominate in the world, and from them we derive our concept of the typical *Angiosperm*, which for the performance of its life-work has two series of vegetative organs severally adapted to the media—soil and atmosphere—in which they are exposed. They are the root or descending system and the shoot or ascending system composed of stem and leaf. To the root belongs the special work of fixing the plant in the soil and of absorbing material for food in a liquid state. To the shoot is assigned the special task of taking in material for food in a gaseous form from the atmosphere and of absorbing the radiant energy of the sun.

Vegetative organization.

The primary root formed at the base of the embryo pierces the soil as a main radially-constructed orthotropous root, from which lateral endogenetic plagiotropous rootlets branching like the mother proceed. Roots elongate by means of an intercalary pluricellular growing point covered by a protecting root-cap, and bear over a short distance close behind the point a covering of short-lived active hairs, the agents alike of fixing and absorbing.

The depth to which the root-system of *Angiosperms* penetrates the soil is apparently conditioned by the needs of respiration, and even in plants with highest shoot-development in temperate regions is not over 4 feet, save in exceptional conditions. The growth in length of the main root is therefore soon arrested. The horizontal extension of the lateral roots is practically indefinite. The elongation and persistence of the primary root is a characteristic feature of dicotyledonous *Angiosperms*, and is in marked contrast with what is commonly found in *Monocotyledones* and in *Pteridophytes*, and is evidently correlated with their more elaborate development of shoot. Where the primary root elongates in *Monocotyledones* it rarely persists for any time, even in cases where there is a considerable bulk in the shoot-system; the root-system is then provided by adventitious roots from the stem.

The primary shoot-axis has two portions—the hypocotyl with its cotyledon or cotyledons, the portion first formed in the embryo, and the epicotyl, which in the embryo exists as the plumular bud. The latter elongates as a radial orthotropous axis, with a terminal pluricellular growing point of indefinite growth covered more or less by incipient leaves, both scale-leaves and foliage-leaves, to form a leaf-bud, and these arise from nodal points as exogenetic outgrowths, commonly dorsiventral and of limited intercalary basipetal growth. Branches like the parents, but plagiotropous and often dorsiventral, arise exogenetically in the axils of the leaves. The leaves (as also their axillary branch) have a definite position—spiral or cyclic—upon the stem.

The degree to which the shoot is developed and its duration above ground have given origin to the popular designations *herb*, *shrub*, *tree*, and these terms, although not capable of scientific definition, for the forms they indicate pass one into the other, are nevertheless landmarks in outward form development—*growth-forms*—in relation to climatic factors, and are therefore of *öcological* value. To them may be added *liane*, as the designation of a subsidiary form of widespread occurrence. A herb being a plant—annual or perennial—which loses and renews its shoot-growth from year to year, and often also loses and renews its root-system, does not rise to any great height above the soil. It is therefore not greatly exposed to air-currents, and it may for a considerable portion of the year be subterranean and consequently under more equable conditions than when above ground; it dwells in a moist stratum of the

Growth-forms.

atmosphere and may readily be overshadowed by other plants. Herbaceous growth makes a carpet of vegetation upon all areas of the earth's surface, but is essentially a feature of temperate regions. Trees, on the other hand, have a persistent aerial trunk with copious shoots, and they are therefore woody and may be evergreen or have deciduous leaves. Their growth brings them into atmospheric strata drier than those near the soil, where they are more exposed during the whole year to air currents and to every change of temperature, and where they are not liable to be overshadowed except by their fellows. Tree-growth then may be said to affect moist sheltered areas; cold dry wind-swept regions, for instance the polar and alpine, are treeless. As the intermediate form between herbs and trees the shrub merges into both, and is found along with or replacing them in all areas. The liane may partake of the character of each of the preceding forms, but its special feature is that rooting in the soil it makes use of the support of other plants to secure an extension and exposure in the atmosphere, and in this way may attain a length of many yards. To this end it may adopt the habit of a twining stem, or it may climb by means of modifications of its organs, such as prickles, hooks, leaf-tendrils of various degrees of conversion, and stem-tendrils of kinds. Liane-growth is found in all areas of vegetation, except, and for obvious reasons, in polar and alpine regions, but it reaches its maximum development in the tropics, where woody twining stems and stem-tendrils are specially developed.

A fundamental character of Angiosperms, as indeed it is of all plants excepting the unicellular Protophytes, but one which is too often lost sight of in the study of their economy, is their colonial organization. The living plurinucleated protoplasm of the plant-body is spread over the skeletal support furnished by the cells of the root and shoot, and in the more highly differentiated forms occupies but a small area of the whole body of the plant. Each living cell encloses an energid (a portion of the protoplasm dominated by a nucleus) which is connected by protoplasmic threads piercing the cell-membrane with the adjacent energids, and thus the protoplasmic body forms one continuous whole in the plant. (See CYTOLOGY.) According to their position in the organism, the primary cells become devoted to the formation of special tissues building up the organs required for the discharge of the several life-functions of the plant, but nevertheless each living cell must be regarded as a potential protophyte, whilst its actual destiny is determined by its relations to the other cells. This colonial organization of the Angiosperm enables it to have growth prolonged in one direction whilst this is arrested in another, to throw off effete and old parts of its body without mutilation, and to renew or replace them as required; all tissues which pass out of the sphere of active life are not, however, thrown off, for it is a marked feature of Angiosperms that such tissues, and many excreta also, may be enclosed by the living ones and remain unchanged so long as they are unexposed to the putrefactive influences of the atmosphere. The fixed organism as a whole is endowed with what we may term potential immortality—

Duration of life.

a character in sharp contrast with the relatively short period of life of the motile individuals of the higher members of the animal kingdom. We have but little accurate information bearing upon the actual longevity of Angiosperms by which to judge whether their theoretical expectation of life may come to realization. Perennating herbs and under shrubs probably approach most nearly to its fulfilment. Shrubs and trees expose themselves by their aerial growth to many accidents which militate against great length of life; nevertheless there are authentic instances of trees, for instance *Ficus religiosa*, whose

years must be counted by thousands. On the other hand many Angiosperms are pronouncedly short-lived, passing through birth, vegetation, reproduction, and death within a few months.

For an account of the internal organization of Angiosperms, see ANATOMY OF PLANTS. The primary disposition of the permanent tissues in an Angiosperm is determined by the necessity of providing an ample mechanism for carrying water from the absorbing ends of the roots to the other seat of absorption of food material in the leaves, and to all growing points for the maintenance of turgidity; the carrying system therefore dominates the anatomy, its position and form in each organ having relation to the strain to which the organ is liable. In Dicotyledones the monostelic system admits of an indefinite extension of the area of the carrying system to keep pace with the growth and extension of the often ample perennating shoot-system, and this has contributed largely to the establishment of the group as the dominant vegetation of our day. The polystelic condition so common in Pteridophytes is occasionally found, but only in forms which are not progressive. The absence of this capacity of increase of the carrying system in Monocotyledones is probably one of the factors which have led to their insignificant development as tree-forms as compared with Dicotyledones.

Though the geophyte responds in some degree in the configuration of its vegetative organs to all the physical and chemical conditions of its environment, we have as yet but little certain knowledge of the effect to be ascribed to some of these or of the manner of their operation. Nor are we able as

Environment and configuration.

yet, even in the case of those factors of which we know most, to determine clearly in every instance how far their influence is controlled by intrinsic causes, expressed for instance in correlation, or is modified in combined action with other factors. We know that the direction and disposition of the parts of the root and shoot are directly influenced by the stimulus of gravity, and also that radial and dorsiventral constructions are often conditioned by light which also may induce anisophylly and the flattening of organs; light also may be a direct cause in provoking a difference in form between the juvenile and adult foliage, with the result that the organs concerned in carbon-dioxide-assimilation and in the absorption of energy are exposed in the most favourable manner to illumination. The direct influence of light in formation of chlorophyll is well known. Configuration appears to be but little directly influenced by temperature excepting perhaps by extreme cold, and we can seldom say by consideration of its outside whether a plant inhabits a warm or a cold climate, notwithstanding the paramount influence temperature exerts in the distribution of specific forms. The most influential environmental factor in relation to form and structure is unquestionably water. Water-carriage within the plant determines its anatomy, and the safeguarding of the water-supply alike at its intake in the root-system and at its outgo by transpiration and by transudation in the shoot, is a prime concern of the vegetative organization of geophytes, and is modified in relation to the amount of water available for the functional purposes of the plant. This does not always correspond with the actual amount of water in the physical environment, and a plant may be in a condition of physiological drought in the midst of an abundance of water. When there is a risk of physiological drought—as in areas where the absorption of water from the soil is hindered, **Xerophily.** e.g., by a scant amount of water, by too much dissolved salt, by humus, or by low temperature, as well as where transpiration and transudation are facilitated, e.g., by the dryness or high temperature of the atmosphere, by low barometric pressure, and by intense light—the plant responds and means are developed to promote the intake and check the outgo. For the former there may be an increase of the whole root-system and of the absorbing

hairs, as well as of the carrying vasa; for the latter there is great variety of method in relation to other oecological factors. There may be a reduction in the amount of the transpiration-surface by the shortening and thickening of the stem and the foliage-leaves, or even by the suppression of the latter (*aphylly*) leading to stem-assimilation, the development of *cladodes*, and the production of non-transpiring *thorns*, while by the formation of vertical leaves and *phyllodes* the effect of insolation is restricted. Obstacles to transpiration are created by increase in thickness and in cutin-content of the outer wall of the epidermal cells, by the sinking of the stomata, by the development of a covering of hairs, or in compound leaves by collapsing movements. In many cases water-storage of kinds is provided, from which loss may be supplied and succulence of stem (*chylocaulis*) or of leaf (*chylophyllis*) is developed. An increase in the sclerenchyma-tissue of stem (*sclerocaulis*) or of leaf (*sclerophyllis*) and an elongation of the palisade-cells of the leaf are also accompaniments of this adaptation. Such adaptations are termed *xerophilous*, and plants exhibiting them are *Xerophytes*. The conditions which induce the xerophilous structure are conspicuously and most typically found in desert areas, but they also, in varying degree, surround plants growing on the surface of rocks (*Lithophytes*), in rock-fissures (*Chasmophytes*), on sandy porous ground (*Psammophytes*), on the shore (*Halophytes*), on peat-moors (*Ericophytes*), and elsewhere. In marked contrast with xerophilous configuration and structure are the *hygrophilous* features which characterize *Hygrophytes* or plants *Hygrophyly*. which are not, or only rarely and temporarily, liable to any danger from deficiency of water-supply. Here the presence of a feeble absorptive root-system and an extended surface of the shoot for transpiration and transudation are the outstanding points. The latter is exhibited in the elongated stems which do not bear thorns, although prickles are not uncommon, the large surface and the thinness of the leaves which frequently have "dropper tips" or other arrangements for quickly throwing off water, the large air canals, abundant and exposed stomata, and many hydathodes. The risk to hygrophytes lies in their exposure to strong insolation or to prolonged air currents, and these may cause flagging of the organs; but loss from such causes is soon recovered, and may be provided against by water-storage in or near the epidermis. Hygrophytes occur in moist areas, and are particularly abundant in the tropics. The degree to which xerophilous or hygrophilous construction is developed varies, and some plants exhibit a seasonal alternation of these characters, and *Tropophily*. have been therefore termed *Tropophytes*. In the wet or warm season they are hygrophilous, in the dry or cold season they are xerophilous. The feature distinguishing them is the casting of the greater portion of their transpiration-surface at the beginning of the period when there is a risk of physiological drought, by the dying down of the annual shoots of herbs, and by leaf-fall and branch-fall of shrubs and trees. That this is a preparation for physiological drought every gardener may see when he transplants such an evergreen as a holly. Deciduous-leaved trees and shrubs of temperate regions have hygrophilous foliage, but the stems are xerophilous, being protected by cork, and the buds are enveloped in scales, resin, and so forth. Evergreens of temperate regions have xerophilous leaves, their young leaves alone showing hygrophilous characters. Any one of the growth-forms—herb, shrub, tree, liane—may exhibit features of xerophily, hygrophyly, or tropophily, and their adaptations upon these lines determine the physiognomy of vegetation within the thermal zones of the globe.

Angiosperms (like Gymnosperms) are heterosporous, as

are some of the Pteridophytes, but unlike these they do not spread by the scattering of the megaspores. On the contrary the megasporangium remains persistently closed and attached to the sporiferous plant, whilst the megaspore which it contains (for there is commonly but one) germinates within it and produces the structures which are the homologues of the female gametophyte of the Pteridophytes with its female gametes. Nor does this intrasporal development cease here. Conjugation of the male and female gametes takes place within the spore, as does also the subsequent segmentation of the resulting zygote, and its further development through the stage of pro-embryo to the formation of the perfect embryo of a sporophyte. There is thus produced in the position of the original megasporangium a body consisting, in its simplest form, of a coat to the outside composed of the wall of the megasporangium and of the wall of the megaspore, both of them much altered, and within of an embryo sporophyte. This body is the *seed*. For a longer or shorter time it remains attached to the sporiferous plant, and its ultimate separation provides for the spread of the angiospermous plant. It is this character—of a closed megasporangium and the development of seed—which separates sharply the Angiosperms and the Gymnosperms from all other classes in the plant kingdom, and which makes so apt their designation in one group—the Spermophytes. The exigencies of their adaptation as a land-vegetation have made the development of sexual cells in them not a first charge upon an independent or nearly independent organism arising from a spore, as is the case in the Pteridophytes, but these appear as late products on a vast vegetative structure through which the outcome of their coalescence, the embryo, can be nourished for a time, and from which it is subsequently shed, well protected in the seed-coat to withstand climatic vicissitudes yet ready to take its position as a new plant whenever environmental conditions permit. The risk of failure of sexual reproduction through non-propinquity of the essential energids overhangs the higher Pteridophytes at two stages of their life history, and frequent actual failure may have hastened their retrogression as a dominant vegetative type; there is first of all that of non-association on the same nidus of the fortuitously distributed microspores and megaspores, and second that of a missing of coalescence of the male and female gametes, inasmuch as the act involves a sufficiency of moisture for germination, and through which the male gamete must actively move to its goal. In the Angiosperms this risk is, to their advantage, reduced to a single one, that of a mishap in pollination, for the avoidance of which have been developed the elaborate contrivances which make up the flower of to-day.

The part of the Angiosperm through which the formation of seed takes place is the flower. This is a shoot, bearing sporangia which contain spores, both sporangia and spores being concerned in the production of the seed. Function as well as structure is therefore involved in the conception of flower. Sporangiferous shoots resembling those of some Angiosperms are found outside the Spermophytes in, for example, *Selaginella*, and they have the structural features of flower, but they do not form seed, and are therefore not flower. Nowhere, except in the Gymnosperms and Angiosperms, do we find such sporangiferous shoots implicated in the physiological processes which result in the seed. The *microsporangia* (*pollen-sacs*) containing *microspores* (*pollen-grains*) and the *megasporangia* (*ovules*) containing *megaspores* (*embryo-sacs*) are enclosed in leaves, respectively, the *microsporophylls* (*stamens*) and the *megasporophylls* (*carpels*) attached to the *axis* (*torus*) of the flower.

**Gamo-
genetic
reproduc-
tion.**

**The
flower.**

These leaves may be together on the same torus (*hermaphrodite flower*), or on separate ones (*unisexual flower*). The stamen has typically a petiolar portion (*filament*), and a laminar portion (*anther*), and within the latter the pollen-sacs, of which there are commonly four, each containing many pollen-grains, are embedded. The carpel is a leaf folded upon itself to form an ovary investing the ovules. These arise, each with its embryo-sac, from the tissue of the placenta placed either upon the carpel (*foliar*) or upon the torus (*axial*) which projects into the cavity of the ovary; in epigynous flowers the torus shares more or less in the formation of the wall of the cavity. The apex of the carpel is more or less prolonged as the *style* upon which a special papillar or hairy secreting germinating surface of varying extent, the *stigma*, is developed. Upon this stigmatic surface the pollen-grains which are carried to it (*pollination*) from their mother pollen-sacs, continue their germination, and then through the pollen-tube the male gametes they produce are conveyed to the female gamete enclosed in the megaspore. The anther-wall enclosing the pollen-sacs is commonly no more than an epidermis in the greater part of its extent, and usually contains parasolar colouring substances which protect the developing pollen-grains. It forms with the walls of the pollen-sacs a hygroscopic mechanism, through which it is ruptured in definite areas for the escape of the pollen-grains at the period when these are mature. The ovarian wall is green, or possesses at least some chlorophyll and frequently meristem, and thereby is fitted for the subsequent developments through which it becomes the fruit, enclosing for a longer or shorter period the seeds into which the ovules develop. The number, form, size, colour, cohesion, adhesion, branching of the sporophylls give manifold variety of flower-structure, but the features in the sporophylls which are of significance from the phyletic standpoint, and by which the Angiosperms as a whole are distinguished from the Gymnosperms are—(1) the greater protection afforded to the ovules by their enclosure within the ovary of the carpel, and (in the higher forms) within the torus itself, and to the pollen-sacs by their investment in the anther; and (2) the provision of a carpellary germinating surface in the stigma for the pollen-grains, with the correlated specialization of the stamen into filament and anther.

The flower may be constituted by the sporangiferous portion alone, and the sporophylls are sometimes spoken of as its essential organs.

But the parts which give conspicuousness to most flowers, and which are indeed in the popular and gardening sense of the term "flower" the important ones, are the flower-envelopes—*calyx* of *sepals* and *corolla* of *petals*. One of these only may be present. Their presence is a mark of angiospermous structure, the flower in Gymnosperms having only obscure homologues. Sepals are typically green, and share therefore in the assimilation-work of the plant, no doubt aiding in meeting the very great demands made upon the plant-energy by spore-formation in the flower and its consequences. They are frequently persistent and active in this way during the whole period of maturation of the seed. Whilst in the earlier stages of the flower-development they serve as protecting structures to the parts within, they also when persistent provide a protection, or it may be an aid in dissemination, to the fruit or seed. The brilliant colours of the flower are most frequently located in the petals, although the sepals and sporophylls and adjacent parts are also often coloured. With the calyx the corolla serves as a protection to the young sporophylls, especially from wet. Once expanded the petals may remain so until they are shed, as they usually are after pollination has been effected, or they may with the calyx close over the sporophylls and open

again, more than once, in response to various external stimuli. Their colours, primarily parasolar, appear to be attractive to birds and insects, and these by their visits aid in the pollination of the flower, and have been agents in the intensification of the colours through selection. The leaves of the flower-envelopes vary in every way more than do the sporophylls, and show frequently extreme specialization in their forms, which in many cases appear to be correlated with the visits of birds and insects. Another accessory feature present in many flowers, and especially in those with colour, is the secretion of honey, with the associated odour, from nectaries. These nectaries, often termed *nuptial*, to distinguish them from similar ones which occur upon parts of the plant away from the flower (*extranuptial*), may arise upon the torus independently of the flower-leaves, or may be produced by any one of these leaves. The secretion is usually discharged from the nectaries, but in some cases is retained, and can only be secured by puncture. Odour appears to be the most potent attraction to birds and insects possessed by flowers.

The flower has primarily a radial construction with a spiral or cyclic (or these combined) disposition of the flower-leaves; the terminal flower of an inflorescence is always radial. Lateral flowers may be radial, but are frequently dorsiventral, a construction which, primarily an adaptation to physical needs, has been intensified by insect-agency. The relative number and positions of the different kinds of flower-leaves are characteristic features, and in lateral flowers have a definite relationship to the mother-axis of the flower, as well as to the prophylls—the common trimery of Monocotyledones showing typically an anterior sepal in relation to the one posterior prophyll, whilst in the pentamery and dimery of Dicotyledones there is usually a posterior sepal with a pair of lateral prophylls. All these relationships (and they are of great variety) of the flower-leaves are of considerable value in the estimation of the genetic relationships of the families of Angiosperms. The formation of flower concludes the growth in length of the axis to which it belongs. If this be the primary, or relatively primary axis the plant is *monaxial*; the majority of plants are, however, *pluriaxial*, the flowers belonging to axes of higher degree. In both cases there is a tendency to aggregation of the flowers in inflorescences, whereby small flowers become more conspicuous and the function of the flower is promoted. The position of the sporophylls at the end of their axis gives them prominence, and the whole arrangement of flower, whether solitary or in inflorescences, at the extremity of shoots, and its projection, as is common, beyond the vegetative organs, is of obvious advantage. In contrast with the usual relation, *cauliflorous* trees are not uncommon in the tropics. In them the flowers, which have often somewhat fleshy flower-envelopes, and are always odorous, appear singly or in groups upon small short-lived twigs, which develop from persistent axillary buds, or are found issuing from "latent eyes" in the bark. Their position close to the seat of reserve-food is evidently an economical one, and may have a relation to pollination, and their occurrence in tropical trees and absence from those of temperate regions may be made possible by the thinner bark developed upon trees in the tropics. The antagonism observable between vegetative and reproductive functions is well known, and environmental conditions such as physiological drought and low temperature, which are unfavourable to vegetative activity, are not so unfavourable to, and even favour, reproduction. Periodicity in flowering is most marked where there is seasonal growth, and flowering commonly concludes a vegetative period in which takes place an accumulation of energy sufficient to supply the demands made in the seed-formation, the exhausting nature of which is shown by the long intervals for recuperation, often a dozen years, between successive full crops in such trees as beech. When flower is produced before seasonal vegetative activity begins, a store of reserve-food from a preceding year is available for its formation. Where seasonal growth is not sharply marked, as in parts of the tropics, there may be continuance of flower during the whole year, but not from the same shoots. The action of light in intensifying the colour and odour of alpine flowers is well known.

The sporogenous tissue is formed within each of the four sporangia, two of which are in each lobe of the anther, though there may be two only, or there may be more. Each sporangium has the usual tapetum and wall-layers, and these are eventually more or less absorbed, as are also certain of the tissues of the

Microsporangium.

anther itself betwixt adjacent sporangia, so that their cavities unite. In the ripe anther, therefore, the traces of the original sporangia are somewhat obliterated. The spores are produced in tetrads, each within a sporocyte, by two successive bipartitions of its energid. In monocotyledonous plants each partition is completed by formation of a cell-membrane around the daughter-energids, whilst in dicotyledonous plants the partition of the mother-energids into four daughter-energids is effected before these are invested by cell-membrane—a hastening of development observable also elsewhere. The spores when mature commonly become separated one from the other, but may remain united in tetrads, which may themselves remain coherent. Even when isolated the spores do not always form a dry powder, but may be entangled by connecting threads of the debris of the sporangial and antherine tissue. Of various shapes, the mature spores have the usual wall of two layers, here called the *exine* and *intine*. The exine, more or less cuticularized, may be smooth, but more frequently exhibits a pattern through local thickenings, and there are usually small areas where it is thin and less cuticularized, the so-called *germ-pores*, through which the intine, which is a delicate cellulosic membrane, will protrude in the later germination of the spore. All these conditions of shape, pattern, freedom, coherence of the spores, are of infinite variety; in this respect they markedly contrast with the spore-features in the Pteridophytes, and find their explanation in the work of pollination. Whilst still within the pollen-sac the spore reaches a stage of development at which its germination can begin. Its energid divides, but the daughter-energids are not of equal dimensions, and neither of them in Dicotyledones becomes invested by cell-membrane; in Monocotyledones this may be formed. One, the larger, has a purely nutritive destiny, and is termed therefore the *vegetative energid*; the other, smaller, is the mother of the male gametes, and is termed the *generative energid*. In many dicotyledonous plants this generative energid divides in the spore to form two daughter-energids, each of which is a functional male gamete, and the spore therefore within the pollen-sac contains three energids. In monocotyledonous plants this further division of the generative energid may be postponed to a later phase of germination. These changes within the pollen-grain present us with the reduced homologues of the male gametophyte and its products in the Pteridophytes, and the reduction is much greater than in Gymnosperms. The pollen-grain in this condition is ready for pollination, and unless this occurs no further change normally takes place in it, although if the pollen-grains within the anther be wetted, say by rain, one or more futile pollen-tubes may be sent out. It is to guard against this that so many protective arrangements to the pollen are provided in the flower.

The destiny of the ovule as the nursery of the embryo in Spermophytes imposes the necessity of a more elaborate

Megasporangium.

construction than is found in megasporangia unconnected with seed-formation, and this finds expression in its envelopes and the water-carrying system and food-store they provide. The ovule arises as a cellular papilla upon the placenta, and as it gradually acquires its mature form, from atropous to anatropous, and with or without a conspicuous *funicle*, its *nucellus* becomes invested by one or two envelopes, the *integuments*, which, growing out from beneath its base, form, by their upward extension, a *micropyle* at its apex. The vascular bundle-system of the placenta is prolonged into the base of the nucellus, but future nucellar development precludes its further extension therein; it is therefore arrested expanding to a varying degree, or it spreads with often intricate ramifications in the integu-

ment—usually in the outer if there be two. These integuments are then ovular (sporangial) outgrowths which primarily construct the normal channel of entrance of the pollen-tube, and permit of the elaboration of the water-carrying system of the ovule, but, retaining more or less their meristematic character, they subsequently, when sharing in the formation of the seed-coat, alter their structure and may form *arils* of kinds. In holoparasites which form ovules the integument is often absent. In most gamopetalous Dicotyledones there is only one, but in Monocotyledones and most polypetalous Dicotyledones there are two. The significance of this is not apparent. That the integuments are structures of slight phyletic import is shown not only by their somewhat varied structure and points of origin, but by the fact that in some families, for instance, the Ranunculaceæ and the Rosaceæ, genera are unitegminous, whilst others are bitegminous. As the nucellus develops, spore-formation proceeds within it. The sporogenous tissue is usually a short sub-apical hypodermal axile row of cells, one of which becomes the megaspore or embryo-sac. There are in some cases several embryo-sacs which may develop, up to a certain point, when one takes the lead and the others are absorbed by it. The embryo-sac begins to enlarge at a very early period of the growth of the nucellus and elongates in the axis of this and towards its base, absorbing the nucellar tissue. It also enlarges laterally by the same method. As its enlargement proceeds, so do changes in its energid, which divides in the transverse plane of the sac. The daughter-energids recede to the respective poles of the elongated sac, and there each divides by two successive bipartitions to form a group of four. Of the basal polar group three invest themselves with cell-membrane and constitute the *antipodal cells* of the mature embryo-sac, the fourth moves upwards towards the equator of the sac. Of the apical polar group three remain at the apex, but do not invest themselves with cell-membrane, and constitute the so-called *egg-apparatus*, one of them larger than the others being the *female gamete* or *egg*, the others the *synergidæ* or *help-cells*; the fourth, which is the sister of the egg, moves downwards towards the equator of the sac, and meets the detached fourth member of the basal polar group, with which it sooner or later coalesces to form the *definite energid of the embryo-sac*. Viewing the embryo-sac as a megaspore, an obvious interpretation of these changes within it is that they are the consequence of its germination, and are therefore the homologues of the endospermic prothallus of Gymnosperms and of the female gametophyte in the Pteridophytes; this explanation has received very general acceptance. The antipodal cells would be cells of a reduced prothallus; of the three energids of the egg-apparatus, one alone is normally functional as the egg, but the synergidæ may, it has been said, function as eggs. The crux is, however, the interpretation of the definite energid, and its formation has been explained as a case of reinvigoration of a decadent vegetative organ by coalescence similar to what is frequently observed elsewhere in the plant kingdom, notably amongst the Fungi. It would be then an element of the prothallus. Other interpretations have traced a sexual act, and a conjugation of male and female gametes in the formation of the definite energid, or a concrescence of two female gametes. It is, however, unnecessary to discuss these, because recent researches have brought to notice altogether new facts in the history of the changes in the embryo-sac in fertilization, and to them reference will presently be made; these, though they do not clear up the difficulties of interpretation of the formation of the definite energid, must be taken as a starting-point in any explanation that may be advanced. The embryo-sac in most ovules has arrived at the stage of development above

described when pollination is effected. But this is not always the case. The embryo-sac may not be formed, the ovule itself may hardly be visible when the pollen-grain reaches the style, and in these cases it is through the stimulus of the growth of the pollen-grain that the changes in the embryo-sac are initiated.

The pollen-grains escape from the anther by its rupture through differences in drying between its epidermal layer and the fibrous wall of the pollen-sacs within.

Pollination.

As a rule the pollen-grains are simply exposed by this rupture, but in other cases the relations of the stamens and the flower-envelopes give rise to an explosive mechanism, brought into action either from the inside by the natural expansion of the flower, or by mechanical disturbance from without, by which the pollen-grains, which in such a case are always dry and powdery, are shot out to some distance from the flower. The destination of the pollen-grains is the stigmatic surface of the carpel, to which they cohere partly through the viscid secretion exuded from it, partly through entanglement amongst the stigmatic papillæ, and to this outgrowths of the exine may contribute. The proximity of the stamens and carpels in a hermaphrodite flower, and the fact of their ripening, as is common, at the same time, render possible the direct application of the pollen to the stigma either by contact of anther and stigma, by its falling from anther upon stigma, or in other ways, within the one flower. This is *self-pollination*, and it takes place undoubtedly with frequency in nature, and may be said to be the *raison d'être* of the hermaphrodite flower. It is often called *self-fertilization* or *autogamy*, but in using these terms and other terms of similar form, and they are common, it must be remembered that pollination is only a spore-distribution, and a step on the way towards the accomplishment of the sexual act which is *fertilization*, and which indeed may not result after pollination. When the flowers are unisexual, whether on the same plant (*monoecism*) or on separate ones (*dioecism*), such facile pollination is precluded, and it must be effected by the conveyance of pollen from the stamens of one flower to the stigma of another. This is *cross-pollination*, often termed *cross-fertilization* or *alogamy*. Experiment has, however, shown that even in hermaphrodite flowers cross-pollination may be the more effective process in its ultimate result after fertilization has been effected, and that the progeny of a cross-pollinated hermaphrodite flower is often better than that of one self-pollinated. Cross-pollination is also frequently preferred even when the flower is hermaphrodite and self-pollination might be possible, for there are arrangements of different kinds which may either altogether prevent self-pollination or at least promote cross-pollination in the first instance. Thus the relative position of anthers and stigma and the form of the pollen may be such as to place a barrier to self-pollination (*hercogamy*), or the periods of rupture of anthers and of maturation of stigma may be different (*dichogamy*, either *protandrous* or *protogynous*). At the same time, in many hermaphrodite flowers which are normally cross-pollinated, self-pollination becomes possible before withering, and may take place should cross-pollination have failed. On the other hand, there are flowers which are so constructed as entirely to exclude the chance of cross-pollination, inasmuch as they do not open, and self-pollination is therefore a necessity (*cleistogamy*). The agencies by which cross-pollination is effected in Geophytes are wind and animals, and their flowers have been classed as *anemophilous* and *zooidiophilous*, in conformity with their adaptation to pollination by one or other of these agencies.

Anemophilous flowers are characterized by the prodigal pro-

duction of powdery pollen, much of which never reaches its proper destination, and the pollen-grains themselves are smooth and light. The anthers as the distributing organs are freely exposed, and the outgo of the pollen-grains in suitable weather is facilitated by such means as the assemblage of the flowers in catkins, their hanging from slender pedicels, long slender filaments to the anther, explosive mechanisms in the flower, and similar arrangements. The reception of the pollen is aided by a free and extensive entangling stigmatic surface, produced by copious branching of the style. Bright colours, nectar-glands giving honey, odour, and generally conspicuousness, are more or less absent. Many flowers, however, which are anemophilous may be also zooidiophilous. There is no doubt that the fertilization of many flowers is effected by animals in their transit over the areas upon which the plants are growing. Such pollinations are, however, entirely fortuitous. On the other hand, the majority of flowers are regularly visited by insects of many kinds, and these insects effect pollination. Such flowers are entomophilous, and are the chief zooidiophilous ones. Here conspicuousness of some kind is a primary requirement for the securing of insect-visits, and this may be effected in various ways, for example, by size and form of individual flower, by aggregation of flowers in inflorescences, by coloured and glistening surfaces in the flower or in the neighbouring parts. Doubtless the most potent lure is odour, and alike in connexion with it and with colour it is probable our senses do not appreciate scents and colours which are recognizable by insects. The gain to the insect by its visit is the honey, which is often protected in elaborate fashion, so that only insects of special form can secure it, and the pollen itself. In seeking for the honey the insect becomes dusted with pollen-grains from the anthers—which are found in positions in relation to the whole form of the flower such that this dusting of the body of a suitable insect is readily effected, the pollen-grains themselves having commonly more or less tuberculated surfaces, and being somewhat sticky—and it carries them to the stigma of flowers subsequently visited. Birds sometimes effect pollination of flowers (*ornithophilous*), snails are also sometimes the agents (*maalophilous*), and other animals—in all of these cases the attraction of food brings the animal to the flower. The relationships of flowers to animals, especially insects, are infinite in variety, and are the subject of a copious literature. Pollination by insects is a prevalent method of cross-pollination at the present epoch, and stands in correlation with the evolution of the angiospermous flower. It is manifestly a more certain and more economical one than pollination by wind. Its hazard is the absence of the proper insect, especially in cases where the form-development is such that but few species of insects can effect it. Pollination by wind is a more primitive method. Pollination in the ways described must often result in the application of pollen-grains of one species upon the stigma of another. Such foreign pollen is frequently sterile upon the stigma, and no result follows. There is also a prepotency in its own pollen belonging to every species, and the application of one grain of it will render futile the germination of any foreign pollen upon its stigma. If such pollination by foreign pollen is followed by the completion of the sexual act, and an embryo is formed, the offspring will be a *hybrid*. In nature such hybrids between allied forms are common, and they are readily produced in cultivation. They may in time be the starting-point of specific forms. Generic hybrids are not so common in nature, but in certain families of Angiosperms quite a number have been produced in horticultural practice.

Methods of cross-pollination.

Pollination having been effected, the pollen-grain moistened by the viscid secretion upon the stigma resumes active growth. The intine investing the vegetative energid is protruded through one of the germ-pores as the pollen-tube, and apparently under chemiotactic influence grows downwards through the style, dissolving its tissue by the aid of an enzyme. The vegetative energid is found at the tip of the tube, and in dicotyledonous plants is followed out of the spore by the male gametes, in monocotyledonous plants by the generative energid which then divides in the tube and forms a pair of gametes. The pollen-tube reaches the cavity of the ovary and commonly passes along the placenta, guided by projections or hairs, to the micropyle of the ovule; this it enters, and dissolving its way through any cells of the nucellus intervening between it and the apex of the embryo-sac, it pierces the latter. This piercing, however, is not always necessary, for the egg-apparatus may have developed so as to rupture the embryo-sac, and even the apex of the

Second germination of microspore.

nucellus, so that it projects into or beyond the micropyle. By this time the two male gametes have passed the degenerated vegetative energid and are at the apex of the tube, and this now being softened they escape into the plasm of the embryo-sac. The gametes, as observed in recent investigations, have vermiform nuclei somewhat thickened at the end, and exhibit a finely porose structure; they are not unlike the spermatozooids of some Pteridophytes, and they are sometimes so named, but their independent movement, without or by means of cilia, has not been observed. One of the male gametes thus discharged, reaches the egg and impregnates it. The fate of the other was until recently not traced, and it was supposed to disintegrate in the plasm of the embryo-sac, or occasionally to coalesce with synergidæ. We now know, however, that in several plants it passes downwards, perhaps passively transported by the streaming of the protoplasm in the embryo-sac, to the two polar energids which have not yet coalesced, and it unites with the apical polar one, or it may await their coalescence, and then unite with their combination—the definite energid of the embryo-sac. The fusion of the second male gamete apparently precedes the impregnation of the egg by the first male gamete. This remarkable *double fertilization* as it has been called, although only recently discovered, has been proved to take place in widely separated families, and both in Monocotyledones and Dicotyledones, and there is every probability that, perhaps with variations, it is the normal process in Angiosperms. It gives a history of the second male gamete. Whilst the pollen-tube normally reaches the apex of the embryo-sac through the micropyle (*acrogamy* or *porogamy*), it may pierce the embryo-sac at the chalazal end or at the side (*basigamy* or *chalazogamy*) by entering the base of the nucellus and making its way upwards, using as passages, it may be, the cavities of aborting embryo-sacs. After impregnation the fertilized egg segments to form the embryo, the synergidæ having long before disintegrated, and the impregnated definite energid also enters sooner or later upon division which results in the formation of endosperm; the antipodal cells often disintegrate at the same time, though they may undergo multiplication first. It has long been known, that after fertilization of the egg has taken place the formation of endosperm begins from the definite energid, and this had come to be regarded as the commencement of the development of prothallus after a pause following the reinvigorating union of the polar energids. This view is still maintained by those who differentiate the two fertilizations within the embryo-sac, and regard that of the egg by the first male gamete, as the true or generative fertilization, and that of the polar energids by the second male gamete as a vegetative fertilization which gives a stimulus to development in correlation with the other. If, on the other hand, the endosperm is the product of an act of fertilization as definite as that giving rise to the embryo itself, we have to recognize that twin plants are produced within the embryo-sac—one, the embryo, which becomes the angiospermous plant, the other, the endosperm, a short-lived undifferentiated nurse to assist in the nutrition of the former, even as the subsidiary embryos in a pluriembryonic Gymnosperm may facilitate the nutrition of the dominant one. If this is so, and the endosperm like the embryo is normally the product of a sexual act, hybridization will give a hybrid endosperm as it does a hybrid embryo, and herein (it is suggested) we may have the explanation of the phenomenon of xenia observed in the mixed endosperms of hybrid races of maize and other plants regarding which it has only been possible hitherto to assert that they were indications of the extension of the influence of the pollen beyond the egg and its product. This would not, how-

ever, explain the formation of fruits intermediate in size and colour between those of crossed parents. The signification of the coalescence of the polar energids is not explained by these new facts, but it is noteworthy that the second male gamete is said to unite sometimes with the apical polar energid, the sister of the egg, before the union of this with the basal polar one. The idea of the endosperm as a second subsidiary plant is no new one; it was suggested long ago in explanation of the coalescence of the polar energids, but it was then based on the assumption that these energids were male and female gametes, for which there was no evidence, and which was inherently improbable. The proof of a coalescence of the second male gamete with the definite energid gives the conception a more stable basis.

By the segmentation of the fertilized egg, now invested by cell-membrane, the embryo-plant arises. A varying number of transverse segment-walls transform it into a *pro-embryo*—a cellular row of which the micropylar cell becomes attached to the apex of the embryo-sac, and thus fixes the position of the developing embryo, and the terminal cell is projected into its cavity. In Dicotyledones the shoot of the embryo is wholly derived from the terminal cell of the pro-embryo, from the next cell the root arises, and the remaining ones form the *suspensor*. In many Monocotyledones the terminal cell appears to form the cotyledonary portion alone of the shoot of the embryo, its axial part and the root being derived from the adjacent cell; the cotyledon would thus be a terminal structure and the apex of the primary stem a lateral one—a condition in marked contrast with that of the Dicotyledones. It is known, however, that in many Monocotyledones the cotyledon is not really terminal. The primary root of the embryo in all Angiosperms points towards the micropyle. The developing embryo at the end of the suspensor grows out to a varying extent into the forming endosperm, from which by surface absorption it derives plastic material for growth; at the same time the suspensor probably plays a direct part as a carrier of nutrition and may even develop, where perhaps no endosperm is formed, special absorptive “suspensor roots” which invest the developing embryo or pass out into the body and coats of the ovule, or even into the placenta. In some cases the embryo or the embryo-sac sends out haustoria into the nucellus and ovular integument. As the embryo develops it may absorb all the plastic material available, and store either in its cotyledons or in its hypocotyl what is not immediately required for growth as reserve-food for use in germination, and by so doing it increases in size until it may fill entirely the embryo-sac; or its absorptive power at this stage may be limited to what is necessary for growth and it remains of relatively small size, occupying but a small area of the embryo-sac which is otherwise filled with endosperm in which the reserve-food is stored. There are also intermediate states. The position of the embryo in relation to the endosperm varies, sometimes it is internal, sometimes external, but the significance of this has not yet been established. *Apogamy* sometimes occurs in Angiosperms. As a rule the embryonic shoots are developed from the nucellar wall, or from the synergidæ, or from the antipodal cells, and polyembryony is the result. In *Erythronium*, however, polyembryony is the result of a process recalling features of Gymnosperms, for the embryos arise from the segmentation of the terminal cell of the suspensor—that which normally produces the one embryo. True parthenogenetic apogamy is said to occur in *Antennaria alpina*.

The formation of endosperm starts, as has been stated,

from the definite energid of the embryo-sac, and the process of double fertilization above described gives new interest to its development. The segmentation of the fertilized definite energid always begins before that of the egg, and thus there is timely preparation for the nursing of the young embryo. If in its extension to contain the new formations within it the embryo-sac remain narrow, endosperm formation proceeds upon the lines of a cell-division, but in wide embryo-sacs the endosperm is first of all formed as a colony of energids (œnobium), and only gradually acquires a pluricellular character, the change starting from the sides or ends of the embryo-sac. The function of the endosperm is primarily that of nourishing the embryo, and its basal position in the embryo-sac places it favourably for the absorption of plastic material entering the ovule. Its duration varies with the precocity of the embryo. It may be wholly absorbed by the progressive growth of the embryo within the embryo-sac, or it may persist as a definite and more or less conspicuous constituent of the seed. When it persists as a massive element of the seed its nutritive function is usually apparent, for there is accumulated within its cells reserve-food, and according to the dominant substance it may be starchy, oily, cellulosic, aleuronic, and so forth. In cases where the embryo has stored reserve-food within itself and thus provided for self-nutrition, such endosperm as remains in the seed may take on other functions, for instance that of water-absorption.

As the development of embryo and endosperm proceeds within the embryo-sac, its wall enlarges and commonly absorbs the substance of the nucellus (which is likewise enlarging) to near its outer limit, and combines with it and the integument to form the *seed-coat*; or the whole nucellus and even the integument may be absorbed. In some plants the nucellus is not thus absorbed, but itself becomes a seat of deposit of reserve-food constituting the *perisperm* which may coexist with endosperm, or may alone form a food-reserve for the embryo. Endospermic food-reserve has evident advantages over perispermic, and the latter is comparatively rarely found and only in non-progressive series. Seeds in which endosperm or perisperm or both are said to exist are commonly called *albuminous*, those in which neither is found are termed *exalbuminous*. These terms, extensively used by systematists, only refer, however, to the grosser features of the seed, and indicate the more or less evident occurrence of a food-reserve; many so-called exalbuminous seeds show to microscopic examination a distinct endosperm which may have other than a nutritive function. The character of the seed-coat bears a definite relation to that of the fruit which is derived from the ovary, and it may be from accessory parts as well. Their function is the twofold one of protecting the embryo and of aiding in dissemination; they may also directly promote germination. If the fruit is a dehiscent one and the seed is therefore soon exposed, the seed-coat has to provide for the protection of the embryo and may also have to secure dissemination. On the other hand indehiscent fruits discharge these functions for the embryo, and the seed-coat is only slightly developed.

Dissemination is effected by the agency of water, of air, of animals—and fruits and seeds are therefore grouped in respect of this as hydrophilous, anemophilous, and zooidiophilous. The needs for these are obvious—buoyancy in water and resistance to wetting for the first, some form of parachute for the second, and some attaching mechanism or attractive structure for the third. The methods in which these are provided are of infinite variety, and any and every

part of the flower and of the inflorescence may be called into requisition to supply the adaptation. Special outgrowths, *arils*, of the seed-coat are of frequent occurrence. In the feature of fruit and seed by which the distribution of Angiosperms is effected we have a distinctive character of the class. In Gymnosperms we have seeds, and the carpels may become modified and close around these, as in *Pinus*, during the process of ripening to form an imitation of a box-like fruit, which subsequently opening allows the seeds to escape; but there is never in them the closed ovary investing from the outset the ovules, and ultimately forming the groundwork of the fruit.

Their fortuitous dissemination does not always bring seeds upon a suitable nidus for germination, the primary essential of which is a sufficiency of moisture, and the duration of vitality of the embryo is a point of interest. Some seeds retain vitality for a period of many years, though there is no warrant for the popular notion that genuine "mummy wheat" will germinate; on the other hand some seeds lose vitality in little more than a year. Further, the older the seed the more slow as a general rule will germination be in starting, but there are notable exceptions. This pause, often of so long duration, in the growth of the embryo between the time of its perfect development within the seed and the moment of germination, is one of the remarkable and distinctive features of the life of Spermophytes. The aim of germination is the fixing of the embryo in the soil, effected usually by means of the root, which is the first part of the embryo to appear, in preparation for the elongation of the epicotyledonary portion of the shoot, and there is infinite variety in the details of the process. In albuminous Dicotyledones the cotyledons act as the absorbents of the reserve-food of the seed and are commonly brought above ground (*epigeous*), either withdrawn from the seed-coat or carrying it upon them, and then they serve as the first green organs of the plant. The hypocotyl commonly plays the greater part in bringing this about. Exalbuminous Dicotyledones usually store reserve-food in their cotyledons, which may in germination remain below ground (*hypogeous*). In albuminous Monocotyledones the cotyledon itself, probably in consequence of its terminal position, is commonly the agent by which the embryo is thrust out of the seed, and it may function solely as a feeder, its extremity developing as a sucker through which the endosperm is absorbed, or it may become the first green organ, the terminal sucker dropping off with the seed-coat when the endosperm is exhausted. Exalbuminous Monocotyledones are either hydrophytes or strongly hygrophilous plants and have often peculiar features in germination.

It has been possible here only to depict what appear to be general features of sexual reproduction in Angiosperms, and these after all rest upon observation within only a limited circle of forms. A new chapter in the history of our knowledge of the changes in the embryo-sac is opened by the discovery of double fertilization, and the whole subject requires reinvestigation.

Distribution by seed appears to satisfy so well the requirements of geophilous Angiosperms that distribution by vegetative buds is only an occasional process. At the same time every bud on a shoot has the capacity to form a new plant if placed in suitable conditions, as the horticultural practice of propagation by cuttings shows; in nature we see plants spreading by the rooting of their shoots, and buds we know may be freely formed not only on stems but on leaves and on roots. Where detachable buds are produced, which can be transported through the air to a distance, each of them is an incipient shoot which may

Germination of seed.

Agamogenetic reproduction.

have a root, and there is always reserve-food stored in some part of it. In essentials such a bud resembles a seed. A relation between such vegetative distribution buds and production of flower is usually marked. Where there is free formation of buds there is little flower and commonly no seed, and the converse is also the case. Viviparous plants are an illustration of substitution of vegetative buds for flower.

II. *Aerophytes*.—The ecological category of *Aerophytes* is a much smaller one than that of *Geophytes*, and, unlike the latter, they are not affected by edaphic environment. An *aerophyte* is an autotrophic plant growing upon another, to which it is commonly fixed by its roots. The term *epiphyte*, commonly given to them, is so frequently used to designate the position of saprophytes and parasites upon host-plants, that it is better avoided as the name of the ecological category we are dealing with. *Aerophytes* are found amongst both *Dicotyledones* and *Monocotyledones* and in many families. They may be herbs, shrubs, or trees. They are derived from *geophytes*, and their mode of life, while it enables them to reach better conditions of light, makes them dependent wholly upon epedaphic environment, and their distribution over the world is markedly contingent upon a supply of atmospheric moisture. Their home is the damp woods of the tropics and of the warm temperate regions. The conditions of life of an *aerophyte* make its supply of water somewhat precarious; it has therefore to provide for the protection of what it secures, and for the rapid absorption of any coming within reach. For the former of these purposes it most commonly has some form of water-storage which gives it succulence in leaf or stem; the cuticle is thick and the stomata are sunk, and a coating of hairs is found occasionally though rarely. For the latter purpose the roots, which are frequently copious, often have a velamen; exposed to light they form chlorophyll and become accessory organs of carbon-dioxide-assimilation, or they may take on the whole duty of this, the leaves being then suppressed. Sometimes in rootless forms absorptive hairs enable the plant to take water by its whole surface. The seed of an *aerophyte* usually germinates upon the supporting plant, and it is rare for a *geophyte* subsequently to become an *aerophyte*; on the other hand several cases are known of a juvenile *aerophyte* becoming a *geophyte* when older, and smothering its nurse as it descends to the soil. These plants are therefore only *hemiaerophytes*. In some *aerophilous* Bromeliads the rosette of leaves forms a cup in which water collects; into this débris both organic and inorganic falls, and produces a nutrient solution in which hydrophytes like *Utricularia* may live. The Bromeliad absorbs this fluid by special hairs, and is therefore a partial saprophyte; its roots are only anchoring organs. Such plants are called *Tank Aerophytes*. A somewhat similar condition, differing only in soil being collected instead of water, is seen in *Nest Aerophytes*. Here some roots or leaves form, with the stem of the supporting plant, a receptacle in which débris accumulates and makes a soil into which feeding roots from the *aerophyte* pass; in this case there is an approach to the *geophytes*. Many *aerophytes* have brilliant flowers highly specialized for entomophilous pollination. The seeds are small and light, or have flight arils or a succulent fruit-envelope, and can readily enter a crack of tree-bark. Dissemination is anemophilous or zooidiophilous, sometimes also the rain may be the agent. Vegetative propagation hardly exists, but portions of the shoot of *Tillandsia usneoides* are said to be carried by wind and birds.

III. *Hydrophytes*.—Plants of the ecological category of *Hydrophytes* dwell in a more uniform environment than

is the lot of *Geophytes* or *Aerophytes*, and hydrophilous features are found in many cycles of affinity amongst *Dicotyledones* and *Monocotyledones*. Typical hydrophytes live submerged in water. Their general physiognomy is that of delicate flexible herbs which rapidly shrivel on exposure to the air. In their environment their water-supply is not a first charge upon the organization, because diffusion can take place at every point, but the gaseous supply, owing to the slow diffusion of air in water, and the supply of radiant energy, owing to the feeble penetration of light, are matters of first moment. Further, the density of the medium reduces the need of intrinsic support. To those conditions hydrophytes are adapted first of all by an extension of the shoot-surface, secured by elongation of the leaves into a riband form in moving water, or by their division into filiform segments in still water; at the same time the system of air-canals is greatly developed. Then the chlorophyll apparatus lies in the peripheral layers of the organism, palisade-tissue being absent, and the strengthening tissue is always reduced in amount, and so forth. In the absence of transpiration there is a reduction or, it may be, a suppression of the root-system, and it is often only developed as an anchoring organ. No stomata are formed upon the shoot, and the cuticle is everywhere only feebly formed. The carrying system too is greatly simplified, both by reduction of the number of vasa and of their area, and it is concentrated as a central strand in the axis, just as it is in ordinary roots, and thus is favourably placed in relation to the pulling strains to which the shoot is subjected under the currents of water. The growing points are frequently invested by mucilage, which acts as a protection to them. Many of these features of hydrophytes are observable in hydrophilous *geophytes*, and there are all stages of transition between the two types. Thus when in hydrophytes the flowers are brought above the surface of the water, one or more flat floating leaves may be developed to support the plant at the surface, or the floating leaves may predominate. Floating plants also occur in which the leaves are variously modified to act as floats. In all cases where parts of the shoot reach the air they develop more or less *geophytic* features. Amongst the most remarkable of hydrophytes are the *Podostemaceæ*—tropical dicotyledonous plants of cascades and rapidly flowing water. They have the habit of *Bryophytes*. The root forms a branched dorsiventral chlorophyllous thallus-like structure, attached by hairs and special branches (*haptera*) to rocks, and it is the chief structure for the assimilation of carbon dioxide. The shoots, which are also commonly dorsiventral, arise as outgrowths from it and bear small, usually divided, leaves. Marine hydrophytes which are subject to exposure between tides have often some of the xerophilous features of halophytes. In their flower-structure typical hydrophytes show great simplification where the flowers are persistently submerged. They are frequently unisexual and the flower-envelopes are reduced. For subaqueous pollination the pollen is often vermiform of about the same specific gravity as the water, whilst the styles are long and filiform so as to increase the chances of the act being accomplished. Sometimes pollination takes place on the surface of the water, and then in various ways the pollen is brought to the surface, where it comes in contact with the stigmas. Often the flowers are raised in the air above the water, and then they exhibit the features of anemophily or zooidiophily. Many hydrophytes have embryos of peculiar form and remarkable germination. Amongst *Monocotyledones* most hydrophytes are exalbuminous and the embryos are macropodous through storage of food-material. Vegetative propagation by the detachment of portions of the shoots or of definite buds is not uncommon amongst hydrophytes, and these, readily

carried by water-currents, serve as a means of distribution. To this circumstance is probably due the wide area of distribution of many hydrophytes.

A typical Angiosperm is an *autotrophic* (prototrophic) plant. By this we mean that it is able to build up its organic food-material within itself from inorganic substances taken by it from without. In the early juvenile phases of their life, however, many such autotrophic Angiosperms are *heterotrophic*, that is to say, they take in their organic food-material from without, inasmuch as they feed in germination upon reserve-food stored up within the seed, frequently by means of a special sucker produced by the cotyledon. This is after all only a case of prolongation of the nursing process common to all embryos, and of the drawing of food from one set of cells to another which is characteristic of the higher plants in consequence of their colonial organization. On the other hand some Angiosperms are persistently heterotrophic, either as *saprophytes* (metatrophic) or as *parasites* (paratrophic), and this manner of life involves some kind of *symbiosis*. Between truly autotrophic Angiosperms and truly heterotrophic ones there are all degrees, and such intermediate forms have been designated *mixotrophic*.

A typical saprophyte is a plant which derives its food-material from dead organic matter. This method of feeding is associated with the presence of the mycelium of a fungus attached to the absorbing system and forming a *mycorrhiza*, and there is a *reciprocal symbiosis* between the Angiosperm and the fungus which is *endophytic*, only rarely *ectophytic*. Reduction of the vegetative system of the Angiosperm accompanies this. The subterranean portion of the plant is small and the roots may be absent. In the shoot chlorophyll is suppressed, and commonly a brown pigment, the use of which is unknown, is present; there are only scale-leaves, and the carrying system is rudimentary. Such typical saprophytes are *holosaprophytes*. Where chlorophyll is present in small amount the plant is able to manufacture some at least of its carbonaceous food and is then a *hemisaprophyte*. Angiospermous holosaprophytes are not common. They are known amongst Gentianæ and Monotropæ only of Dicotyledones, and most of them are Monocotyledones of the Orchidæ, Burmanniaceæ, and Triuridæ. They are derived from autotrophic forms and do not appear to be associated with any special climatic conditions, but, as their structure would suggest, are most of them plants of shade and moisture. A large number of Angiosperms which appear to be independent autotrophic forms are now known to engage in a form of symbiosis, the exact relations in which are not yet determined. More or fewer of their rootlets have their extremities invested by a web of hyphal mycelium as an *ectophytic mycorrhiza*. This is not constant in one species, nor do all rootlets of one plant show it. Its frequency, however, indicates some reciprocal relation between the Angiosperm and the fungus. The occurrence of *Mycodomatia* upon the roots of plants of Leguminosæ as well as of other families is a result of a symbiosis, and is of supreme importance in agriculture on account of the accumulation of nitrogenous material that takes place within them. The fact known to gardeners that, as the wood of tubs in which large plants are grown gradually decays, the roots of the occupant spread into it and there develop *mycorrhiza*, usually *endophytic*, points in the direction of the facultative saprophytism of all Angiosperms. The habit possessed by a few plants of different cycles of affinity of capturing insects in traps of various kinds, enables them to obtain an accession to their supply of nitrogen. In some of them a proteolytic enzyme brings about the digestion of the insect for the benefit of the plant (Droseraceæ, Nepenthaceæ), in other cases there appears to be no enzyme, and the plant absorbs soluble nitrogenous substances formed in normal putrefaction (Sarraceniaceæ). Some carnivorous plants are hydrophytes (Utricularia). The flower-structure of typical saprophytes has no feature of special interest, but it is much to be wished that we had full knowledge of the changes in the embryo-sac and of the phases of embryogeny.

A parasite takes all or a portion of its food-material from a living *host* into which it penetrates. The degree of connexion between the two and the dependence of the parasite upon the host vary between the completeness of that of *holoparasitic* Rhizanthæ, in which little more than the flower of the parasite is visible upon the outside of the stem of the host and the parasitism is absolute, and the limitation of that of the *hemiparasitic* Rhinanthæ, in which to all appearance there is an

independent autotrophic geophyte, for it possesses chlorophyll and its union with the host is confined to isolated points below ground. The seat of attachment of the parasite may be either the root or the stem of the host; sometimes, in the case of twining parasites, the leaf may also be made use of. In the simplest cases the parasite develops a sucker (*haustorium*), from the centre of which piercing connexions of kinds proceed, and it then maintains its individual shoot development, which may be that of a herb (annual or perennial), shrub, tree, or liane, outside the host. But in the more advanced conditions of parasitism the reduction of the vegetative system of the parasite is so great that its individuality outside the host is lost, and it appears as a web of threads running within and blending with the tissues of the host, in the manner of a mycelium, or forming with the tissue of the host a tuberosous conjoint stock from which the reproductive system shoots. All Angiospermous parasites are derived from autotrophic forms, but the modification in the form and structure of their organs—both vegetative and reproductive—induced by the parasitism, makes the relation of holoparasitic groups somewhat obscure. Parasitism is unknown amongst Monocotyledones, but has appeared more than once amongst Dicotyledones. Cytinæ, Balanophoræ, Orobanchaceæ, Lennoaceæ, are families of differing position which are characteristically holoparasitic. Loranthaceæ and Santalaceæ are chiefly hemiparasitic, as are most of the parasitic Scrophularinæ. Parasitism is not associated with any special epedaphic conditions, and there are no hydrophilous parasites. It occurs in all regions of the world, and in the varying environment of dark damp tropical woods, arid plains of warm regions, tropophil woods of temperate regions, and Alpine slopes. Accordingly both xerophilous and hygrophilous features appear. The host in some cases seems to have no particular attraction to the parasite, and any species of plant may be used by the same specific parasite, even its own body being acceptable; on the other hand, there are parasitic species which are only known upon one kind of host. Of the factors which co-operate in bringing about the attachment of a parasite to its host we know nothing beyond the fact that chemiotactic and contact stimuli are, as in all cases of infection, concerned in it. The life of the host may or may not be affected by the parasite. Species of *Cuscuta*, if they do not kill, may so arrest the growth of their host-plant as to bring about results disastrous in agriculture, and by the penetration of loranthaceous plants deformities of stem and branches are produced in trees, which then become useless for timber. It has been claimed that in the case of chlorophyllaceous parasites, the symbiosis may not be *antagonistic* but *reciprocal*, but even if this be so to some extent, the amount of aid rendered to the host does not compensate for the drain upon its resources made by the parasite. So conspicuous is this that legislation restricting the cultivation of mistletoe, on account of the damage caused by it in orchards, has been deemed necessary in some districts in Europe. In the more recently derived parasites, those of bicarpellate gamopetalous Dicotyledones, most of which are hemiparasitic and epiphizal, the flower-structure and seed-formation retain in the main their immediate ancestral features, but in the families of the Loranthales, to which all evidence concurs in ascribing a far back origin, many modifications in the way of reduction are found. The inflorescence may be endogenetic, the ovule may consist of nucellus alone, and frequently there is no ovule—the embryo-sacs, of which there are many, being then developed in the torus or in the ovarian wall. The formation of endosperm offers many features of interest, one of the most remarkable being that seen in *Balanophora*, where the apical polar energid alone of the energids within the embryo-sac survives disintegration, and then, in the absence of fertilization, segments to form a pluricellular endosperm upon which an embryo apogamously buds. The history of few forms is well known, and these require re-study in the light of the recently-acquired knowledge of fertilization. There is no more promising field for investigation than that of the embryogeny of parasites.

Intimate relations between Angiosperms and the animal kingdom have been shown to exist in the work of pollination, of dissemination, and of the feeding of carnivorous plants. Another relation of which the *Myrmecophily* facts are clear enough, but of which the evolution is doubtful, is that known as *Myrmecophily*. Species of ants make their home on tropical plants, living in hollows of stem, petiole, or stipule, which are commonly enlarged and may form tuberosous cushions. They feed upon either the secretion of extra-floral nectaries, or upon the richly nitrogenous contents of modified glands (*Müller's corpuscles*), which are borne upon some part of the leaves, and which are continuously renewed during the life of the leaf. These ants act as a bodyguard to their home against the inroad of leaf-cutting ants collecting material for their fungus-gardens. These remarkable relationships have naturally led to the assumption that there is causal connexion between the ants and the

plant-structures, a view for which there is, however, no sufficient evidence.

The position of Angiosperms as the highest plant-group is unassailable, but of the point or points of their origin from the general stem of the plant kingdom, and of the path or paths of their evolution, we can as yet say little. Until well on in the Mesozoic period geological history tells us nothing about Angiosperms, and then only by their vegetative organs. We readily recognize in them now-a-days the natural classes of Dicotyledones and Monocotyledones, distinguished alike in vegetative and in reproductive construction, yet showing remarkable parallel sequences in development; and we see that the Dicotyledones are the more advanced and show the greater capacity for further progressive evolution. But there is no sound basis for the assumption that the Dicotyledones are derived from Monocotyledones; indeed, the palæontological evidence seems to point to the Dicotyledones being the older. This, however, does not entitle us to assume the origin of Monocotyledones from Dicotyledones, although there is manifestly a temptation to connect helobitic forms of the former with ranal ones of the latter. There is no doubt that the phylum of Angiosperms has not sprung from that of Gymnosperms.

Within each class the flower-characters as the essential feature of Angiosperms supply the clue to phylogeny, but the uncertainty regarding the construction of the primitive angiospermous flower gives a fundamental point of divergence in attempts to construct progressive sequences of the families. Simplicity of flower-structure has appeared to some to be always primitive, whilst by others it has been taken to be always derived. There is, however, abundant evidence that it may have the one or the other character in different cases. Apart from this, botanists are generally agreed that the concrescence of parts of the flower-whorls—in the gynæceum as the seed-covering, and in the corolla as the seat of attraction, more than in the andrœcium and the calyx—is an indication of advance, as is also the concrescence that gives the condition of epigyny. Dorsiventrality is also clearly derived from radial construction, and anatropy of the ovule has followed atrophy. We should expect the albuminous state of the seed to be an antecedent one to the exalbuminous condition, and the recent discoveries in fertilization tend to confirm this view. Amongst Dicotyledones the gamopetalous forms are admitted to be the highest development and a dominant one of our epoch. Advance has been along two lines, markedly in relation to insect-pollination, one of which has culminated in the hypogynous epipetalous bicarpellate forms with dorsiventral often large and loosely arranged flowers, and the other in the epigynous bicarpellate small-flowered families of the *Aggregatæ*. In the polypetalous forms progression from hypogyny to epigyny is generally recognized, and where dorsiventrality with insect-pollination has been established, a dominant group has been developed as in the *Leguminosæ*. The starting-point of the class, however, and the position within it of apetalous families with frequently unisexual flowers have provoked endless discussion, and there is no uniformity in opinion upon these matters. In Monocotyledones a similar advance from hypogyny to epigyny is observed both in a geo-aerophilous and in a hydrophilous series, but the class does not appear to be now progressive. In this connexion it is noteworthy that so many of the higher forms are adapted as bulbous geophytes, or as aerophytes to special xerophilous conditions. The *Gramineæ* offer a prominent example of a dominant self-pollinated or wind-pollinated family, and this may find explanation in a multiplicity of factors.

From an early period in the century systematists have been endeavouring to group the families of the two classes of Angiosperms in larger associations under such designations as Alliance, Cohort, Series, and such endeavours were in the direction of discovering real phyla—although in the pre-Darwinian period the idea was not always present. The relationship of some families is so clear that there has never been any doubt about their forming phyletic groups, but on the other hand there are many, either isolated or of reduced type, the position of which has been and in very many cases is still open to discussion, and consequently the limits of these phyla—like the limits of families, genera, and species—have been variously assigned by different botanists according to their particular views and to the knowledge of their time. The arrangement by botanists of these phyla in

larger groups has given us different systems which, if they all lay claim to associating in some measure natural groups, vary in the degree to which convenience or genetic relation—real or imagined—has influenced them. In Great Britain the system adopted by Bentham and Hooker—itsself framed upon that of De Candolle, which in turn owed its origin to Jussieu—holds sway, with some modification, fortified as it is by the detailed description in their magnificent work—the *Genera Plantarum*—of all genera known at the time of writing. It is:—

Dicotyledones.

POLYPETALÆ { *Thalamifloræ.*
Discifloræ.
Calycifloræ.

GAMOPETALÆ { *Inferæ.*
Heteromera.
Bicarpellatæ.

MONOCHLAMYDEÆ.

GYMNOSPERMÆ.

Monocotyledones.

The inclusion of Gymnosperms amongst Dicotyledones was more a conforming with conventional practice than the expression of an opinion of genetic relationships which were recognized as cryptogamic. Apart from this, the grouping in the Polypetalæ and Gamopetalæ indicates in the main the lines of progression of Angiosperms; the juxtaposition of *Inferæ* and *Calycifloræ* being adopted to bring into prominence the similarities of facies between the flower-features of the highest Polypetalæ and the aggregate Gamopetalæ. The Monochlamydeæ, on the other hand, was retained as a convenient group for apetalous and often unisexual families, the relationships of many of which were and are doubtful, although the connexion of some of them with polypetalous families was clearly pointed out. In Germany there has recently been completed *Die Natürlichen Pflanzenfamilien*—a book made possible by Bentham's and Hooker's labours—the combined work of many botanists under the editorial guidance of Engler and Prantl. It gives brief diagnoses of all known genera. The system adopted in it is:—

Dicotyledones.

AROHICHLAMYDEÆ (*Choripetalæ* and *Apetalæ*).

METACHLAMYDEÆ (*Sympetalæ*).

Monocotyledones.

In this system the *Apetalæ* disappear as a group, and the families are assigned their positions in the several phyla or series, as they are termed, to which in the views of the writers they belong. The series are arranged in genetic sequence, so far as a linear arrangement permits of this, beginning with *Casuarinæ* and *Piperacæ*, which are regarded as the most primitive forms extant. As an attempt at a phylogenetic arrangement this system is now preferred by many botanists, particularly in America. More recently a startling novelty in the way of system has been produced by Van Tieghem, as follows:—

Monocotyledones.

Liorhizal Dicotyledones.

Dicotyledones.

INSEMINÆ.

SEMINEÆ.

Unitegmineæ.

Bitegmineæ.

The most remarkable feature here is the class of Liorhizal Dicotyledones, which includes only the families of *Nymphæacæ* and *Gramineæ*. It is based upon the fact that the histological differentiation of the epidermis of their root is monocotyledonous, whilst they have two cotyledons—the old view of the epiblast as a second cotyledon in *Gramineæ* being adopted. But recent investigation shows that the embryo of *Nymphæacæ* is monocotyledonous, and the adult root-character is only confirmation of this, and whatever the epiblast be it is not a constant feature of grass-embryos. Ocular characters determine the grouping in the Dicotyledones, Van Tieghem supporting the view that the integument, the outer if there be two, is the lamina of a leaf of which the funicle is the petiole, whilst the nucellus is an out-growth of this leaf, and the inner integument, if present, an indusium. The *Inseminæ* include forms in which the nucellus is not developed, and therefore there can be no seed. The plants included are, however, mainly well-established parasites, and the absence of nucellus is only one of those characters of reduction to which parasites are liable. Even if we admit Van Tieghem's interpretation of the integuments to be correct, the diagnostic mark of his unitegminous and bitegminous groups is simply that of the absence or presence of an indusium, not a character of great value elsewhere, and, as we know, the number of the ovular coats is inconstant within the same family. At the same time the groups based upon the integuments are of much the

same extent as the Polypetalæ and Gamopetalæ of other systems. We do not yet know the significance of this correlation between number of integuments and union of petals.

Angkor, Wat. See SIEMRAT and CAMBODIA.

Anglesea or Anglesey, an insular county of North Wales, separated from Carnarvon by the narrow channel known as the Menai Strait.

Area and Population.—The area of the ancient and administrative county is 175,836 acres or 275 square miles, with a population in 1881 of 51,416, and in 1901 of 50,590, the number of persons per square mile being 184, and of acres to a person 3.48. The area of the registration county is 120,199 acres with a population in 1891 of 34,219. Within this area the increase of population between 1891 and 1901 was 1.0 per cent. The excess of births over deaths between 1881 and 1891 was 2392, and the decrease in the resident population was 908. The following table gives the number of marriages, births, and deaths, with the number and percentage of illegitimate births for 1880, 1890, and 1899:—

Year.	Marriages.	Births.	Deaths.	Illegitimate Births.	
				No.	Per-centage.
1880	217	1023	1023	74	7.3
1890	199	800	729	73	9.1
1899	241	894	592	58	6.5

In 1891 there were in the county 129 natives of Scotland, 409 natives of Ireland, and 71 foreigners, while 2509 could speak English, 23,200 Welsh, and 7281 English and Welsh.

Constitution and Government.—Anglesea returns one member to parliament, and it has now no parliamentary borough. There is one municipal borough, Beaumaris (2310). The following are urban districts: Holyhead (10,072), Llangefni (1751), and Menai Bridge (1600). It is in the North Wales circuit, assizes being held at Beaumaris. There are forty-four ecclesiastical districts or parishes, all in the diocese of Bangor.

Education.—The number of elementary schools on 31st August 1899 was 64, of which 39 were board and 25 voluntary schools, the latter including 22 Church of England schools, 1 Roman Catholic, and 2 "British and other." The average attendance at board schools was 4060, and at voluntary schools 2330. The total school board receipts for the year ending 29th September 1899 were over £14,242. The income under the Agricultural Rates Act was £825.

Agriculture.—About six-sevenths of the total area of the county is under cultivation, and of this, more than half is in permanent

Year.	Area under Cultivation.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1880	147,011	26,389	9,468	26,431	84,389	333
1885	148,006	26,639	10,004	27,203	83,975	185
1890	149,451	26,188	10,062	31,724	81,421	50
1895	152,004	24,798	9,305	28,219	89,592	76
1900	152,478	21,712	9,095	44,721	76,810	107

pasture. Less than 8000 acres are hill pasture, and only a little more than 2000 acres are under woods. Almost the whole acreage

under corn crops is occupied by oats; more than half the green crop acreage is under turnips, and considerably more than a fourth under potatoes. A few acres of flax are usually grown. The preceding table gives the larger main divisions of the cultivated area at intervals of five years from 1880.

The following table gives particulars regarding the principal live stock for the same years:—

Year.	Total Horses.	Total Cattle.	Cows and Heifers in Milk or in Calf.	Sheep.	Pigs.
1880	7108	43,740	15,047	46,735	13,986
1885	7040	47,299	16,299	47,268	15,579
1890	6947	47,753	15,951	64,382	20,028
1895	7604	49,249	15,884	59,315	18,560
1900	8367	56,553	17,264	82,145	15,438

Industries and Trade.—According to the report for 1898 of the chief inspector of factories (1900), the total number of persons employed in 1897 in textile and non-textile factories and workshops was 997, the number in 1896 being 929; 751 of the 997 were engaged in non-textile factories. The mining industries have been gradually declining, and in 1899 only employed 549 persons. Copper has almost ceased to be worked, but some zinc is still obtained. In 1899 there were raised 61,557 tons of limestone and 23,711 of sandstone.

Fish are plentiful round the whole coast. The fish landed at Holyhead in 1899 amounted to 17,708 cwt., valued at £3288; and the total value, including shell-fish, was £3562.

Angleur, a town of Belgium, 3 miles by rail S.E. of Liège on the river Vesdre. It is the headquarters of the mining association known as the *Vieille Montagne*, which has zinc foundries here. Population (communal) (1866), 2554; (1880), 4357; (1890), 5902; (1897), 8001.

Anglican Communion.—The Anglican communion consists of the churches of England and Ireland, the Scottish Episcopal Church, and the daughter churches which have sprung from them and are in full communion with them; chief amongst these latter being, of course, the Protestant Episcopal Church of the United States of North America. Until the 19th century these latter were so few in number and so insignificant in size that such a phrase might well have seemed needless: to-day the churches of the Anglican Communion are a power throughout the world. Together they constitute one of the three great historical divisions of Christendom; the others, of course, being the churches of the Roman obedience and those of the Orthodox east. The church of England was already, in the 8th century, a "mother of churches" on the mainland of Europe, through the work of Willibrord, Boniface, and their followers: after this, however, it suffered from the general stagnation, so far as aggressive work was concerned, which overtook most of western Christendom. Nor did it readily emulate the example of missionary activity shown in the 16th century by the Jesuits. Some care was taken to provide for the immediate spiritual needs of English colonists in America, and many isolated efforts were made to convert the Indians. But the predominant Calvinistic theology was not conducive to missionary work, whilst supposed legal difficulties, and the current theory of Church and State, long prevented the consecration of bishops for the Colonies. Archbishop Laud attempted to obtain a bishop for Virginia. A nomination was actually made by Charles II., and other efforts were put forth in the early part of the 18th century; but they all came to nothing. In spite of increasingly urgent petitions, the Colonies still remained unprovided for. Meanwhile they were theoretically under the care of the bishops of London, who from time to time sent commissaries to America, and ordained young men who were sent to England for the

purpose. At length came the War of Independence; and as soon as peace was declared, the church people of Connecticut sent Dr Samuel Seabury to England with a petition to the archbishop of Canterbury for his consecration. But as there were, not unnaturally, political obstacles, Archbishop Moore refused; and they were compelled to turn to the Scottish bishops, by three of whom Dr Seabury was consecrated bishop of Connecticut on 14th November 1784. Soon afterwards, at the initiative of the archbishop, the supposed legal difficulties were removed (26 Geo. III. c. 84); and on being satisfied as to the doctrines of the church, and as to the liturgical changes which were then under discussion in a convention at Philadelphia, the two English archbishops proceeded to consecrate William White and Samuel Prevoost to the sees of Pennsylvania and New York on 14th February 1787. Thus the Protestant Episcopal Church in the United States was properly equipped; and since then its progress has been constant. At the time of Seabury's consecration there were barely 100 Anglican clergymen in the United States: to-day there are in all 91 American bishops and over 5000 clergymen, working either at home or abroad. The American church has never proceeded to the organization of provinces. The presiding bishop is the senior by consecration, and the House of Bishops elects its own chairman.

On 12th August 1787 Dr Charles Inglis was consecrated bishop of Nova Scotia, with jurisdiction over all the British possessions in North America. In 1793 the see of Quebec was founded; Jamaica and Barbadoes followed in 1824, and Toronto and Newfoundland in 1839. Meanwhile the needs of India had been tardily met, on the urgent representations in Parliament of William Wilberforce and others, by the consecration of Dr T. F. Middleton as bishop of Calcutta, with three archdeacons to assist him in his labours. In 1817 Ceylon was added to his charge; in 1823 all British subjects in the East Indies and the islands of the Indian Ocean; and in 1824 "New South Wales and its dependencies"! Some five years later, on the nomination of the Duke of Wellington, William Broughton was sent out to work in this enormous jurisdiction as Archdeacon of Australia. Soon afterwards, in 1835 and 1837, the sees of Madras and Bombay were founded; whilst in 1836 Broughton himself was consecrated as first bishop of Australia. Thus down to 1840 there were but ten colonial bishops; and of these several were so hampered by civil regulations that they were little more than government chaplains in episcopal orders. In April of that year, however, Bishop Blomfield of London published his famous letter to the archbishop of Canterbury, declaring that "an episcopal church without a bishop is a contradiction in terms," and strenuously advocating a great effort for the extension of the episcopate. It was not in vain. At a meeting held at Willis's Rooms in London, early in 1841, the plan was taken up with enthusiasm, and large subscriptions were promised; and on Whitsun Tuesday of that year the bishops of the United Kingdom met and issued a declaration which inaugurated the Colonial Bishops Council. Subsequent declarations, in 1872 and 1891, have served both to record progress and to stimulate to new effort; and since 1841 a sum of about £800,000 has been raised and applied to this object. The diocese of New Zealand was founded in 1841, being endowed by the Church Missionary Society through the Council, and George Augustus Selwyn was chosen as the first bishop. Since then the increase has gone on, as the result both of home effort and of the action of the local churches. Thus St John's Kaffraria was founded by the Scottish Episcopal Church; the foundation of a

see in Japan by the Canadian church is in contemplation; and the colonial churches have all done their share. Moreover, the fuller realization of the nature and value of the episcopal office has led to the sending out of bishops to inaugurate new missions, instead of waiting until there is already a large body of clergy and lay people: this procedure has been followed in the cases, amongst others, of the Universities' Mission to Central Africa, Lebombo, Corea, and New Guinea; and the missionary jurisdictions so founded develop in time into dioceses. And thus, instead of the ten colonial jurisdictions of 1841, there are now about a hundred foreign and colonial jurisdictions, in addition to those of the church of the United States. The see of Carpentaria in Australia was founded in 1900, and scarcely a year passes without the addition of one or more to the list. It was only very gradually that these dioceses acquired legislative independence and a determinate organization. At first, sees were created and bishops were nominated by the Crown by means of letters patent; and in some cases an income was assigned out of public funds. In fact, such was the theory of the crown officers as to its inherent rights as the "fount of honour" that Bishop Selwyn only managed by great exertions to prevent the insertion of a clause in his own letters patent reserving the appointment of his archdeacons to the Crown! Moreover, for many years all bishops alike were consecrated in England, took the customary "oath of due obedience" to the archbishop of Canterbury, and were regarded as a species of extra-territorial suffragans of his. But by degrees changes have been made on all these points.

(1) Local conditions soon rendered necessary something of the nature of a provincial organization, and it was gradually introduced. The bishop of Calcutta received letters patent as metropolitan of India when the sees of Madras and Bombay were founded; and fresh patents were issued to Bishop Broughton in 1847 and Bishop Gray in 1853, as metropolitans of Australia and South Africa respectively. Similar action was taken in 1858, when Bishop Selwyn became metropolitan of New Zealand; and again in 1860, when, on the petition of the Canadian bishops to the Crown and the colonial legislature for permission to elect a metropolitan, letters patent were issued appointing Bishop Fulford of Montreal to that office. Since then metropolitans have been chosen and provinces formed by regular synodical action. The process has been greatly encouraged by the resolutions of the Lambeth conferences on the subject; and in 1901 the formation of a province of Queensland was in contemplation, with Brisbane as its metropolitan see. The constitution of these provinces is not uniform. In some cases, as South Africa, New South Wales, and Queensland, the metropolitan see is fixed: a practice which is not only in accordance with most ancient precedents, but which secures the inestimable benefit of an unbroken history. Elsewhere, as in Canada and New Zealand, where no single city can claim pre-eminence, the metropolitan is either elected or else is the senior bishop by consecration, whatever his see may be. Two further developments must be mentioned. (a) The creation of diocesan and provincial synods, the first diocesan synod to meet being that of New Zealand in 1844, whilst the formation of a provincial synod was foreshadowed by a conference of Australasian bishops at Sydney in 1850. (b) In recent years the title of *archbishop* has been given to the metropolitans of several provinces. It was first assumed by the metropolitans of Canada and Rupert Land, at the desire of the Canadian General Synod, in 1893; and subsequently, in accordance with a resolution of the

*The
Church
in the
Colonies.*

*Provincial
organ-
ization.*

Lambeth Conference of 1897, it was given to the metropolitans of New South Wales and South Africa by their synods. Civil obstacles have hitherto delayed its adoption by the metropolitan of India.

(2) By degrees, also, the colonial churches have been freed from their rather burdensome relations with the state. The church of the West Indies was disestablished and disendowed in 1868 (ESTABLISHMENT). In 1857 it was decided, in *Regina v. Eton College*, that the Crown could not claim the presentation to a living when it had appointed the former incumbent to a colonial bishopric, as it does in the case of an English bishopric. In 1861, after some protest from the Crown lawyers, two missionary bishops were consecrated without letters patent for regions outside British territory: C. F. Mackenzie for the Zambezi region and J. C. Patteson for Melanesia, by the metropolitans of Cape Town and New Zealand respectively. In 1863 the Privy Council declared, in *Long v. The Bishop of Cape Town*, that "the Church of England, in places where there is no church established by law, is in the same situation with any other religious body." In 1865 it adjudged Bishop Gray's letters patent, as metropolitan of Cape Town, to be powerless to enable him "to exercise any coercive jurisdiction, or hold any court or tribunal for that purpose," since the colony of South Africa already possessed legislative institutions when they were issued; and since there was no formal compact of obedience between them, his deposition of Bishop Colenso was declared to be "null and void in law." This apparent disaster, as Bishop S. Wilberforce at once foresaw, proved to be "the charter of freedom of the colonial church." The South African bishops forthwith surrendered their patents, and formally accepted Bishop Gray as their metropolitan, an example followed in 1865 in the province of New Zealand. In 1862, when the diocese of Ontario was formed, the bishop was elected in Canada, and consecrated under a royal mandate, letters patent being by this time entirely discredited. And when, in 1867, a coadjutor was chosen for the bishop of Toronto, an application for a royal mandate produced the reply from the Colonial Secretary that "it was not the part of the Crown to interfere in the creation of a new bishop or bishopric, and not consistent with the dignity of the Crown that he should advise Her Majesty to issue a mandate which would not be worth the paper on which it was written, and which, having been sent out to Canada, might be disregarded in the most complete manner." And at the present day the colonial churches are entirely free in this matter. This, however, is not the case with the church in India. Here the bishops of sees founded down to 1879 receive a stipend from the revenue (with the exception of the bishop of Ceylon, who no longer does so). They are not only nominated by the Crown and consecrated under letters patent, but the appointment is expressly subjected "to such power of revocation and recall as is by law vested" in the Crown; and when additional oversight was necessary for the church in Tinnevely, it could only be secured by the consecration of two assistant bishops, who worked under a commission from the archbishop of Canterbury which was to expire on the death of the bishop of Madras. Since then, however, new sees have been founded which are under no such restrictions; by the creation of dioceses either in native states (Travancore and Cochin), or out of the existing dioceses (Chota Nagpur, Lucknow, &c.). In the latter case there is no legal subdivision of the older diocese, the new bishop administering such districts as belonged to it under commission from its bishop, provision being made, however, that in all matters ecclesiastical there shall be no appeal but to the metropolitan of India. But this is an obvious

anomaly, and it is likely that matters will be simplified in the future.

(3) By degrees, also, the relations of colonial churches to the archbishop of Canterbury have changed. It was at first assumed, as has been said, that a colonial bishop was an extra-territorial suffragan of the archbishop. Until 1855 no colonial bishop was consecrated outside the British Isles, the first instance being Dr MacDougall of Labuan, consecrated in India under a commission from the archbishop of Canterbury; and until 1874 it was held to be unlawful for a bishop to be consecrated in England without taking the suffragan's oath of due obedience. This necessity was removed by the Colonial Clergy Act of 1874 (37 and 38 Vict. c. 77, sec. 12), which permits the archbishop at his discretion to dispense with the oath. This, however, has not been done in all cases; and as late as 1890 it was taken by the metropolitan of Sydney at his consecration. But natural as it is that the oath should be taken by a colonial bishop holding mission from the archbishop of Canterbury, that it should be taken by the suffragan of another province, or still more by a metropolitan, is an obvious anomaly, and one which will doubtless be modified in course of time. Thus the constituent parts of the Anglican communion gradually acquire autonomy: missionary jurisdictions develop into organized dioceses, and dioceses are grouped into provinces with canons of their own. But the most complete autonomy does not involve isolation. The churches are in full communion with one another, and act together in many ways; missionary jurisdictions and dioceses are mapped out by common arrangement, and even transferred if it seems advisable: e.g., the diocese Honolulu (Hawaii), hitherto under the jurisdiction of the archbishop of Canterbury, was transferred in 1900 to the church of the United States on account of political changes. There is a strong affection for and deference to the see of Canterbury, which shows itself by frequent consultation and interchange of greetings; there is also a strong common life which has been emphasized in recent years by common action (LAMBETH CONFERENCES), and seems likely to be even more significant in the future.

Spiritual autonomy.

The Anglican Communion consists of the following: (1) The Church of England, 2 provinces, Canterbury and York, with 23 and 10 dioceses respectively. (2) The Church of Ireland, 2 provinces, Armagh and Dublin, with 7 and 6 dioceses respectively. (3) The Scottish Episcopal Church, with 7 dioceses. (4) The Protestant Episcopal Church of the United States, with 81 dioceses and missionary jurisdictions, including North Tokyo, Kyoto, Shanghai, Cape Palmas, and the independent dioceses of Hayti and Brazil. (5) The Canadian Church, consisting of (a) the province of Canada, with 10 dioceses; (b) the province of Rupert Land, with 8 dioceses, of which 2, Saskatchewan and Calgary, are at present united. (6) The Church in India and Ceylon, 1 province of 11 dioceses. (7) The Church of the West Indies, 1 province of 8 dioceses, of which Barbadoes and the Windward Islands are at present united. (8) The Australian Church, 1 province of 6 dioceses and 9 (at present) unorganized dioceses, which, however, are united under the General Synod of Australia. (9) The Church of New Zealand, 1 province of 6 dioceses, together with the missionary jurisdiction of Melanesia. (10) The South African Church, 1 province of 10 dioceses, with the two missionary jurisdictions of Mashonaland and Lebombo. (11) Nearly 30 isolated dioceses and missionary jurisdictions holding mission from the see of Canterbury.

Anglican Orders.—The attacks which Roman Catholic controversy has made upon the orders of the English Church have varied greatly in character, and shifted their ground from time to time; but all may be

reduced to two classes: (i.) historical objections, and (ii.) ecclesiastical objections.

(i.) The difficulty began with the repudiation of papal supremacy by Henry VIII., when, according to Roman theory, the English Church became schismatical and its orders marred by the taint of schism. A further alienation took place when the Edwardine English ordinal of 1550 and 1552 superseded the old Latin pontifical, and orders were thereupon conferred by a newly-reformed rite. At Mary's accession the pontifical was restored, and eventually Cardinal Pole reconciled the English Church with the Holy See. The exact effect of his action is a matter of controversy. There is no question that he reconciled the schism to the Pope's satisfaction, and therefore that objection to the Henrician and Edwardine orders came to an end; but it is a disputed question both how he was authorized by his papal faculties to deal with the orders conferred by the Prayer Book rite and, also, how in fact he did deal with them. Historical inquiry shows that for a short period before Pole's advent a small number of reordinations took place, but subsequently they almost entirely ceased; and it is contended that in other cases the orders were tacitly allowed, possibly after some slight supplemental ceremony, and that Pole's instructions were designedly vague. The contention is supported by the fact that, while a vast number of parochial clergy were deprived in 1553-54, no case is known of a deprivation on the ground of Edwardine orders. In answer to this Anglican contention an attempt is made to extract from Pole's instructions a definite condemnation of the Edwardine orders, and to maintain that all such clergy as were allowed to minister in Mary's reign must have been reordained. When the Prayer Book was restored under Elizabeth the question returned again, and there is no doubt that since the latter half of the 16th century the Roman Catholics have continually treated Anglican orders as null and void. Still there was no adverse decision. The orders were vaguely attacked, and after 1570 reordinations took place abroad, and in 1608 at Rome; but there was little definite justification offered for this till the Nag's Head fable was invented in 1604, and it was seriously maintained that Archbishop Parker—the main channel of Elizabethan orders—had had no better consecration than a mock ceremony in a tavern. This fable has had great influence on the controversy. In 1616 doubts were cast on the consecration of Barlow, Parker's chief consecrator. There was more justification for this, but both these historical objections have broken down. They were not, as it now appears, seriously entertained at the first official inquiries into the question at Rome in 1685 and 1704; and though they survived until recently as large factors in popular controversy, they bid fair now to disappear, and the battle is shifted to other ground.

(ii.) The theological or ecclesiastical objections fall into three classes. First and earliest came the objection to the orders on the ground of the repudiation by the English Church of the theory of papal supremacy. This has figured largely in the earlier and the less scientific phases of the controversy; but, accurately speaking, it is no objection to the validity but only to the regularity of the orders, and it merely forms part of the general subject of the relation of the English Church to the Papacy, and affects Anglican orders on the same ground as the orders of the Orthodox Church. The other two points touch the question of the ordinal in English, which in 1550 took the place of the old English pontificals in Latin, and with slight modifications remains the ordinal of the Anglican communion to-day. Objection is raised to this on the ground: (a) that it is, in "form," deficient in the

essentials required for a valid ordination; and (β) that the "intention," which lies behind it, and with which the Church uses it, is also deficient. (α) The criticism of the "form" of the ordinal has taken many shapes, and several charges have been made, only to be withdrawn as inadmissible. It has been maintained that the mere giving up of the Latin pontifical was in itself a final departure from the "form of the Church": but the Church Catholic has no one single form for holy order; it has used, and still uses, many forms. The absence of any "porrection of instruments" after 1552 has been made a grave objection, because Eugenius IV. defined this (1439) to be the essential matter of ordination. But his definition was never universally accepted, and since the work of Père Morin (1686) has been recognized to be erroneous. Other and more subtle objections to the Anglican form have been raised ever since the question was first officially examined at Rome in 1685, and again for the Gordon Case in 1704. The documents of these two inquiries have been only recently and incompletely published, and the precise nature of the objections raised is not clear. But they were probably the same as those raised in the bull *Apostolicæ Curæ* in 1896, viz., that the words accompanying the imposition of hands are an insufficient form to define the action which is going on. Attention is called to the fact that the words were made more explicit (both for priests and bishops) at the revision of the Prayer Book in 1661. To this it is replied: that the alteration was made to refute a Presbyterian construction of the forms; that the defining is at least as clear as in the Roman rite, where no words at all necessarily accompany the imposition of hands; that the whole service defines beyond any doubt what the action is, and what the order is that is being conferred; and that the mere imperative formulæ of 1550 do in fact define the order in Biblical terms, and are more explicit than some of the early ordination prayers, which do not define at all. All these objections as to "form" are comparatively modern, for the English ordinal was used in Edward's time by some of the Marian bishops; and even according to the most modern papal interpretation of Pole's instructions it would seem that orders conferred by them using this form were to be held valid, i.e., the form was in itself not insufficient. The Roman attack is thus inconsistent with itself, as well as with the Roman rite and the history of Roman ordinations. (β) The question of intention is raised partly as a general objection, and partly with reference to the actual ordinal and the Anglican doctrine of orders. To the general objection that unsoundness of views invalidates the ordinations, it is replied—first, that this is not true of individual views, but that the intention to be taken into account is the intention of the Church; and, secondly, that the general intention of the English Church with regard to orders is expressed in the preface to the ordinal as an intention to continue in valid sequence the orders that have been in the Church since apostolic times, and is therefore unexceptionable. Further, the special objection is raised that the English Church fails to express the intention in the case of the priesthood, because it makes no special mention at the ordination of the power of offering sacrifice. To this it is replied that—first, such mention is only a mediæval addition to the Latin pontifical, and therefore is unessential; and, secondly, the ordinal mentions the whole work of the priesthood, and not only one side of it, and thus expresses a more comprehensive and fuller intention than the Latin pontifical.

The controversy is thus still undecided. The Roman decision has not met with full approval from learned men in that communion, and has been repudiated not only by Anglican but by Orthodox writers.

The older phases of the controversy have been superseded by recent action at Rome and in England. The older books which still are valuable are two:—On the Roman side—ESTCOURT, *Question of Anglican Ordinations*, 1893; on the English side—DENNY and LACEY, *De Hierarchia Anglicana*, 1895, and *Supplement*, 1896. The latest phase begins with the publication of the bull *Apostolicæ Curæ*, Rome, 1896. The principal pamphlets and books are:—On the Roman side—*A Vindication of the Bull*, by the Roman Catholic bishops, 1898; BRANDI, *Roma e Canterbury*, Rome, 1897; on the English side—*The Answer of the Archbishops of England*, 1897; *A Treatise on the Bull*, 1896; and *Priesthood in the English Church*, 1898; A. BULGAKOFF, *Question of Anglican Orders*, 1899. These three are tracts xix., xli., and liv. of the *Church Historical Society*. Also, A. LOWNDES, *Vindication of Anglican Orders*, 2 vols. New York, 1897, is a useful general summary.

(W. H. F.)

Angling.—Strictly speaking, angling should mean the capture of fish with the hook, as distinguished from netting, spearing, or trapping; for “angle” is an old English word applied to the hook, which in very ancient times appears to have been made in angular form. Such angular hooks are still used by the natives in tropical seas. In modern times, however, angling is the term used to denote the various forms of fishing, recognized as sportsmanlike, with rod, line, and hook.

The principal British fishes which are sought after by the sportsman naturally divide themselves into two classes. In the first class are the members of the salmon family which yield sport to the fly-fisher; namely the salmon itself, the sea-trout, the brown trout, and the grayling. To these may perhaps be

Fly-taking fish.

added the char; but this very delicate and highly esteemed fish, in English waters at any rate, rises badly, and is not often caught except on spinning baits fished at a considerable depth. In Scandinavia, on the other hand, it rises exceedingly well in many lakes, and grows to a large size. The smelt is also a member of the salmon family, and ascends rivers to spawn, but it can hardly be reckoned among the sportsman’s fish. The second class are commonly spoken of as “coarse fish,” and

Coarse fish.

include those species which are found in most of our rivers, lakes, and ponds. They are the pike, barbel, bream, perch, carp, tench, chub, roach, rudd, dace, and gudgeon. Of these, chub, dace, and rudd yield sport to the fly-fisher, and, in certain waters, roach and even perch will take a fly freely in the summer time. Instances are recorded from time to time of other coarse fish taking flies, but, generally speaking, they are fished for with natural baits of various kinds. Perch, while not despising such baits as worms, feed more particularly on the young of other fish; while the fish of the carp family, which includes the roach, rudd, dace, chub, barbel, bream, tench, and gudgeon, feed mainly on vegetable growths, worms, water insects, and sundry pastes when proffered by the angler, and are usually captured on float or leger tackle, by the process known as bottom-fishing. Pike, on the other hand, are fished for with natural or artificial baits kept in movement a few feet from the bottom if dead, while live baits are usually suspended by a float, or used by means of the paternoster or leger methods, which will be described later.

Returning now to the game fish; the salmon first of all claims our attention by reason of its size, sporting qualities, and excellence as food. This fish is

Salmon.

rapidly disappearing from the rivers of England and Wales, and has seriously diminished in numbers in most of the rivers of Scotland and Ireland. The primary cause of the decrease of salmon is undoubtedly the increase of the population in the British Isles generally, which demands such an increased fish supply that the salmon, which fetches high prices, is eagerly sought

after by professional fishermen and others for the market. The demand is, in consequence, largely in excess of the natural supply; and the natural supply itself is diminished in many cases by pollution which destroys the eggs of the salmon, by manufacturers’ turbines, water-wheels, and other apparatus which destroy the young of the salmon and hinder the travels of the spawning fish up stream; and by the capture by poachers of the large salmon themselves when on the spawning beds. In the sea, in the estuaries of rivers, and even in the narrow fresh-water rivers themselves, salmon are ruthlessly netted for market purposes. It is a striking peculiarity of the salmon that while it must, in view of its rapid growth, feed largely in the sea, it is rarely caught in salt water by the angler. In rivers, on the other hand, where it rises to the angler’s fly and takes his prawn, worm, gudgeon, or other bait, it rapidly gets out of condition and is believed to feed but little. In most salmon rivers there is, as a matter of fact, little food to sustain such large fish. The most sportsmanlike method of catching salmon is undoubtedly with the fly, though, generally speaking; the combination of feathers, tinsel, and wools which go to make up this lure, does not represent any insect known to entomologists. What are termed fancy flies are possibly taken by the fish for the young of some marine creature, or simply for some unknown thing struggling to escape. To the present day trout are fished for in Norway with a piece of red rag trailed behind a boat, and it can hardly be suggested that the fish regard this as any known item of food, or that it is absolutely necessary that artificial flies or baits should represent existing insect or animal life. Grilse, which is the name given to salmon on their first return to the river before spawning, will rise to such flies as the March brown; and even a full-grown salmon will occasionally take quite a small fly. Salmon rise most readily when first leaving the sea and entering the river. After being in fresh water a little time they apparently settle down to a period of inactivity and feed badly, though a rise of water will generally set them moving upwards, and on reaching a new pool they may often be induced to rise. It should be mentioned here that in some rivers salmon are running up from the sea all the year round; and it is one of the problems connected with this remarkable fish to explain why, in the Tay, for instance, it should enter the river in January, seeing that the principal purpose for which it comes into fresh water, namely spawning, is not carried out until the following autumn at the earliest. These January fish, moreover, have apparently not spawned during the months preceding their entry into the river, and unless it is assumed that they are all barren fish, which is unlikely, it would appear that the salmon or some members of the species do not spawn every year. In the majority of salmon rivers there is a spring run of salmon; in July and August shoals of grilse enter the river; while in September there is the autumn run of big fish, which have evidently come up for spawning and no other purpose. About the beginning of September, netting, as a rule ceases, the dates varying in different rivers; but angling with rod and line is still allowed for a few weeks, as otherwise the proprietors of the upper reaches of the river, who protect the salmon on the spawning beds, would obtain no sport at all. In November angling entirely ceases, and the salmon soon go on the gravelly shallows, where the female deposits her eggs, a few of them only being vivified by milt from the male. The fish cover their eggs by sweeping gravel over them. In the course of a few weeks the eggs hatch, and the resulting fry remain in the river about two years, very much resembling the small trout in appearance.

They then begin to grow silvery, descend to the sea herring-size, and return weighing from 3 lb to as much as 14 lb. The salmon on its first return to the river is termed grilse, as we have said; but in Ireland the corresponding name is peal, which should be distinguished from the same word used in the west country, where it is always applied to sea-trout. The capture of the smolts is illegal, but a good many are killed in mistake for trout.

There is an endless variety of flies used for salmon fishing, but the angler need not supply himself with a very great variety, so long as he is provided with flies of various sizes, as size is regarded, by experienced salmon fishermen, as being even more important than colour. Speaking generally, the flies used in early spring are large, and they diminish in size as the season grows older. In autumn quite small flies are used for the fish which have been some time in the river, and, as a general rule, the lower the water, the smaller should be the fly used, and the deeper should it be fished. For very bright weather and clear water, lightly dressed flies, which are mainly light yellow in colour, are standard favourites, such as the Sun-fly and the Mystery. But undoubtedly the most generally favoured of all the salmon flies, and one which can be reasonably relied upon to kill, if dressed of the right size, and if the salmon are in taking humour, is the Jock Scott. It perhaps owes its reputation largely to the fact that it is a particularly suitable fly for use when the rivers are clearing after a spate; and as this is quite the best time for salmon fishing with the fly, the Jock Scott, as a result, kills perhaps more fish than any other fly known to anglers. The tackle of the salmon fly-fisher is simple, but somewhat expensive, as the fish are so strong, and of such value when captured, that to use weak or indifferent tackle is properly regarded as a foolish proceeding. The rod itself may vary in length from 12 feet to 18 feet, according to the strength and height of the user, and is usually made of either split cane, with or without a steel centre, or of greenheart. It should have plenty of wood in the top joint, to give it lifting power. It should bend right away down to the butt when the cast is made, but must on no account be weak in the middle, for the salmon fisher sometimes has to refuse the fish even an inch of line, which places an enormous strain upon the rod. The line is usually of plaited silk, and waterproofed, with an oil dressing. It should be what is termed solid, that is, not plaited round a core, nor with a centre left hollow. At the end of the line comes the 3 yards of strong salmon gut, the upper part of which may be twisted or plaited, and then the fly. In big, fast-running rivers, treble or double gut is sometimes required right down to the fly. Salmon flies are now very commonly tied on eyed hooks, but many salmon fishers believe that they swim better if there is simply a small gut loop whipped on at the end of the shank. To the eye or the loop is tied a short length of gut which, in its turn, is looped on to the cast. There are many kinds of excellent salmon reels made in England, the mechanism of which varies. The angler should see that there is a good strong check, and that the reel itself is strongly made and durable.

In working the salmon fly, the angler fishes either from a boat or from the bank, according to the river, and casts over pools and other places which are known by experience to be frequented by salmon. As a rule, only one fly is used, and the cast is made across and a little down stream, the current bringing the fly round, when the fly is drawn up stream a little and a fresh cast is made. When grilse are in the river two flies are

often used, particularly if the fish run small; and in some pools the flies are cast up stream and drawn quickly down or across, the dropper fly being worked along the surface. There are many rules which are firmly believed in by old salmon fishers, but the salmon are constantly breaking them; as, for instance, by taking a fly floating on the surface, and by rising in pools where, according to local tradition, salmon are never caught. The height of the water has a very great deal to do with success in salmon fishing, and while, at a certain level, certain pools will hold rising fish, if the water falls or rises a little these pools may become useless, and other pools come into play. In big rivers the salmon fly is often harled, that is to say, allowed to trail out behind a boat which is rowed backwards and forwards across the stream, being dropped a few yards at each crossing. By this means the fish sees the fly before being alarmed by the boat passing over it. In lakes salmon are usually fished for with two flies, the dropper being worked along the surface. Both in lakes and rivers, the angler who fishes the hardest, other things being equal, generally succeeds the best; and it must not be supposed that the fish will not rise because the pool has been fished over two or three times. Sooner or later the psychological moment arrives and the salmon rises. When a salmon misses the fly it is good policy to rest him for two or three minutes and then fish for him again, starting a little above him and gradually working down. If he again misses the fly, a smaller size of the same pattern may be tried, and a still smaller one if he rises and misses this. Then other patterns may be tried if necessary. In playing the salmon the rod should be kept well up, with the butt resting against the hip and the left hand grasping the rod a little above the reel. The line should not be touched by the left hand. The right hand should be kept on the handle of the reel, and the line should be wound up at every opportunity, if only a few inches, and allowed to run off the reel if the salmon makes rushes or heavy plunges. The angler should follow the fish, running or walking, as far as the bank will allow, and never give an inch more line than he is obliged to, of course having due regard to the strength of the tackle. If it can be done without bringing the fish into a dangerous position, the salmon should be worked down stream. Thus the angler when playing a salmon maintains a position on the bank a little below the fish if he can. It is an almost impossible thing to draw a very heavy fish up stream against a strong current. A very sulky fish may be handplayed. Salmon are also fished for with various baits, such as the prawn, worm, minnow, stone loach, gudgeon, and artificial spinning baits of which the phantom and spoon are the best. The spinning baits are usually harled in large rivers. The prawn is, as a rule, cast out and allowed to float down stream at about mid-water, but sometimes it is harled. It is a deadly bait in clear water. A bunch of worms is used in thick water, while a single worm on two-hook tackle may be cast up stream in low clear water.

Trout, which most modern authorities consider spring from a common ancestor, vary remarkably in size and appearance. In a Devonshire brook they may average a fifth of a pound, while in lakes they grow to over 20 lb. The Thames grows the largest in England. One was caught in Loch Stennes which weighed 29 lb. A cast of this remarkable fish is preserved in the smoking-room of the Fly-fishers' Club, London. Trout may be divided broadly into two kinds: those which live permanently in river or lake, and those which pass the greater portion of their lives in the sea, visiting the rivers in summer and autumn, and while there pro- Trout.

pagating their species in much the same manner as the salmon. Sea-trout (*Salmo trutta*), sometimes called salmon-trout, and known in Ireland as white trout, of which the bull-trout is a variety, afford sport of the highest class to the fly-fisher. They are found in many salmon rivers and smaller streams, and exhibit a partiality for lakes connected with the sea. They are caught both in the tidal portions of the rivers, and in the upper reaches. Fly-fishing for them is carried on in almost identically the same manner as what is termed wet-fly fishing for brown trout; except where the fish run, large and small salmon flies are used, in which case the flies are cast and worked much as they would be for salmon. Sea-trout

Sea-trout. are notorious short risers, and both for these and for salmon which have been some time in the river and rise warily, a long-shanked double hook, small in the bend, is now largely used. It is known as the Bickerdyke "*Salmo irritans*" hook, *Salmo irritans* being a name humorously conferred upon the fish which just touch the fly without being hooked. Sea-trout are found in the pools of rivers, in small eddies, and generally in many of the places favoured by brown trout; but they show a great partiality for a long rippling run of a few feet in depth, while in the tidal portions of a river a shoal will frequently be found collected round a sandy spit in only a foot or two of water. They are generally fished for with rather gaudy flies with a mixed wing, the body composed of mixed seal's fur (such as olive with a little crimson and blue), with a ribbing of flat silver tinsel and a short red tuft at the tail like the Zulu. They will at times take all the ordinary brown trout and loch flies such as are used both on river and lake, and in tidal pools there are few better flies than a silver-doctor tied exceedingly small, while small Alexandras are also killing. The angler should be guided as to the size of his fly by the nature of the water, in a heavy stream a larger fly being used than in a quiet one; while in the pools, if there is a good ripple, a slightly larger fly should be used than if the ripple is trifling. In lakes, sea-trout are found scattered over all the shallower portions, but favourite spots will be round the edges of weeds and at the inlet and outlet of a stream. Sea-trout will take small spinning baits and worms, and are often fished for with a worm used on spinning tackle. A favourite artificial bait on the east coast rivers of Scotland is a very small tube of india-rubber threaded on a hook, and cast by means of the fly-rod.

So far as fly-fishing is concerned, the non-migratory trout are angled for by two very distinct and characteristic methods. On most of the English south-country rivers, and in not a few of those in the Midlands and farther north, the various flies of the Ephemeridæ family are very abundant, and as they come floating down the river the trout rise to the surface, take up a position, and seize fly after fly. To capture the trout in such circumstances the dry-fly method of fishing has been invented. The flies resemble the natural insect, are tied with cocks' hackles which are somewhat stiff, and are frequently moistened with paraffin to make them float. A single fly is used; the line, a heavy and tapered one, is greased; and the rod is usually a short but powerful weapon of about 10 feet in length. A feeding fish having been marked down, the angler stalks him very carefully, keeping well below him, and casting the fly with great precision about a yard above him so that it floats down over his nose, when the trout may or may not take it. Dry-fly fishing has become exceedingly popular of late years and has many enthusiastic professors. Though imitations of the Ephemeridæ are most generally used, sedges, alders, palmers, and other flies find places in the dry-fly fisher's book; and when the spring fishing

is over most of the trout are caught in the evening by means of sedges of various kinds. In wet-fly fishing the angler regards wind as a necessity on the more quiet pools, but in dry-fly fishing the trout are caught in absolutely calm water. The secrets of success lie, firstly, in being able to mark down feeding fish; in selecting those which are under the bank rather than out in the middle; in keeping within casting distance of the fish without being observed; in choosing the right fly, and casting with precision. The difficulties of capturing fish depend very largely on the amount of fishing done in any particular river. If, for instance, it is a club water which is heavily fished, and large numbers of small trout are constantly being returned, the fish become exceedingly shy and difficult of capture; and it is quite possible that a certain proportion of them, finding surface feeding a dangerous amusement, turn their attention to the vast wealth of crustacean and other natural food which is found among the weeds of the chalk streams. Among the flies which are general favourites with dry-fly fishers are the blue dun, red or claret quill, medium olive quill, iron blue, dark olive dun, gold-ribbed hare's ear, silver sedge, orange sedge, cinnamon quill, little marryat, pale olive quill, detached badger, alder, Wickham's fancy, pink Wickham, and the May-fly.

Wet-fly fishing is more particularly appropriate to streams where there is no considerable amount of surface food, where the water is shallow and of a broken character. Here the trout are ever on the look-out for passing particles of food, and the angler walks up stream casting one, two, or three flies ahead of him, allowing them to drift back with the current and striking if he perceives the least check of the line. On some big rivers, where the water is coloured, it is a common practice to fish down stream with a long line, but the up stream method is generally the most successful. Even in low water, on hot, bright, sunny days, a basket of fish may be made by wading up stream, using a single fly, casting it in little runs behind rocks and stones and in every nook and cranny likely to hold trout; and it is astonishing to find what very small places will hold trout of a very respectable size. In such circumstances down stream fishing would be absolutely useless. For the trout of the smaller English, Irish, and Welsh rivers, and the Scottish burns, very fine tackle should be used, and, within reasonable limits, the lighter the rod the better, for it allows of more delicate manipulation. The trout run small, rarely exceeding half a pound, but the fishing, when there are several miles of breezy moorlands to be walked, is of a very delightful character, and the charm of the surroundings and the healthiness of the exercise will fully compensate for the lack of weight on the part of the quarry. There are some streams which possess the characteristics of both wet-fly and dry-fly waters; such, for instance, is the Dove. Here there are many quiet reaches of no great depth where there is an abundance of surface food, and the dry-fly fisher can pass many happy and profitable hours; while between them there are long rippling shallows, swirling eddies, and miniature falls, where the wet-fly fisher has every opportunity of killing fish with his own particular method. To fish such a river it is desirable that the angler should be acquainted with both methods, using each in its appropriate place. In fact, an angler can hardly be said to be a finished fly-fisher until he is as expert with the dry fly as he is with the wet fly. It is impossible here to give a complete list of the flies used by trout fishermen, but among the general favourites are the red and black palmers, coch-y-bondhu, black gnats, the governor, the coachman, duns of various colours, Greenwell's glory, March brown, redspin-

Dry-fly fishing.

Wet-fly fishing.

Non-migratory trout.

ner, alder, &c. For wet-fly fishing the fly should, as a rule, be sparsely dressed, and the hackles should be soft. For low, bright water, where the fish are at all educated, some of the very best flies are those used on Yorkshire streams. But now and again one happens upon a river where the trout show a decided preference for big heavily-dressed flies: In common language, they appear to like a big mouthful.

Fishing with the May-fly is a thing of itself. On some rivers these large species of the Ephemeriidæ rise in extraordinary quantities, and the trout take them very freely; in fact, in rivers containing coarse fish the trout generally run large, and, as a general rule, refuse the fly at any other time. The big rise of May-fly, however, tempts them to the surface, and a goodly number are captured during the first week or two of June. Like the duns, the May-fly is fished either wet or dry, but more often dry than wet. It sometimes happens, however, that the wet fly will kill better than the dry. As the fly goes through its various changes the artificial should be altered to correspond to it. First we have the greendrake; then this sheds its skin and becomes the greydrake; and, lastly, the greydrake dies and floats down with wings expanded on the water, when it is known as the spent gnat. The fly-fishing on a river is usually rather poor for a week before the May-fly appears and for a week or two after it has disappeared, and by some anglers the presence of the fly is on this account objected to. On the other hand, the May-fly has a splendid feeding effect on the trout, putting them into finest possible condition.

Lake trout, except where there is an abundance of coarse fish or bottom-feeding, generally rise much better to the fly than river trout, and are usually captured when there is a breeze to ripple the water, and the day is not too bright. The fish lie round islands, off rocky points, by the sides of weeds, and over shallow ground generally, but are not much fished for with the fly in the deeper portions unless there is a rise of May-fly or other insects to bring them to the surface. The common practice is to row the boat to windward of some likely spot, then drift over it. The anglers, if there are two, sit at each end of the boat and take alternate casts. Short casts are better than long ones, for the trout will rise close to the boat, and it is, generally speaking, important to let at least one of the flies drag along the surface of the water. When a fish rises at the fly and misses it, he should be cast over again instantly, and may often be caught. Indeed, the writer has on more than one occasion known a fish to rise in front of the boat, miss the fly, the boat go over the fish, and the angler to take a cast behind the boat and secure the trout. Some lakes are not suited for drifting, and it is better for the attendant to row the boat, putting it near likely spots for fish. One great point in successful loch-fishing is to let the wind work the flies as much as possible. This can only be accomplished with rather a long rod, 12 feet or 13 feet being a good length. The line is cast out sideways, and the wind, bearing out the line, drags the flies in the same direction as the boat is drifting. By this means the flies are given the natural motion of drifting with the wind. When they are drawn against the wind the motion is unnatural, and a large fish will often refuse to take them. The flies used in lake fishing are mostly of a fancy character, lake trout showing considerable taste in the matter of colour, to which, in Ireland particularly, great importance is attached. There pigs' wools and silks, furs of various hues, including olives, russets, reds, browns, &c., are used, either alone or mixed. The usual wing is cut from the breast feather of a mallard,

and the hackle, red or black. A fly tied with red body and teal wing is a standing favourite. Large lake trout often show a preference for a claret-bodied fly with a dark mallard wing and black hackle. The size of fly used should vary according to the wave or ripple, and whether the day is bright or otherwise. The rougher and darker the day, the larger and darker the fly. On a bright day, with a small ripple, small brightly-coloured flies should be used. Different lakes, however, have their own peculiarities, and if there is a rise of any particular fly on a lake, that fly should of course be imitated. The moorlands have peculiar flies of their own, and on lakes situated among them, imitations of those flies should, if possible, be used. On several of the big Irish lakes there is a considerable rise of May-fly, when the fish will take the artificial, but are more readily caught with the natural insect, one or two of which are impaled on a No. 6 or No. 7 hook and allowed to drift along the surface, the tackle being simply 2 feet of fine gut, above which is about 10 yards of floss silk, and then a fine running line. With a fair breeze the floss silk can be dispensed with, and an ordinary twisted silk, undressed line used. The most expert lake dappers prefer a short line to a long one. In a very faint air trout may sometimes be caught in this way by tying a goose's breast feather into the floss silk line about 4 feet above the hook. By this means, if the rod is a long one, the May-flies can be got out sufficiently far to secure an occasional rise.

In addition to the fly, the two other most common methods of catching trout are with a natural or artificial spinning bait, and with the worm. The most sportsmanlike of these, in the sense that it requires most skill, is what is termed clear-water fishing with the worm. On three small hooks, placed at short intervals at the end of the cast, and commonly known as Stewart tackle, is impaled a well-scoured red worm, and this, when the water is low and bright, the angler casts, wading up stream and fishing every hole and corner in much the same manner as is already recommended for the single fly, used under similar conditions. Grilse and sea-trout are also caught in this way, and occasionally a salmon. The difficulty, of course, is to cast or swing out the bait without causing it to break away from the hooks. The worming, which is done when the river is in flood, is of a very different character. Here a piece of lead is fixed on the line above a good-sized hook, and a big worm is let down in eddies close to the bank, where sooner or later a fish takes it. Minnows, which may be either imitations such as the phantom or Devon, or the natural minnow fresh from the stream, or one which has been preserved in formalin or other preservative, are cast across the stream, the line being drawn rapidly in towards the angler. About 3 yards of gut is desirable above the bait, and at least 2 yards from the minnow should be placed a very small lead, immediately below which is a double swivel. It is important that the lead should hang a little below the level of the line to prevent it from twisting. This ensures all the spinning taking place below the lead and the swivels doing their duty. A considerably stiffer rod is required for this method than for fly-fishing, as much more pressure is required to get the triangles which are used into the trout than the single hook on which the fly is mounted. In the Thames bleak and small dace are used for spinning, and it is a common practice to use live bait for the larger trout which in that river approximate in size to salmon. The Thames live-bait tackle is extremely simple. It consists merely of a very small cork, nothing being better than that taken from a chemist's vial, with a slit down it in which the line is placed. A yard and a half below this are three or four

Bait fishing for trout.

Thames trouting.

No. 1 shot, and a yard and a half below the shot a lip hook and a small triangle. It will be seen that the bait plays near the surface, for near the surface are the trout when feeding. Success largely depends on knowing the whereabouts of the fish. Many trout take up their position after early spring in the more quiet reaches of the river, but most of the fishing is done in the weir-pools and on the shallows below them.

In lakes, spinning is usually termed trolling, and is commonly carried on by trailing the bait some distance behind the boat. In this case, as there is no casting to be done, the lead should be placed as far as possible from the bait; one of the best tackles for the purpose is a small Chapman spinner. Large trout which are never caught with the fly, except in the May-fly season, may be caught by trolling. They are, as a rule, on the shallows in March and April; about June they begin to move into deeper water and remain there until September, when they are found round the mouths of tributary rivers and streams up which they will by and by run for spawning. The deep waters of lakes are not sufficiently fished, perhaps because the labour of working them properly is considerable. As much as a pound of lead may be required to get down to the depths where the big fish lurk, and so that this lead may not alarm the wary old trout it has to be placed not less than 12 feet from the bait. Among the best baits used are small trout, minnows, gudgeon, bleak, and stone loach (called collocks in Ireland). A fish firmly believed in by many Scottish loch-fishers is *Salmo ferox*, which is caught usually by trolling. It is, as a rule, a big-headed, ugly, dark old fish, and modern ichthyologists are of opinion that it is simply a lake trout of considerable age and usually a male. Trout vary so much in appearance, according to their age, sex, food, and the nature or the soil over which they swim, and other local conditions, that many alleged species have from time to time been discovered, which, in the end, turned out to be simply local varieties of the ordinary brown trout. Rainbow trout (*Salmo irideus*) have now been so largely introduced into England, that they certainly claim attention. As regards their beauty, sport-giving and edible qualities, they rival the sea-trout, while they grow with astonishing rapidity when well furnished with food. They are easily reared, and are certainly a great acquisition. They have not yet had time to become acquainted with the methods of English fly-fishers, and rise freely at any fly and take all the ordinary trout baits. They succeed particularly well in lochs and other enclosed sheets of water. They appear to have migratory tendencies, but it has not yet been definitely ascertained whether this migration is simply in search of food from streams and rivers where they find themselves starved, or whether it is an instinct. A quantity which were placed in the Dove have, to the knowledge of the writer, remained there three years. They have disappeared from many streams.

Rainbow trout.

The grayling (*Salmo thymallus*), which is found in many of the trout streams, is, like the trout, a member of the salmon family. It spawns in the spring, gets rapidly into condition, but is more commonly fished for in autumn than in summer. On the whole, it frequents somewhat quieter waters than the trout. In the chalk streams it is taken by the ordinary dry-fly methods, and elsewhere with both the wet and dry fly. It is less easily alarmed than the trout, and will rise again and again from the bottom, a peculiarity of the fish. Two of the best grayling flies are a very small apple-green dun and the red tag; but a good imitation of any fly on the water will usually take this fish. Many grayling are caught in the north of

Grayling.

England by means of light worm tackle worked with an exceedingly small float and a single shot. This is cast out here and there in rippling streams, the angler striking at the slightest bite. A method which is gradually dying out is the so-called grasshopper, a good-sized hook weighted with lead and the shank bound round with green silk, a straw placed on each side of the bend of the hook, and the point covered with gentles. This arrangement is worked with a sink-and-draw motion, and can hardly be termed a sportsmanlike method, for the grayling is a very sport-giving fish.

Pike, or jack (*Esox lucius*), are usually fished for with a dead or live bait, according to the season of the year and the condition of the water. When the weeds are down, or at any time in such places as weir-pools, a live bait on float tackle is a deadly method, provided the bait can be made to travel, and be brought under the observation of a number of fish. For very small baits a single hook is used, placed through the lip of the bait. For those of medium size, two triangles, placed within about an inch and a half of each other, are preferred. The hook of the upper of these is caught in the back fin of the bait, while the hook of the lower triangle, usually made small for the purpose, and sometimes reversed, is affixed to the bait near the shoulder. This is commonly known as the Jardine tackle. For larger baits the Bickerdyke tackle is one of the best made. This is saddle-back in character, arming both sides of the bait. A single hook is stuck through the back fin and whipped on to the two links of gimp bearing the side hooks, where they join. One of these side triangles hangs down loosely under the back fin, while the other, which is on a longer piece of gimp, is brought up to the shoulder of the bait and held there by means of a reversed hook. Thus, when a pike is struck the tackle is usually pulled away from the bait into the fish's mouth. Live baiting with gorge tackle is quite out of date, snap tackles of the kind described having proved far more effective. Paternostering is another method of pike fishing with live bait much favoured by modern anglers. The pike paternoster consists simply of a two-yard length of stout gut, at the end of which is a half-ounce weight, bullet- or pear-shaped. About two feet from the weight a loop is tied in the gut, and to this is looped a short length of gimp which bears the hook. A long, rather light bamboo rod should be used for swinging out this tackle. The angler fishes entirely by feel; drops his bait in likely places, and, on getting a run, should strike without delay. Spinning is regarded as one of the most sportsmanlike methods of taking pike, and, particularly in lakes, is one of the most successful. The best method of mounting the bait is either on a Bromley-Pennell flight or a Chapman spinner, and the bait may be a small dace, gudgeon, bleak, or sprat, while in very fine, low water a big minnow will sometimes be successful when larger baits fail. Artificial pike baits are legion, but the spoon and phantom still hold their place among the best of them. It is extremely important to have a properly constructed salmon-gut trace, the lead being hung a little below the level of the gut, so that no twisting takes place above it. Immediately below the lead should be a pair of brass swivels, and absolutely none others are required. Such traces are not always kept by tackle dealers, so that the angler frequently has to make them up for himself. The line should be just strong enough to hold the biggest pike likely to be caught, and stouter where many weeds are present than in open water. The rod should be rather stiff, the rings large, and the reel of the Nottingham type with an optional check. With this reel the pike spinner can cast in the Nottingham fashion, or, if he prefers it, in the old-

Pike.

S. I. — 57

fashioned way which is still practised on the Thames and many other rivers. The bait should be spun slowly, and always as near the haunts of the fish as possible, care being taken to spin it deep enough. In big lakes it is usually trailed behind a boat, just in the way that big trout are fished for. Trolling with the dead gorge bait is prohibited on most waters where pike are preserved, as all fish, little and big, caught by this cruel method are destroyed; but a snap-trolling tackle has been devised which gives very good results. It hooks the fish immediately it seizes it. A leaded spike is forced into the bait from head to tail. At the end of the spike is an eye which projects just beyond the tail, and through this the gimp of the hook is threaded, and two triangles lie alongside the bait. The arrangement is shot quickly down into holes between weeds and worked once or twice with a rather sharp sink-and-draw motion. Pike flies are not much used, except in some of the Irish lakes, but pike take them readily enough on those days when they are feeding close to the surface. The haunts of pike, it may be mentioned, are in running water at the beginning of the season, while as the year advances they get into the deeps, hiding away among rushes, reeds, and weed-beds, ever ready to pounce out on any passing fish. In the winter they lie in quieter waters, particularly in eddies; but it may be taken as a pike-fishing maxim that wherever small fish abound, there will the pike be found.

Except for the fact that tackle has been much improved, our knowledge and methods of capturing coarse-fish by what is commonly known as bottom-fishing have The minor coarse-fish. not much advanced during the past half-century; but if one fact concerning these fish has become more strongly emphasized than others, it is that to make a handsome creel of barbel (*Barbus vulgaris*), tench (*Tinca vulgaris*), bream (*Abramis brama*), or carp (*Cyprinus carpio*), it is necessary to ground-bait very heavily in advance of the day's sport. The best ground-bait consists of worms, and the best worms come from Nottingham. There seems something peculiar about the soil of that locality which makes the worms specially attractive to the fish. When fishing a baited hole it is good policy to allow the worm and the shot of the float-tackle to lie on the bottom, or a very light leger may be used with or without a float. Worms nowadays are not usually crowded on to a hook, but quite a small hook is used which is merely caught in the tail, head, or middle of the worm. The bait is thus rendered much more attractive than it would otherwise be, and the fish care little for the visible hook. Success very largely depends on keeping quiet, and, so far as possible, out of sight of the fish. Chub (*Leuciscus cephalus*) may be fished for in many ways; but the Nottingham method, by means of which float-tackle is let down to a swim perhaps 20 yards distant, is one of the most deadly, and has become a great favourite with the modern angler. The line used is exceedingly fine, and the operation a very artistic one. The chub, as is well known, also rises to a fly, and may be caught by various baits, such as frogs, slugs, gentles, cockchafers, &c., cast under the boughs by means of a powerful fly-rod. In fishing for roach (*Leuciscus rutilus*) there has been practically no advance in our knowledge of late years. Tackle-makers provide us with finer gut and better hooks, while the roach bite as shyly as ever. For dace (*Leuciscus vulgaris*), however, and sometimes for roach, it has become quite a common practice in some of the larger rivers to rake the bottom behind the punt before commencing to fish. This not only thickens the water slightly, which usually brings fish up into the swim, but also dislodges a quantity of minute fish food which serves as a natural ground-bait. Dace, it has been found, rise well to the dry fly, when rising at all, and may be caught on an absolutely placid surface by this

method when the wet fly is useless. (See also SEA-FISHING.)

Angola, the general name of the Portuguese possessions on the west coast of Africa lying south of the equator, and embracing Angola proper, which stretches from the mouth of the Cougo to the mouth of the Cunene, and the enclave of Cabinda, immediately north of the Congo. Its boundaries are:—On the N., French Congo and the Congo Free State; on the E., the latter and British South Africa; on the S., German South-West Africa; and on the W., the Atlantic. Area, 484,370 square miles; population, estimated at 4,200,000. It embraces part or whole of the basins of the Congo, Kwanza, and Cunene (flowing west), and of the Kubango and Zambezi (flowing east). Of these streams the Congo and Kwanza alone are navigable at their mouths. The coast-line, partly low, partly broken by rocky promontories, possesses the ports of Loanda, Lobito, Benguela, Mossamedes, Porto Alexandre, and Bahia dos Tigres. There are various mountain chains and tablelands running generally parallel to the coast, as Tala Mugongo (4400 feet), Chella and Vis-sécua (5250 to 6500 feet). In the region of Bailundo are the highest points of the province, viz., Lovili (7780 feet), in 12° 5' S. lat., and Mt. Elonga (7550 feet). South of the Kwanza is the volcanic Mt. Caculo-Cabaza (3300 feet).

With the exception of the district of Mossamedes, the coast districts (the palm country) are unsuited to Europeans. On the interior plateau, above 3300 feet, the temperature and rainfall, together with malaria, decrease southwards as far as the lower course of the Cunene. The mean annual temperature at São Salvador do Congo is 72°·5 Fahr.; at Loanda, 74°·3; and at Caconda, 67°·2. The climate is greatly influenced by the prevailing winds, which are west, south-west, and S.S.W. Two seasons are distinguished—the cool, from June to September; and the rainy, from October to May. The heaviest rainfall occurs in April, and is accompanied by violent storms. The minerals comprise copper at Bembe, on the M'Brije and the Cuvo; iron, at Ociras (on the Incalla) and in Bailundo; petroleum in Dande and Quinzão; gold in Lombije and Cassinga; and mineral salt at Quissama. Behind a region of intermingled grassy plains and palms (especially the Guinea palm, *Elaeis guineensis*) follows a region of savannahs proper and low hills with scanty vegetation. In the south this latter region merges into a barren sandy desert, with *Welwitschia mirabilis* and *Bauhinia*. Amongst the cultivated products are the sugar-cane, cotton tree, coffee, and tobacco; and the exports include coffee, india-rubber, wax, vegetable oils, cocoa-nuts, brandy, cotton, and ivory. In 1896 the coffee crop weighed 4907 tons, and was valued at £329,550, as compared with 1142 tons in 1870; and in the same year the india-rubber crop weighed 2245 tons, valued at £525,550. The yield of wax was valued at £68,450. Industry is not greatly developed; but distilling, and the manufacture of tobacco, bricks, and tiles, and cottons, and the salting of fish are carried on. In 1896 the exports reached a total value of £1,025,100; and to this must be added £222,250, as the annual average exportation of the Congo district, or in all £1,247,350. In the same year the imports totalled £766,700, the principal item being textiles (£368,900, of which £174,900, or nearly one-half, came from Lisbon). In 1899 the exports reached £1,768,554, and the imports totalled £1,536,049. The total commerce of the province has nearly quadrupled since 1870, i.e., it has increased from £227,800 (1870) to £3,304,603 (1899). In 1897 the ports of the province were entered and cleared by an

aggregate of 3384 vessels of 1,123,289 tons. There is a railway from Loanda to Ambaca; including this line, and others building, the province possesses 200 miles of railway. There are 670 miles of telegraphs. The native population consists of Bushmen, Jagas or Iaccas (Bangala), and Bantus. The province is divided into five districts—Congo, Loanda, Benguela, Mossamedes, and Lunda. The province, the capital of which is Loanda (or Luanda), is administered by a governor-general. It forms a bishopric of the ecclesiastical province of Lisbon.

See E. DE VASCONCELLOS. *As Colonias Portuguesas*. Lisbon, 1896-97.

(E. DE V.)

Ángora, (1) a Turkish viláyet in north-central Asia Minor, which includes most of the ancient Galatia. It is an agricultural country, depending for its prosperity on its grain and the mohair obtained from the Ángora goats—average annual clip 3,300,000 lb. The only important industry is carpet-weaving at Kir-shehr and Kaisarieh. There are mines of silver, copper, lignite, and salt, and many hot springs, including some of great repute medicinally. Average annual exports, 1896-98, £920,762; imports, £411,836. Population, 900,000 (Moslems, 765,000; Christians, 135,000). (2) The chief town of the viláyet, classical *Ancyra*, Turkish *Enguri*, situated on the left bank of the Enguri Su, a tributary of the Sakaríá, on the slopes of a rocky hill which rises 500 feet above the plain, and is crowned by the ruins of the old citadel.

Christianity was probably introduced at an early date, but there is no evidence that the Ancyran church was founded by St Paul, or that he ever visited North Galatia. The town was captured by the Persians, the Arabs, the Seljúk Turks, and the Crusaders before it passed to the Osmanli Turks. In 1832 it was taken by the Egyptians. Ángora is connected with Constantinople by railway, and exports mohair, grain, and yellow berries. Mohair cloth is manufactured, and the town is noted for its honey and fruit. From 1639 to 1768 there was an agency of the Levant Company at Ángora, and there is now a British consul. Population, 30,000 (Moslems, 18,000; Christians, chiefly Roman Catholic Armenians, 11,500; Jews, 500).

(C. W. W.)

Angostura. See CIUDAD BOLIVAR.

Angoulême, chief town of the department of Charente, France, 277 miles S.S.W. of Paris, on the railway from Paris to Bordeaux. Seven suburbs surround the town—Honmeau, Saint Ausonne, St Martin, St Cybard, la Bussatte, les Béziers, and St Roch. In addition to other industries it has manufactures of boots and shoes and gloves, wire drawing and rolling mills, and copper founding. Great commerce is carried on in wine, brandy, and paper, and the "pierres d'Angoulême" quarried in the neighbourhood. Population (1881), 25,750; (1891), 28,515; (1896), 30,616; (1901), 37,650.

Anguilla, or SNAKE, a small island now included in the Presidency of St Kitts-Nevis in the British colony of the Leeward Islands. The destruction of trees by charcoal burners has resulted in the almost complete deforestation of the island. Nearly all the land is in the hands of peasant proprietors, who cultivate sweet potatoes, peas, beans, corn, &c., and rear sheep and goats. Salt is still exported. The population in 1891 amounted to 3699 (123 white, 757 coloured, 2819 negroes).

Anhalt, a duchy of Germany, situated on the Elbe and Saale, and almost surrounded by the Prussian province of Saxony. Agriculture supports some 71,170 of the population, *i.e.*, 24 per cent. of the whole. The principal crops grown are beetroot (for sugar) and potatoes; then come hay, rye, barley, wheat, oats, and tobacco. In 1897 there were in the duchy 18,515 horses, 67,100 cattle, 90,815 pigs, and 91,815 sheep. In 1895, out of a total of 32,280 farms, no less than 22,192, or 68·7 per cent., were less than 2½ acres in area, 7530 between 2½ and 25 acres, 2393 between 25 and 250 acres, and only 165 more than 250 acres. In 1898-99 the sugar refineries produced

83,718 tons of sugar, the breweries 10,472,000 gallons of beer, and the distilleries (1897) 763,000 gallons of pure alcohol. In 1897 the mines produced 1,219,704 tons of lignite, valued at £169,500; 208,664 tons of coal, valued at £42,350; and 44,712 tons of chloride of potassium, valued at £339,100. The population was 232,592 in 1880, 271,963 in 1890, and 316,085 in 1900, of whom 155,185 were males and 160,900 females. All the population, except (1895) 8639 Roman Catholics and 1611 Jews, were members of the Reformed church. In the period 1891-98 inclusive, 101 persons on an average emigrated every year. In the year 1900-1901 the revenue and expenditure balanced at £1,384,823. The public debt amounted in 1899 to £9375, and the state contribution to the empire in 1900 to £127,710.

Ani, an Armenian city of importance in the Middle Ages, now in Russian territory, situated between the Arpa Chai, *Harpasus*, and a deep ravine. In the 9th century it became the capital of the Bagratid kings of Armenia, and when yielded to the Byzantine emperor, 1046, it was a populous city. Soon afterwards it was taken by the Seljúk Turks, and its ruin was completed by the Mongols in the 13th century. Its remains are of great interest, especially those of its churches, which throw much light on the Church architecture of Armenia.

Aniches, an industrial town of France, department of Nord, in the arrondissement of Douai, 12 miles S. by E. of Lille, on railway from Cambrai to Valenciennes. It has rich coal mines and is the seat of one of the most important glass-works in France. Population (1881), 4967; (1891), 6296; (1896), 6437, (comm.) 6924.

Animal Heat. See PHYSIOLOGY.

Anjer, formerly a seaport town on the strait of Sunda, Java, 60 miles W. of Batavia. It was destroyed by the inundation caused by the eruption of Krakatao in August 1883. The telegraph cable between Java and Sumatra terminates at Anjer Kidoel, or New Anjer, 3 miles south of the old site.

Anklam, a town of Prussia, province Pomerania, near the mouth of the river Peene, 53 miles N.W. from Stettin by the railway to Stralsund. The church of St Mary (12th century) has a new tower 335 ft. high. There is here a military school. The industries consist of iron-foundries and factories for sugar and soap. Population (1885), 12,786; (1895), 13,560; (1900), 14,602.

Ankober. See ABYSSINIA.

Annaberg, a town of Germany, Saxony, 6 miles from the frontier of Bohemia, 18½ miles S. by E. of Chemnitz by rail. It has an industrial female school, besides schools for lace, agriculture, commerce, and music. The mining industry has greatly declined. Population (1890), 14,960; (1900), 15,957.

Annam. See TONGKING, COCHIN-CHINA, and INDO-CHINA.

Annan, a royal and parliamentary burgh (Dumfries group), and port of Dumfriesshire, Scotland, standing on the east bank of the river Annan, 93¼ miles S.S.E. of Glasgow by rail. A harbour trust was constituted in 1897, and the harbour accommodation has been improved. The town hall has been rebuilt. Among the industries are sandstone quarrying, cotton manufacture, distilling, boat-building, and nursery gardening. Large marine engineering works have been established in the vicinity. Population of town in 1891, 4860; in 1901, 5804.

Annapolis, a city and seaport of Maryland, U.S.A.,

the capital of the state and of Anne Arundel county. It is connected by rail with Washington and Baltimore. The U.S. Naval Academy buildings were being rebuilt in 1901, the improvements consisting of Cadets' quarters, armoury, boat-house, and a new sea-wall, the whole estimated to cost \$8,000,000, the sum authorized by Congress. In 1900 there were 280 cadets at the Academy. Population (1880), 6642; (1890), 7604; (1900), 8402.

Ann Arbor, a city of Michigan, U.S.A., the capital of Washtenaw county. It is situated in the south-eastern part of the lower peninsula, at an altitude of 771 feet. It is divided into six wards, and is entered by two railways, the Ann Arbor and the Michigan Central. It is a university town, with little in the way of manufactures or commerce. Population (1880), 8061; (1890), 9431; (1900), 14,509.

Anney, chief town of the department of Haute Savoie, France, 401 miles S.E. of Paris, on railway from Aix-les-Bains to Geneva, situated at the north end of Lake Anney, partly on small islands formed by three canals known as the *Thioua*. Its library, noteworthy as being the oldest in Savoie, contains 12,000 volumes, and there is a fine public garden with a statue of Berthollet, a native of this place. Its manufactures, less important than formerly, include paper and felt hats. Population (1881), 9144; (1896), 9436 (comm.), 10,009; (1901), 13,611.

Annelida is a term now seldom used in modern zoology. In 1875, when the article under that name appeared in the ninth edition of this work, it represented a class of organisms of which even at that date our knowledge had so far advanced as to make it impracticable to give a satisfactorily sharp-cut definition of the term. It then included the following orders:—

- i. POLYCHÆTA (marine worms).
- ii. OLIGOCHÆTA (land and fresh-water worms).
- iii. ONYCHOPHORA (Peripatus).
- iv. DISCOPHORA (leeches).
- v. GEPHYREA.

These have now been redistributed, and the following table represents a widely accepted view of their classification, and also shows the headings under which reference will be found in the *Ency. Brit.* (ninth edition or Supplement):—

Classes and Orders.	Articles.
i. CHÆTOPODA—	} WORM.
a. Polychæta.	
b. Archiannelida.	
c. Myzostomida.	
d. Oligochæta.	} ECHIUROIDEA.
ii. ECHIUROIDEA = GEPHYREA } ARMATA.	
iii. HIRUDINEA = DISCOPHORA.	LEECH.
iv. SIPUNCULOIDEA } GEPHYREA }	} SIPUNCULOIDEA.
v. PRIAPULOIDEA } INERMIA. }	
vi. ONYCHOPHORA = PROTACHEATA.	

The first three of these six classes have been shown on anatomical and embryological grounds to have considerable affinity to one another, and are generally admitted to have been derived from a common ancestor of marine habit and chætopodan type—chætopodan in its segmentation, in the possession of a true excretory cœlom and of setæ (chætæ) formed in ectodermal sacs, and in certain definite characters of the nervous and circulatory systems. The second two groups, which are now placed apart from the Echiuroidea, with which they were formerly united as Gephyrea, may prove to be less closely allied to one another; the affinities of Sipunculoidea are perhaps to be sought with Phoronis and the Hemichorda. As to the

position of Peripatus in the animal kingdom, in spite of most complete studies of the anatomy and embryology of numerous species, no general agreement can be said to have been reached by zoologists; its affinities seem to point on the one hand to a chætopodan origin, on the other to relationship with Tracheata (see ARTHROPODA, PERIPATUS).

Anniston, a city of Calhoun county, Alabama, U.S.A., situated in 33° 39' N. lat. and 85° 50' W. long., at an altitude of 693 feet. For a time it grew rapidly as a centre of iron manufacture, in which it is favoured by having ore, coal, and limestone in close proximity. It has several blast furnaces and rolling mills, besides numerous other establishments for the manufacture of iron and steel. It has two railways, the Southern and the Louisville and Nashville. Population (1880), 942; (1890), 9998; (1900), 9695.

Annuities, Terminable (BRITISH GOVERNMENT).—Terminable Annuities were introduced into, and have been employed in, the system of British public finance as a means of reducing the National Debt. This result is attained by substituting for a perpetual annual charge (or one lasting until the capital which it represents can be paid off *en bloc*), an annual charge of a larger amount, but lasting for a shorter term. The latter is so calculated as to pay off, during its existence, the capital which it replaces, with interest at an assumed or agreed rate, and under specified conditions. The theoretical bases of such calculations are explained in the article "ANNUITIES" in the ninth edition of this work. The practical effect of the substitution of a terminable annuity for an obligation of longer currency is to bind the present generation of citizens to increase its own obligations in the present and near future in order to diminish those of its successors. This end might be attained in other ways; for instance, by setting aside out of revenue a fixed annual sum for the purchase and cancellation of debt (Pitt's method, in intention), or by fixing the annual debt charge at a figure sufficient to provide a margin for reduction of the principal of the debt beyond the amount required for interest (Sir Stafford Northcote's method), or by providing an annual surplus of revenue over expenditure (the "old Sinking Fund"), available for the same purpose. All these methods have been tried in the course of British financial history, and the second and third of them are still employed; but on the whole the method of terminable annuities has been the one preferred by Chancellors of the Exchequer and by Parliament.

Terminable annuities, as employed by the British Government, fall under two heads:—(a) Those issued to or held by private persons; (b) those held by Government departments, or by funds under Government control. The important difference between these two classes is that an annuity under (a), once created, cannot be modified except with the holder's consent, *i.e.*, is practically unalterable without a breach of public faith; whereas an annuity under (b) can, if necessary, be altered by inter-departmental arrangement under the authority of Parliament. Thus annuities of class (a) fulfil most perfectly the object of the system as explained above; while those of class (b) have the advantage that in times of emergency their operation can be suspended without any inconvenience or breach of faith, with the result that the resources of Government can on such occasions be materially increased, apart from any additional taxation. For this purpose it is only necessary to retain as a charge on the income of the year a sum equal to the (smaller) perpetual charge which was originally replaced by the (larger) terminable charge, whereupon the difference between the two amounts is temporarily released, while ultimately the increased charge

is extended for a period equal to that for which it is suspended. The terminable annuities of class (b) were dealt with in this manner in 1885-86 and in 1900-1901.

Annuities of class (a) were first instituted in 1808, but are at present mainly regulated by an Act of 1829. They may be granted either for a specified life, or two lives, or for an arbitrary term of years; and the consideration for them may take the form either of cash or of Government stock, the latter being cancelled when the annuity is set up. The total amount of permanent debt cancelled by these means from 1808 to 31st March 1890 was about 77½ millions: the charge on the Exchequer for such annuities in the year 1898-99 was £1,284,000; the amount of stock and cash applied in the same year to the purchase of fresh annuities was £1,119,000; and the annuities issued are valued at about ten years' purchase. These figures consist almost wholly of annuities for lives. It may be inferred from the published returns that the net reduction of debt since 1890 by this channel has amounted on the average to nearly £900,000 a year, so that the total reduction of debt by this means, up to 1900, must have been about 86 millions.

Annuities (b) held by Government departments date from 1863. They have been created in exchange for permanent debt surrendered for cancellation, the principal operations having been effected in 1863, 1867, 1870, 1874, 1883, and 1899. The amount so cancelled up to 1883 inclusive was £118,242,000, and as the capital value of the terminable annuities of this class outstanding on 31st March 1899 was £22,765,000, it may be concluded that nearly 100 millions of permanent debt will have been extinguished by this method at the end of the century. The amount of permanent debt cancelled and converted into terminable annuities in 1899 was twenty-eight millions.

Annuities of this class (b) do not affect the public at all, except of course in their effect on the market for Government securities. They are merely financial operations between the Government, in its capacity as the banker of savings banks and other funds, and itself, in the capacity of custodian of the national finances. Savings bank depositors are not concerned with the manner in which Government invests their money, their rights being confined to the receipt of interest and the repayment of deposits upon specified conditions. The case is, however, different as regards forty millions of consols (included in the above figures), belonging to suitors in Chancery, which were cancelled and replaced by a terminable annuity in 1883. As the liability to the suitors in that case was for a specified amount of stock, special arrangements were made to ensure the ultimate replacement of the precise amount of stock cancelled.

Altogether, therefore, it appears that during the 19th century over two hundred millions of the permanent national debt of the United Kingdom were cancelled or put in course of cancellation by means of terminable annuities.

See *Report of the Commissioners for the Reduction of the National Debt*, 1891, Parliamentary Paper, C. 6539. (S. E. S.-R.)

Ansbach, a town of Bavaria, Germany, district Middle Franconia, 27 miles by rail S.W. from Nuremberg. There are a new municipal museum and a special technical school. Ansbach possesses monuments to the native poets Platen and Uz, and to Casper Hauser, the "wild boy," who died here in 1833. Population (1885), 13,935; (1895), 15,883; (1900), 17,555.

Ansonia, a town and city of New Haven county, Connecticut, U.S.A. It is situated on the Naugatuck, just above its junction with the Housatonic, in the

southern part of the state, 12 miles north-west of New Haven. It is divided into five wards, and its plan is quite irregular. The New York, New Haven, and Hartford railway furnishes communication. Its manufactures, depending on the river for water-power, are chiefly in brass and iron. Its clocks have long been well known. Population (1890), 10,342; (1900), 12,681.

Anstruther, Easter and Wester, a fishing town and railway station of Fifeshire, Scotland, in the St Andrews group of parliamentary burghs, 9 miles S.S.E. of St Andrews. The harbour was completed in 1877 at a cost of over £80,000. An endowed higher-class school was opened in 1886. Population, 2000.

Antalo. See **ABYSSINIA**.

Antanànarivo, the capital of Madagascar, situated centrally as regards the length of the island, but only about 90 miles distant from the eastern coast, in 18° 55' S. lat. and 47° 31' E. long. The city occupies a commanding position, being chiefly built on the summit and slopes of a long and narrow rocky ridge, which extends north and south for about two and a half miles, and rises at its highest point to nearly 700 feet above the extensive rice-plain to the west, which is itself 4000 feet above sea-level. For long only the principal village of the Hova chiefs, Antanànarivo advanced in importance as those chiefs made themselves sovereigns of Madagascar until it became a town of some 80,000 inhabitants. Until 1869 all buildings within the city proper were of wood or rush, but even then it possessed several timber palaces of considerable size, the largest being 120 feet high. Since the introduction of stone and brick for building, the whole city has been rebuilt, and it now contains numerous structures of some architectural pretensions, the royal palaces, the houses of the prime minister and nobles, the French residency, the Anglican and Roman Catholic cathedrals, several stone churches (as well as others of brick), colleges, schools, hospitals, courts of justice and other Government buildings, and hundreds of good dwelling-houses. Since the French conquest in 1895 good roads have been constructed throughout the city, and the central space, called "Andohàlo," has become a handsome *place*, with walks and terraces, flower-beds, and trees. Water is obtained from several springs at the foot of the hill, but the supply is scanty. The population is now about 60,000, but varies somewhat at different periods. The city is guarded by two forts built on hills to the east and south-west respectively. (J. S. R.)*

Antarctic. See **POLAR REGIONS**.

Antelope.—Our knowledge of the group of ruminants, commonly known as antelopes, has greatly increased of late years, and a new treatment of the subject is now necessary. There is some uncertainty as to the origin of the name, but it is not improbably derived from *Pantholops*, the old Coptic term for the unicorn. It properly denotes the Indian black buck, which alone constitutes the genus *Antelope*, with the title of *A. cervicapra*, but the term has been extended to embrace a very large group of hollow-horned ruminants, or *Bovidae*, which do not come under the designation of oxen, sheep, or goats—the prong-buck of America (*Antilocapra americana*) being, however, excluded, and forming a family by itself. The group, which scarcely admits of exact definition, is divided into several subfamilies, the majority of which are restricted to Africa (or Africa and Arabia), where more than one hundred different species are known to exist.

The first subfamily (*Bubalinae*) includes the hartebeests (*Bubalis* and *Damaliscus*) and the gnus or wildebeests (*Connochætes*), all of which are large antelopes confined to Africa, with the exception of

one Arabian species. The typical hartebeests (*Bubalis*) are short-haired animals, with high withers, long faces, and sharply bent ridged horns, but in the blebok and its allies (*Damaliscus*) the last three features are less marked. Heavy heads, smooth horns, long manes, and horse-like tails sufficiently characterize the genus. The second subfamily, or *Cephalophinae*, includes small or medium-sized species, represented only by the duikers or "divers" (*Cephalophus*) of Africa, and the four-horned antelope (*Tetraceros*) of India. All have naked muzzles, elongated face-glands or tear-pits, false hoofs, and four mammae, but there are no hair-tufts at the knees. The short and upright horns are generally present in both sexes. A third group, *Oreotraginae*, exclusively African, is represented by a number of small forms, such as the tiny dik-diks (*Madoqua*), oribis (*Oribia*), sunis (*Nesotragus*), steinboks (*Rhaphiceros*), and the active klipspringer (*Oreotragus*). Of much larger size are the African water-bucks and kobs (*Cobus*) and reed-buck (*Cervicapra*), which constitute the subfamily *Cervicaprinae*, and include some of the handsomest of all antelopes, among them being the black *Cobus maria* and *C. leucotis* of the swamps of the White Nile. The muzzle is naked and the females are hornless. The Vaal rhebok (*Pelea*) likewise belongs to this group. In the typical subfamily or *Antilopinae*, in which the females are also generally without horns, are included the Indian black buck (*Antelope*), the graceful African pala (*Epyceros*), the puffy-nosed saiga (*Saiga*) of Central Asia, the long-horned chiru (*Pantholops*) of Tibet, the South African spring-buck (*Antidorcas*), the numerous and widely-spread group of gazelles (*Gazella*), and the dibatag (*Ammodorcas*), the long-necked gerenuk (*Lithocranius*), and the tiny beira (*Dorcotragus*) of Somaliland and East Africa. Widely

different from all the foregoing is the African group of *Hippotraginae*, all the members of which are of large size and have long horns in both sexes. Among these are the sable and the roan antelope (*Hippotragus*), with sabre-like horns, the straight-horned gemsbok and beisa (*Oryx*), and the long-haired and spiral-horned addax of the Sahara. The last group of what may be termed true antelopes is the *Tragelaphinae*, in which the size is mostly large, and the spirally twisted horns are, excepting in the elands, restricted to the males. The sole non-African representative of the group is the Indian nilgai (*Boselaphus*), in which the horns are much shorter than in the rest. The African forms include the beautiful bush-bucks or harnessed antelopes (*Tragelaphus*), in which the females are often more brightly coloured than the males, the striped kudus (*Strepsiceros*), and the elands (*Taurotragus*), which are the largest of all antelopes. The remaining group (*Rupicaprinae*), which indicates a transition towards the goats, is represented by the chamois (*Rupicapra*), of the mountains of Southern Europe, the goral (*Urotragus*), and serows (*Nemorhædus*) of Eastern Asia, the takin (*Budorcas*) of the Mishmi Hills and Tibet, and the so-called Rocky Mountain goat (*Oreamnus*) of North America, which is the sole transatlantic representative of the antelopes, if indeed it be entitled to be called an antelope at all. (R. L.*)

Antequera, a city of Spain, province of Malaga, 28 miles N. of Malaga. Since 1890 a thriving industry has been created by beetroot and cane-sugar factories, employing several thousand hands. Population, 24,387.

ANTHOZOA.

ALTHOUGH corals have been familiar objects since the days of antiquity, and the variety known as the precious red coral has been for a long time an article of commerce in the Mediterranean, it was only in the 18th century that their true nature and structure came to be understood. By the ancients and the earlier naturalists of the Christian era they were regarded either as petrifications or as plants, and many supposed that they occupied a position midway between minerals and plants. The discovery of the animal nature of red coral is due to J. A. de Peyssonel, a native of Marseilles, who obtained living specimens from the coral fishers on the coast of Barbary and kept them alive in aquaria. He was thus able to see that the so-called "flowers of coral" were in fact nothing else than minute polyps resembling sea-anemones. His discovery, made in 1727, was rejected by the Academy of Sciences of France, but eventually found acceptance at the hands of the Royal Society of London, and was published by that body in 1751. The structure and classification of polyps, however, were at that time very imperfectly understood, and it was fully a century before the true anatomical characters and systematic position of corals were placed on a secure basis.

The hard calcareous substance to which the name coral is applied is the supporting skeleton of certain members of the *Anthozoa*, one of the classes of the phylum *Cœlentera*. The most familiar Anthozoan is the common sea-anemone, *Actinia equina*, L., and it will serve, although it does not form a skeleton or *corallum*, as a good example of the structure of a typical Anthozoan polyp or zooid. The individual animal or zooid of *Actinia equina* has the form of a column fixed by one extremity, called the *base*, to a rock or other object, and bearing at the opposite extremity a crown of *tentacles*. The tentacles surround an area known as the *peristome*, in the middle of which there is an elongated mouth-opening surrounded by tumid lips. The mouth does not open directly into the general cavity of the body, as is the case in a hydrozoan polyp, but into a short tube called the *stomodæum*, which in its turn opens below into the general body-cavity or *cœlenteron*. In *Actinia* and its allies, and most generally, though not invariably, in *Anthozoa*, the stomodæum is not circular but is compressed from side to side so as to be oval or slit-

like in transverse section. At each end of the oval there is a groove lined by specially long vibratile cilia. These grooves are known as the *sulcus* and *sulculus*, and will be more particularly described hereafter. The elongation of the mouth and stomodæum confer a bilateral symmetry on the body of the zooid, which is extended to other organs of the body. In *Actinia*, as in all Anthozoan zooids, the *cœlenteron* is not a simple cavity, as in a *Hydroid*, but is divided by a number of radial folds or curtains of soft tissue into a corresponding number of radial chambers. These radial folds are known as *mesenteries*, and their position and relations may be understood by reference to Figs. 1 and 2. Each mesentery is attached by its upper margin to the peristome, by its outer margin to the body-wall, and by its lower margin to the basal disc. A certain number of mesenteries, known as complete mesenteries, are attached by the upper parts of their internal margins to the stomodæum, but below this level their edges hang free in the *cœlenteron*. Other mesenteries, called incomplete, are not attached to the stomodæum, and their internal margins are free from the peristome to the basal disc. The lower part of the free edge of every mesentery, whether complete or incomplete, is thrown into numerous puckers or folds, and is furnished with a glandular thickening known as a *mesenterial filament*. The reproductive organs or gonads are borne on the mesenteries, the germinal cells being derived from the inner layer or endoderm.

FIG. 1.—Diagrammatic longitudinal section of an Anthozoan zooid. *m*, mesentery; *t*, tentacles; *st*, stomodæum; *sc*, sulcus; *r*, Rotteken's muscle; *s*, stoma; *lm*, longitudinal muscle; *d*, diagonal muscle; *go*, gonads.

In common with all *Cœlenterate* animals, the walls of

the columnar body and also the tentacles and peristome of Actinia are composed of three layers of tissue. The external layer, or *ectoderm*, is made up of cells, and contains also muscular and nervous elements. The preponderating elements of the

FIG. 2.—1, Portion of epithelium from the tentacles of an Actinia, showing three supporting cells and one sense cell (sc). 2, A onidoblast with enclosed nematocyst from the same specimen. 3 and 4, Two forms of gland cell from the stomodæum. 5a, 5b, Epithelio-muscular cells from the tentacle in different states of contraction. 5c, An epithelio-muscular cell from the endoderm, containing a symbiotic zooxanthella. 6, A ganglion cell from the ectoderm of the peristome. (After O. and R. Hertwig.)

crowded with yellow spherical bodies, which are unicellular plants or Algæ, living symbiotically in the tissues of the zooid. The endoderm contains in

addition gland cells and nervous elements. The middle layer or mesoglœa is not originally a cellular layer, but a gelatinoid structureless substance, secreted by the two cellular layers. In the course of development, however, cells from the ectoderm and endoderm may migrate into it. In *Actinia equina* the mesoglœa consists of fine fibres imbedded in a homogeneous matrix, and between the fibres are minute branched or spindle-shaped cells. For further details of the structure of Actinians, the reader should consult the work of O. and R. Hertwig (9).

The Anthozoa are divisible into two sub-classes, sharply marked off from one another by definite anatomical characters. These are the ALCYONARIA and the ZOANTHARIA.

FIG. 3.—An expanded Alcyonarian zooid, showing the mouth surrounded by eight pinnate tentacles. st, stomodæum in the centre of the transparent body; m, mesenteries; asm, assular mesenteries; B, spicules, enlarged.

To the first-named belong the precious red coral and its allies, the sea-fans of Gorgoniæ; to the second belong the white or Madreporarian corals.

Alcyonaria.—In this sub-class the zooid (Fig. 3) has very constant anatomical characters, differing in some important respects from the Actinian zooid, which has been taken as a type. There is only one ciliated groove, the sulcus, in the stomodæum. There are always eight tentacles, which are hollow and fringed on their sides, with hollow projections or pinnæ; and always eight mesenteries, all of which are complete, *i.e.*, inserted on the stomodæum. The mesenteries are provided with well-developed longitudinal retractor muscles, supported on longitudinal folds or plaits of the mesoglœa, so that in cross-section they have a branched appearance. These *muscle-banners*, as they are called, have a highly characteristic arrangement; they are all situated on those faces of the mesenteries which look towards the sulcus (Fig. 4). Each mesentery has a filament; but two of them, namely, the pair farthest from the sulcus, are longer than the rest, and have a different form of filament. It has been shown that these assular filaments are derived from the ectoderm, the remainder from the endoderm. The only exceptions to this structure are found in the arrested or modified zooids, which occur in many of the colonial Alcyonaria. In these the tentacles are stunted or suppressed and the mesenteries are ill-developed, but the sulcus is unusually large and has long cilia. Such modified zooids are called siphonozooids, their function being to drive currents of fluids through the canal-systems of the colonies to which they belong. With very few exceptions a calcareous skeleton is present in all Alcyonaria; it usually consists of spicules of carbonate of lime, each spicule being formed within an ectodermic cell (Fig. 3, B). Most commonly the spicule-forming cells pass out of the ectoderm and are imbedded in the mesoglœa, where they may remain separate from one another or may be fused together to form a strong mass. In addition to the spicular skeleton an organic horny skeleton is frequently present, either in the form of a horny external investment (Cornularia), or an internal axis (Gorgonia), or it may form a matrix in which spicules are imbedded (Kercoïdes, Melitodes).

FIG. 4.—Transverse section of an Alcyonarian zooid. mm, mesenteries; mb, muscle banners; sc, sulcus; st, stomodæum.

Nearly all the Alcyonaria are colonial. Four solitary species have been described, *viz.*, *Haima funebris* and *H. hyalina*, *Hartea elegans*, and *Monoxenia Darwinii*; but it is doubtful whether these are not the young forms of colonies. For the present the solitary forms may be placed in a grade, *Protalcyonacea*; and the colonial forms may be grouped in another grade, *Synalcyonacea*. Every Alcyonarian colony is developed by budding from a single parent zooid. The buds are not direct outgrowths of the body-wall, but are formed on the courses of hollow outgrowths of the base or body-wall, called *solenia*. These form a more or less complicated canal system, lined by endoderm, and communicating with the cavities of the zooids. The most simple form of budding is found in the genus *Cornularia*, in which the mother zooid gives off from its base one or more simple radiceform outgrowths. Each outgrowth contains a single tube or solenium, and at a longer or shorter distance from the mother zooid a daughter zooid is formed as a bud. This gives off new outgrowths, and these, branching and anastomosing with one another, may form a network, adhering to stones, corals, or other objects, from which zooids arise at intervals. In *Clavularia* and its allies each outgrowth contains several solenia, and the outgrowths may take the form of flat expansions, composed of a number of solenial tubes felted together to form a lamellar surface of attachment. Such outgrowths are called *stolons*, and a stolon may be simple, *i.e.*, contain only one solenium, as in *Cornularia*, or may be complex and built up of many solenia, as in *Clavularia*. Further complications arise when the lower walls of the mother zooid become thickened and interpenetrated with solenia, from which buds are developed, so that lobose, tufted, or branched colonies are formed. The chief orders of the Syn-

alcyonacea are founded upon the different architectural features of colonies produced by different modes of budding. We recognize six orders—the STOLONIFERA, ALCYONACEA, PSEUDAXONIA, AXIFERA, STELECHOTOKEA, and CŒNOTHECALIA.

In the order STOLONIFERA the zooids spring at intervals from branching or lamella stolons, and are usually free from one another, except at their bases, but in some cases horizontal solenia arising at various heights from the body-wall may place the more distal

portions of the zooids in communication with one another. In the genus *Tubipora* these horizontal solenia unite to form a series of horizontal platforms (Fig. 5). The order comprises the families *Cornulariidae*, *Syringoporidae*, *Tubiporidae*, and *Favositidae*. In the first-named the zooids are united only by their bases and the skeleton consists of loose spicules. In the *Tubiporidae* the spicules of the proximal part of the body-wall are fused together to form a firm tube, the corallite, into which the distal part of the zooid can be retracted. The corallites are connected at intervals by horizontal platforms containing solenia, and at the level of each platform the cavity of the corallite is divided

Fig. 5.—A, Skeleton of a young colony of *Tubipora purpursea*, st, stolon; p, platform. B, Diagrammatic longitudinal section of a corallite, showing two platforms, p, and simple and cup-shaped tabulae, t. (After Hickson.)

by a transverse calcareous partition, either flat or cup-shaped, called a *tabula*. Formerly all corals in which tabulae are present were classed together as Tabulata, but *Tubipora* is an undoubted Alcyonarian with a lamellar stolon, and the structure of the fossil genus *Syringopora*, which has vertical corallites united by horizontal solenia, clearly shows its affinity to *Tubipora*. The *Favositidae*, a fossil family from the Silurian and Devonian, have a massive corallum composed of numerous polygonal corallites closely packed together. The cavities of adjacent corallites communicate by means of numerous perforations, which appear to represent solenia, and numerous transverse tabulae are also present. In *Favosites hemisphaerica* a number of radial spines, projecting into the cavity of the corallite, give it the appearance of a madreporarian coral.

In the order ALCYONACEA the colony consists of bunches of elongate cylindrical zooids, whose proximal portions are united by solenia and compacted, by fusion of their own walls and those of the solenia, into a fleshy mass called the cœnenchyma. Thus the cœnenchyma forms a stem, sometimes branched, from the surface of which the free portions of the zooids project. The skeleton of the Alcyonacea consists of separate calcareous spicules, which are often, especially in the *Nephthyidae*, so abundant and so closely interlocked as to form a tolerably firm and hard armour. The order comprises the families *Xenidae*, *Alcyonidae*, and *Nephthyidae*. *Alcyonium digitatum*, a pink digitate form popularly known as "dead men's fingers," is common in 10-20 fathoms of water off the English coasts.

In the order PSEUDAXONIA the colonies are upright and branched, consisting of a number of short zooids whose proximal ends are imbedded in a cœnenchyma containing numerous ramifying solenia and spicules. The cœnenchyma is further differentiated into a medullary portion and a cortex. The latter contains the proximal moieties of the zooids and numerous but separate spicules. The medullary portion is densely crowded with spicules of different shape from

Fig. 6.—Portion of a colony of *Corallium rubrum*, showing expanded and contracted zooids. In the lower part of the figure the cortex has been cut away to show the axis, ax, and the longitudinal canals, lc, surrounding it.

those in the cortex, and in some forms the spicules are cemented together to form a hard supporting axis. There are four families of Pseudaxonia—the *Briareidae*, *Sclerogorgiidae*, *Melitodidae*, and *Corallidae*. In the first-named the medulla is penetrated by solenia and forms an indistinct axis; in the remainder the medulla is devoid of solenia, and in the *Melitodidae* and *Corallidae* it forms a dense axis, which in the *Melitodidae* consists of alternate calcareous and horny joints. The precious red coral of commerce, *Corallium rubrum* (Fig. 6), a member of the family *Corallidae*, is found at depths varying from 15 to 120 fathoms in the Mediterranean Sea, chiefly on the African coast. It owes its commercial value to the beauty of its hard red calcareous axis, which in life is covered by a cortex in which the proximal moieties of the zooids are imbedded. *Corallium rubrum* has been the subject of a beautifully-illustrated memoir by de Lacaze Duthiers, which should be consulted for details of anatomy.

The AXIFERA comprises those corals that have a horny or calcified axis, which in position corresponds to the axis of the Pseudaxonia, but, unlike it, is never formed of fused spicules; the most familiar example is the pink sea-fan, *Gorgonia Cavolinii*, which is found in abundance in 10-25 fathoms of water off the English coasts (Fig. 7). In this order the axis is formed as an ingrowth of the ectoderm of the base of the mother zooid of the colony, the cavity of the

Fig. 7.—The sea-fan (*Gorgonia Cavolinii*).

Fig. 8.—A, Colony of *Pennatulula phosphorea* from the metarachidial aspect. p, the peduncle. B, Section of the rachis bearing a single pinna. a, axis; b, metarachidial; c, prorsachidial; d, pararachidial stem canals.

ingrowth being filled by a horny substance secreted by the ectoderm. In *Gorgonia* the axis remains horny throughout life, but in many forms it is further strengthened by a deposit of calcareous matter. In the family *Isidinae* the axis consists of alternate segments of horny and calcareous substance, the latter being amorphous. The order contains six families—the *Dasygorgiidae*, *Isididae*, *Primnoidae*, *Muriceidae*, *Plexauridae*, and *Gorgoniidae*.

In the order STELECHOTOKEA the colony consists of a stem formed by a greatly-elongated mother zooid, and the daughter zooids are borne as lateral buds on the stem. In the section *Asiphonacea* the colonies are upright and branched, springing from membranous or ramifying stolons. They resemble and are closely allied to certain families of the *Cornulariidae*, differing from them only in mode of budding and in the disposition of the daughter zooids round a central, much-elongated mother zooid. The section contains two families, the *Telestidae* and the *Calogorgiidae*. The second section comprises the *Pennatulaceae* or sea-pens,

which are remarkable from the fact that the colony is not fixed by the base to a rock or other object, but is imbedded in sand or mud by the proximal portion of the stem known as the peduncle. In the typical

genus, *Pennatula* (Fig. 8), the colony looks like a feather having a stem, divisible into an upper moiety or rachis, bearing lateral central leaflets (pinnæ), and a lower peduncle, which is sterile and embedded in sand or mud. The stem represents a greatly enlarged and elongated mother zooid. It is divided longitudinally by a partition separating a so-called "ventral" or prorachidial canal from a so-called "dorsal" or metarachidial canal. A rod-like supporting axis of peculiar texture is developed in the longitudinal partition, and a longitudinal canal is hollowed out on either side of the axis in the substance of the longitudinal partition, so that there are four stem-canals in all. The prorachidial and metarachidial aspects of the rachis are sterile, but the sides or pararachides bear numerous daughter zooids of two kinds—(1) fully-formed autozooids, (2) small stunted siphonozooids. The pinnæ are formed by the elongated autozooids, whose proximal portions are fused together to form a leaf-like expansion, from the upper edge of which the distal extremities of the zooids project. The siphonozooids are very numerous and lie between the bases of the pinnæ on the pararachides; they extend also on the prorachidial and metarachidial surfaces. The calcareous skeleton of the Pennatulacea consists of scattered spicules, but in one species, *Protocaulon molle*, spicules are absent. Although of great interest the Pennatulacea do not form an enduring skeleton or "coral," and need not be considered in detail in this place.

The order *CENOTHECALIA* is represented by a single living species, *Heliopora cærulea*, which differs from all recent Alcyonaria in the fact that its skeleton is not composed of spicules, but is formed as a secretion from a layer of cells called calicoblasts, which originate from the ectoderm. The corallum of *Heliopora* is of a blue colour, and has the form of broad, upright, lobed, or digitate masses flattened from side to side. The surfaces are pitted all over with perforations

FIG. 9.—A, Portion of the surface of a colony of *Heliopora cærulea* magnified, showing two calices and the surrounding cœnenchymal tubes. B, Single zooid with the adjacent soft tissues as seen after removal of the skeleton by decalcification. Z', the distal, and Z, the proximal or intracalcular portion of the zooid; ec, ectoderm; ct, cœnenchymal tubes; sp, superficial network of solenia.

of two kinds, viz., larger star-shaped cavities, called *calices*, in which the zooids are lodged, and very numerous smaller round or polygonal apertures, which in life contain as many short unbranched tubes, known as the *cœnenchymal tubes* (Fig. 9, A). The walls of the calices and cœnenchymal tubes are formed of flat plates of calcite, which are so disposed that the walls of one tube enter into the composition of the walls of adjacent tubes, and the walls of the calices are formed by the walls of adjacent cœnenchymal tubes. Thus the architecture of the Helioporida colony differs entirely from such forms as Tubipora or Favosites, in which each corallite has its own distinct and proper wall. The cavities both of the calices and cœnenchymal tubes of *Heliopora* are closed below by horizontal partitions or *tabulæ*, hence the genus was formerly included in the group Tabulata, and was supposed to belong to the madreporarian corals, both because of its lamellar skeleton, which resembles that of a Madrepora, and because each calicle has from twelve to fifteen radial partitions or septa projecting into its cavity. The structure of the zooid of *Heliopora*, however, is that of a typical Alcyonarian, and the septa have only a resemblance to, but no real homology with, the similarly-named structures in madreporarian corals. *Heliopora cærulea* is found between tide-marks on the shore platforms of coral islands. The order was more abundantly represented in Pallæozoic times by the Heliotidæ from the Upper and Lower Silurian and the Devonian, and by the Thecidæ from the Wenlock limestone. In *Heliolites porosus* the colonies had the form of spheroidal masses; the calices were furnished with twelve pseudosepta, and the cœnenchymal tubes were more or less regularly hexagonal.

Zoantharia.—In this sub-class the arrangement of the mesenteries is subject to a great deal of variation, but all the types hitherto observed may be referred to a common plan, illustrated by the living genus *Edwardsia* (Fig. 10, A, B). This is a small solitary Zoantharian which lives embedded in sand. Its body is divisible into three portions, an upper *capitulum* bearing the mouth and tentacles, a median *scapus* covered by a friable cuticle, and a terminal *physa* which is rounded. Both *capitulum* and *physa* can be retracted within the scapus. There are from sixteen to thirty-two simple

tentacles, but only eight mesenteries, all of which are complete. The stomodæum is compressed laterally, and is furnished with two longitudinal grooves, a sulcus and a sulculus. The arrangement of the muscle-banners on the mesenteries is characteristic. On six of the mesenteries the muscle-banners have the same position as in the Alcyonaria, namely, on the sulcar faces; but in the two remaining mesenteries, namely, those which are attached on either side of the sulcus, the muscle-banners are on the opposite or sulcular faces. It is not known whether all the eight mesenteries of *Edwardsia* are developed simultaneously or not, but in the youngest form which has been studied all the eight mesenteries were present, but only two of them, namely the sulco-laterals, bore mesenterial filaments, and so it is presumed that they are the first pair to be developed. In the common sea-anemone, *Actinia equina* (which has already been quoted as a type of Anthozoan structure), the mesenteries are numerous and are arranged in cycles. The mesenteries of the first cycle are complete (i.e., are attached to the stomodæum), are twelve in number, and arranged in couples, distinguishable by the position of the muscle-banners. In the four couples of mesenteries which are attached to the sides of the elongated stomodæum the muscle-banners of each couple are turned towards one another, but in the sulcar and sulcular couples, known as the directive mesenteries, the muscle-banners are on the outer faces of the mesenteries, and so are turned away from one another (see Fig. 10, C). The space enclosed between two mesen-

FIG. 10.—A, *Edwardsia claparedii* (after A. Andres). cap, capitulum; sc, scapus; ph, physa. B, Transverse section of the same, showing the arrangement of the mesenteries. a, sulcus; sl, sulculus. C, Transverse section of *Halcampa*. d, d, directive mesenteries; st, stomodæum.

teries of the same couple is called an *entocœle*; the space enclosed between two mesenteries of adjacent couples is called an *exocœle*. The second cycle of mesenteries consists of six couples, each formed in an exocœle of the primary cycle, and in each couple the muscle-banners are *vis-à-vis*. The third cycle comprises twelve couples, each formed in an exocœle between the primary and secondary couples, and so on, it being a general rule (subject, however, to exceptions) that new mesenterial couples are always formed in the exocœles, and not in the entocœles.

While the mesenterial couples belonging to the second and each successive cycle are formed simultaneously, those of the first cycle are formed in successive pairs, each member of a pair being placed on opposite sides of the stomodæum. Hence the arrangement in six couples is a secondary and not a primary feature. In most Actinians the mesenteries appear in the following order:—At the time when the stomodæum is formed, a single pair of mesenteries, marked I, I in the diagram (Fig. 11, A), makes its appearance, dividing the enteric cavity into a smaller sulcar and a large sulcular chamber. The muscle-banners of this pair are placed on the sulcar faces of the mesenteries. Next, a pair of mesenteries, marked II, II in the diagram, is developed in the sulcular chamber, its muscle-banners facing the same way as those of I, I. The third pair is formed in the sulcar chamber, in close connexion with the sulcus, and in this case the muscle-banners are on the *sulcular* faces. The fourth pair, having its muscle-banners on the sulcar faces, is developed at the opposite extremity of the stomodæum in close connexion with the sulculus. There are now eight mesenteries present, having exactly the same arrangement as in *Edwardsia*. A pause in the development follows, during which no new mesenteries are formed, and then the six-rayed symmetry characteristic of a normal Actinian zooid is completed by the formation of the mesenteries V, V in the lateral chambers, and VI, VI in the sulco-lateral chambers, their muscle-banners being so disposed that they form couples respectively with II, II and I, I. In *Actinia*

equina the Edwardsia stage is arrived at somewhat differently. The mesenteries second in order of formation form the sulcular directives, those fourth in order of formation form with the fifth the sulculo-lateral couples of the adult.

FIG. 11.—A, Diagram showing the sequence of mesenterial development in an Actinian. B, Diagrammatic transverse section of *Gonactinia prolifera*.

As far as the anatomy of the zooid is concerned, the majority of the stony or madreporian corals agree exactly with the soft-bodied Actinians, such as *Actinia equina*, both in the number and arrangement of the adult mesenteries and in the order of development of the first cycle. The few exceptions will be dealt with later, but it may be stated here that even in these the first cycle of six couples of mesenteries is always formed, and in all the cases which have been examined the course of development described above is followed. There are, however, several groups of Zoantharia in which the mesenterial arrangement of the adult differs widely from that just described. But it is possible to refer all these cases with more or less certainty to the Edwardsian type.

The order ZOANTHIDEA comprises a number of soft-bodied Zoantharians generally encrusted with sand. Externally they resemble ordinary sea-anemones, but there is only one ciliated groove, the sulcus, in the stomodæum, and the mesenteries are arranged on a peculiar pattern. The first twelve mesenteries are disposed in couples, and do not differ from those of Actinia except in size. The mesenterial pairs, I, II, and III, are attached to the stomodæum, and are called macromesenteries (Fig. 12, B), but IV,

FIG. 12.—A, Zoanthid colony, showing the expanded zooids. B, Diagram showing the arrangement of mesenteries in a young Zoanthid. C, Diagram showing the arrangement of mesenteries in an adult Zoanthid. 1, 2, 3, 4, Edwardsian mesenteries.

V, and VI are much shorter, and are called micromesenteries. The subsequent development is peculiar to the group. New mesenteries are formed only in the sulco-lateral exocoels. They are formed in couples, each couple consisting of a macromesentery and a micromesentery, disposed so that the former is nearest to the sulcar directives. The derivation of the Zoanthidea from an Edwardsia form is sufficiently obvious.

The order CERANTHIDEA comprises a few soft-bodied Zoantharians with rounded aboral extremities pierced by pores. They have two circlets of tentacles, a labial and a marginal, and there is only one ciliated groove in the stomodæum, which appears to be the sulculus. The mesenteries are numerous, and the longitudinal muscles, though distinguishable, are so feebly developed that there are no muscle-banners. The larval forms of the type genus *Cerianthus* float freely in the sea, and were once considered to belong to a separate genus, *Arachnactis*. In this larva four pairs of mesenteries having the typical Edwardsian arrangement are developed, in the same sequence as in Rhodactis, but the fifth and sixth pairs, instead of forming couples with the first and second, arise in the sulcar chamber, the fifth pair inside the fourth, and the sixth pair inside the fifth. New mesenteries are continually added in the sulcar chamber, the seventh pair within the sixth, the

eighth pair within the seventh, and so on (Fig. 13). In the Cerianthidea, as in the Zoanthidea, much as the adult arrangement of mesenteries differs from that of Actinia, the derivation from an Edwardsia stock is obvious.

FIG. 13.—A, *Cerianthus solitaris* (After A. Andres). B, Transverse section of the stomodæum, showing the sulculus, *sl*, and the arrangement of the mesenteries. C, Oral aspect of *Arachnactis brachiolata*, the larva of *Cerianthus*, with seven tentacles. D, Transverse section of an older larva. The numerals indicate the order of development of the mesenteries.

The order ANTIPATHIDEA is a well-defined group whose affinities are more obscure. The type form, *Antipathes dichotoma* (Fig. 14), forms arborescent colonies consisting of numerous zooids, arranged in a single series along one surface of a branched horny axis. Each zooid has six tentacles; the stomodæum is elongate, but the sulcus and sulculus are very feebly represented. There are ten mesenteries in which the musculature is so little developed as to be almost indistinguishable. The sulcar and sulcular pairs of mesenteries are short, the sulco-lateral and sulculo-lateral pairs are a little longer, but the two transverse are very large and are the only mesenteries which bear gonads. As the development of the Antipathidea is unknown, it is impossible to say what is the

FIG. 14.—A, Portion of a colony of *Antipathes dichotoma*. B, Single zooid and axis of the same magnified. *m*, mouth; *mf*, mesenterial filament; *ax*, axis. C, Transverse section through the oral cone of *Antipathella minor*. *st*, stomodæum; *ov*, ovary.

sequence of the mesenterial development, but in *Leiopathes glaber-rima*, a genus with twelve mesenteries, there are distinct indications of an Edwardsia stage.

There are, in addition to these groups, several genera of Actinians whose mesenterial arrangement differs from the normal type. Of these perhaps the most interesting is *Gonactinia prolifera* (Fig. 11, B), with eight macromesenteries arranged on the Edwardsian plan. Two pairs of micromesenteries form couples with the first and second Edwardsian pairs, and in addition there is a couple of micromesenteries in each of the sulculo-lateral exocoels. Only the first and second pairs of Edwardsian macromesenteries are fertile, i.e., bear gonads.

The remaining forms, the ACTINIIDEA, are divisible into the Malacactiniæ, or soft-bodied sea-anemones, which have already been described sufficiently in the course of this article (pp. 454-5), and the Scleractiniæ (=Madreporaria), or true corals.

All recent corals, as has already been said, conform so closely to the anatomy of normal Actinians that they cannot be classified apart from them, except that they are distinguished by the possession of a calcareous skeleton. This skeleton is largely composed of a number of radiating plates or *septa*, and it differs both in origin and structure from the calcareous skeleton of all Alcyonaria except *Heliopora*. It is formed, not from fused spicules, but as a secretion of a special layer of cells derived from the basal ectoderm, and known as *calicoblasts*. The skeleton or corallum of a typical solitary coral—the common Devonshire cup-coral *Caryophyllia Smithii* (Fig. 15) is a

FIG. 15.—Corallum of *Caryophyllia*; semi-diagrammatic. *th*, theca; *c*, costæ; *sp*, septa; *p*, pali; *col*, columella.

good example—exhibits the following parts:—(1) The *basal plate*, between the zooid and the surface of attachment. (2) The *septa*, radial plates of calcite reaching from the periphery nearly or quite to the centre of the coral-cup or calicle. (3) The *theca* or wall, which in many corals is not an independent structure, but is formed by the conjoined thickened peripheral ends of the septa. (4) The *columella*, a structure which occupies the centre of the calicle, and may arise from the basal plate, when it is called essential, or may be formed by union of trabecular offsets of the septa, when it is called unessential. (5) The *costæ*, longitudinal ribs or rows of spines on the outer surface of the theca. True costæ always correspond to the septa, and are in fact the peripheral edges of the latter. (6) *Epiteca*, an offset of the basal plate which surrounds the base of the theca in a ring-like manner, and in some corals may take the place of a true theca. (7) *Pali*, spinous or blade-like upgrowths from the bottom of the calicle, which project between the inner edges of certain septa and the columella. In addition to these parts the following structures may exist in corals:—*Dissepiments* are oblique calcareous partitions, stretching from septum to septum, and closing the interseptal chambers below. The whole system of dissepiments in any given calicle is often called *endotheca*. *Synapticulæ* are calcareous bars uniting adjacent septa. *Tabulæ* are stout horizontal partitions traversing the centre of the calicle and dividing it into as many superimposed chambers. The septa in recent corals always bear a definite relation to the mesenteries, being found either in every entocœle or in every entocœle and exocœle. Hence in corals in which there is only a single cycle of mesenteries the septa are correspondingly few in number; where several cycles of mesenteries are present the septa are correspond-

ingly numerous. In some cases—e.g., in some species of *Madrepora*—only two septa are fully developed, the remainder being very feebly represented.

Though the corallum appears to lie within the zooid, it is morphologically external to it, as is best shown by its developmental history. The larvæ of corals are free swimming ciliated forms known as planulæ, and they do not acquire a corallum until they fix themselves. A ring-shaped plate of calcite, secreted by the ectoderm, is then formed, lying between the embryo and the surface of attachment. As the mesenteries are formed, the endoderm of the basal disc lying above the basal plate is raised up in the form of radiating folds. There may be six of such folds, one in each entocœle of the primary cycle of mesenteries; or there may be twelve, one in each exocœle and entocœle. The ectoderm beneath each fold becomes detached from the surface of the basal plate, and both it and the mesogloea are folded conformably with the endoderm. The cells forming the limbs of the ectodermic folds secrete nodules of calcite, and these, fusing together, give rise to six (or twelve) vertical radial plates or septa. As growth proceeds new septa are formed simultaneously with the new couples of secondary mesenteries. In some corals, in which all the septa are entocœlic, each new system is embraced by a mesenteric couple; in others, in which the septa are both entocœlic and exocœlic, three septa are formed in every chamber between two primary mesenterial couples, one in the entocœle of the newly-formed mesenterial couple of the secondary cycle, and one in each exocœle between a primary and a secondary couple. These latter are in turn embraced by the couples of the tertiary cycle of mesenteries, and new septa are formed in the exocœles on either side of them, and so forth.

FIG. 16.—Tangential section of a larva of *Astroides calicularis* which has fixed itself on a piece of cork. *ec*, ectoderm; *en*, endoderm; *mg*, mesogloea; *m*, *m*, mesenteries; *a*, septum; *b*, basal plate formed of ellipsoids of carbonate of lime secreted by the basal ectoderm; *ep*, epitheca. (After von Koch.)

It is evident from an inspection of Figs. 16 and 17 that every septum is covered by a fold of endoderm, mesogloea, and ectoderm, and is in fact pushed into the cavity of the zooid from without. The zooid then is, as it were, moulded upon the corallum. When fully extended, the upper part of the zooid projects for some distance out of the calicle, and its wall is reflected for some distance over the lip of the latter, forming a fold of soft tissue extending to a greater or less distance over the theca, and containing in most cases a cavity continuous over the lip of the calicle with the cœlenteron. This fold of tissue is known as the *edge-zone*. In some corals the septa are solid imperforate plates of calcite, and their peripheral ends are either firmly welded together, or are united by interstitial pieces so as to form an imperforate theca. In others the peripheral ends of the septa are united only by bars or trabeculæ, so that the theca is perforate, and in many such perforate corals the septa themselves are pierced by numerous perforations. In the former, which have been called aporose corals, the only communication between the cavity of the edge-zone and the general cavity of the zooid is by way of the lip of the calicle; in the latter, or perforate corals, the theca is permeated by numerous branching and anastomosing canals lined by endoderm, which place the cavity of the edge-zone in communication with the general cavity of the zooid.

A large number of corals, both aporose and perforate, are colonial. The colonies are produced either by budding or division. In the former case the young daughter zooid, with its corallum, arises wholly outside the cavity of the parent zooid, and the component parts of the young corallum, septa, theca, columella, &c., are formed anew in every individual produced. In division a vertical constriction divides a zooid into two equal or unequal parts, and the several parts of the two corals thus produced are severally derived from the corresponding parts of the dividing corallum. In colonial corals a bud is always formed from the edge-zone, and this bud develops into a new zooid with its corallum. The cavity of the bud in an aporose coral (Fig. 18, A, C) does not communicate directly with that of the parent form, but through the medium of the edge-zone.

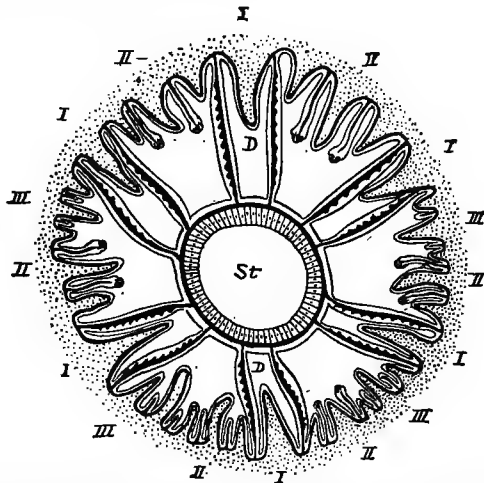

FIG. 17.—Transverse section through a zooid of *Cladocora*. The corallum shaded with dots, the mesogloea represented by a thick line. Thirty-two septa are present, six in the entocoelae of the primary cycle of mesenteries, I; six in the entocoelae of the secondary cycle of mesenteries, II; four in the entocoelae of the tertiary cycle of mesenteries, III, only four pairs of the latter being developed; and sixteen in the entocoelae between the mesenterial pairs. D, D', direct mesenteries; st, stomodæum. (After Duerden.)

As growth proceeds, and parent and bud become separated farther from one another, the edge-zone forms a sheet of soft tissue, bridging over the space between the two, and resting upon projecting spines of the corallum. This sheet of tissue is called the *cœnosarc*. Its lower surface is clothed with a layer of calicoblasts which continue to secrete carbonate of lime, giving rise to a secondary deposit which more or less fills up the spaces between the individual coralla, and is distinguished as *cœnenchyme*. This *cœnenchyme* may be scanty, or may be so abundant that the individual corallites produced by budding seem to be immersed in it. Budding takes place in an analogous manner in perforate corals (Fig. 18, B), but the presence of the canal system in the perforate theca leads to a modification of the process. Buds arise from the edge-zone which already communicate with the cavity of the zooid by the canals. As the buds develop the canal system becomes much extended, and calcareous tissue is deposited between the network of canals, the confluent edge-zones of mother zooid and bud forming a *cœnosarc*. As the process continues a number of calicles are formed, imbedded in a spongy tissue in which the canals ramify, and it is impossible to say where the theca of one corallite ends and that of another begins. In the formation of colonies by division a constriction at right angles to the long axis of the mouth involves first the mouth, then the peristome, and finally the calyx itself, so that the previously single corallite becomes divided into two (Fig. 18, E). After division the corallites continue to grow upwards, and their zooids may remain united by a bridge of soft tissue or *cœnosarc*. But in some cases as they grow

farther apart, this continuity is broken, each corallite has its own edge-zone, and internal continuity is also broken by the formation of dissepiments within each calicle, all organic connexion between the two zooids being eventually lost. Massive meandrine corals are produced by continual repetition of a process of incomplete division, involving the mouth and to some extent the peristome: the calyx, however, does not divide, but elongates to form a characteristic meandrine channel containing several zooid mouths.

Corals have been divided into *Aporosa* and *Perforata*, according as the theca and septa are compact and solid, or

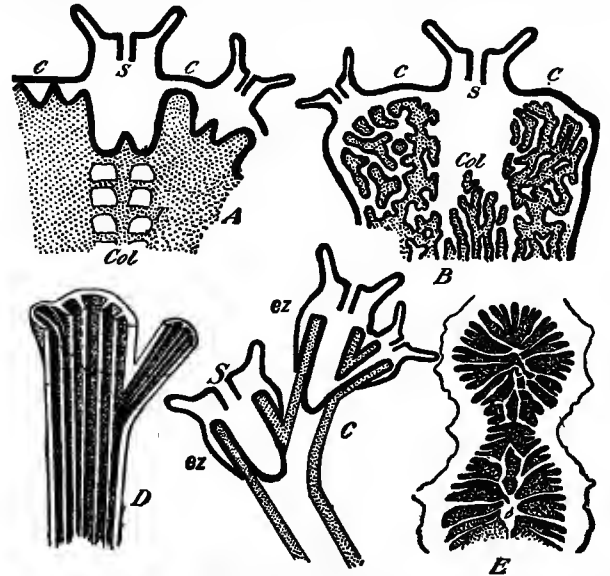

FIG. 18.—A, Schematic longitudinal section through a zooid and bud of *Stylophora digitata*. (C, original; the rest after von Koch.)

are perforated by pores containing canals lined by endoderm. The division is in many respects convenient for descriptive purposes, but recent researches show that it does not accurately represent the relationships of the different families. Various attempts have been made to classify corals according to the arrangement of the septa, the characters of the theca, the microscopic structure of the corallum, and the anatomy of the soft parts. The last-named method has proved little more than that there is a remarkable similarity between the zooids of all recent corals, the differences which have been brought to light being for the most part secondary and valueless for classificatory purposes. On the other hand, the study of the anatomy and development of the zooids has thrown much light upon the manner in which the corallum is formed, and it is now possible to infer the structure of the soft parts from a microscopical examination of the septa, theca, &c., with the result that unexpected relationships have been shown to exist between corals previously supposed to stand far apart. This has been particularly the case with the group of Palæozoic corals, formerly classed together as *Rugosa*. In many of these so-called rugose forms the septa have a characteristic arrangement, differing from that of recent corals chiefly in the fact that they show a tetrameral instead of a hexamerous symmetry. Thus in the family *Stauridæ* there are four chief septa whose inner ends unite in the middle of the calicle to form a false columella, and in the *Zaphrentidæ* there are many instances of an arrangement, such as that depicted in Fig. 19, which represents the

septal arrangement of *Streptelasma corniculum* from the lower Silurian. In this coral the calicle is divided into quadrants by four principal septa, the *main septum*, *counter septum*, and two *alar septa*. The remaining septa are so disposed that in the quadrants abutting on the chief septum they converge towards that septum, whilst in the other quadrants they converge towards the alar septa. The secondary septa show a regular gradation in size, and, assuming that the smallest were the most recently formed, it will be noticed that in the chief quadrants the youngest septa lie nearest to the main septum; in the other quadrants the youngest septa lie nearest to the alar septa. This arrangement, however, is by no means characteristic

Fig. 19.—Diagram of the arrangement of the septa in a Zaphrentid coral. *m*, main septum; *c*, counter septum; *a*, *a*, alar septa.

even of the Zaphrentidæ, and in the family *Cyathophyllidæ* most of the genera exhibit a radial symmetry in which no trace of the bilateral arrangement described above is recognizable, and indeed in the genus *Cyathophyllum* itself a radial arrangement is the rule. The connexion between the *Cyathophyllidæ* and modern *Astræidæ* is shown by *Moseleya latistellata*, a living reef-building coral from Torres Strait. The general structure of this coral leaves no doubt that it is closely allied to the *Astræidæ*, but in the young calicles a tetrameral symmetry is indicated by the presence of four large septa placed at right angles to one another. Again, in the family *Amphistraeidæ* there is commonly a single septum much larger than the rest, and it has been shown that in the young calicles, e.g., of *Thecidiosmilia*, two septa, corresponding to the main- and counter-septa of *Streptelasma*, are first formed, then two alar septa, and afterwards the remaining septa, the latter taking on a generally radial arrangement, though the original bilaterality is marked by the preponderance of the main septum. As the microscopic character of the corallum of these extinct forms agrees with that of recent corals, it may be assumed that the anatomy of the soft parts also was similar, and the tetrameral arrangement, when present, may obviously be referred to a stage when only the first two pairs of Edwardsian mesenteries were present and septa were formed in the intervals between them.

Space forbids a discussion of the proposals to classify corals after the minute structure of their coralla, but it will suffice to say that it has been shown that the septa of all corals are built up of a number of curved bars called trabeculæ, each of which is composed of a number of nodes. In many secondary corals (*Cyclolites*, *Thamnastrea*) the trabeculæ are so far separate that the individual bars are easily recognizable, and each looks something like a bamboo owing to the thickening of the two ends of each node. The trabeculæ are united together by these thickened internodes, and the result is a fenestrated septum, which in older septa may become solid and aporose by continual deposit of calcite in the fenestræ. Each node of a trabecula may be simple—i.e., have only one centre of calcification, or may be compound. The septa of modern perforate corals are shown to have a structure nearly identical with that of the secondary forms, but the trabe-

culæ and their nodes are only apparent on microscopical examination. The aporose corals, too, have a practically identical structure, their compactness being due to the union of the trabeculæ throughout their entire lengths instead of at intervals, as in the Perforata. Further, the trabeculæ may be evenly spaced throughout the septum, or may be grouped together, and this feature is probably of value in estimating the affinities of corals.

In the present state of our knowledge the Zoantharia, in which a primary cycle of six couples of mesenteries is (or may be inferred to be) completed by the addition of two pairs to the eight Edwardsian mesenteries, and succeeding cycles are formed in the exocœles of the pre-existing mesenterial cycles, may be classed in an order ACTINIIDEA, and this may be divided into the sub-orders *Malacactiniæ*, comprising the soft-bodied Actinians, such as *Actinia*, *Sagartia*, *Bunodes*, &c., and the *Scleractiniæ*, comprising the corals. The *Scleractiniæ* may best be divided into groups of families which appear to be most closely related to one another, but it should not be forgotten that there is great reason to believe that many if not most of the extinct corals must have differed from modern Actiniidea in mesenterial characters, and may have only possessed Edwardsian mesenteries, or even have possessed only four mesenteries, in this respect showing close affinities to the *Stauromedusæ*. Moreover, there are some modern corals in which the secondary cycle of mesenteries departs from the Actinian plan. For example, Duerden has shown that in *Porites* the ordinary zooids possess only six couples of mesenteries arranged on the Actinian plan. But some zooids grow to a larger size and develop a number of additional mesenteries, which arise either in the sulcar or the sulcular entocœle, much in the same manner as in *Cerianthus*. Bearing this in mind, the following arrangement may be taken to represent the most recent knowledge of coral structure:—

- | | |
|----------|--|
| Group A. | Family 1. ZAPHRENTIDÆ.—Solitary Palæozoic corals with an epithecal wall. Septa numerous, arranged pinnately with regard to four principal septa. Tabulæ present. One or more pits or fossulæ present in the calicle. Typical genera— <i>Zaphrentis</i> , Raf. <i>Amplexus</i> , M. Edw. and H. <i>Streptelasma</i> , Hall. <i>Omphyma</i> , Raf. |
| | Family 2. TURBINOLIDÆ.—Solitary, rarely colonial corals, with radially arranged septa and without tabulæ. Typical genera— <i>Flabellum</i> , Lesson. <i>Turbinolia</i> , M. Edw. and H. <i>Caryophyllia</i> , Lamarck. <i>Sphenotrochus</i> , Moseley, &c. |
| | Family 3. AMPHISTRÆIDÆ.—Mainly colonial, rarely solitary corals, with radial septa, but bilateral arrangement indicated by persistence of a main septum. Typical genera— <i>Amphistraea</i> , Étallon. <i>Thecidiosmilia</i> . |
| | Family 4. STYLINIDÆ.—Colonial corals allied to the Amphistraeidæ, but with radially symmetrical septa arranged in cycles. Typical genera— <i>Stylina</i> , Lamarck (Jurassic). <i>Convexastraea</i> , D'Orb. (Jurassic). <i>Isastraea</i> , M. Edw. and H. (Jurassic). Ogilvie refers the modern genus <i>Galaxea</i> to this family. |
| Group B. | Family 5. OCLINIDÆ.—Branching or massive aporose corals, the calices projecting above the level of a compact cœnecyme formed from the cœnosarc which covers the exterior of the corallum. Typical genera— <i>Lophohelia</i> , M. Edw. and H. <i>Oculina</i> , M. Edw. and H. |
| | Family 6. POCILLOPORIDÆ.—Colonial branching aporose corals, with small calices sunk in the cœnecyme. Tabulæ present, and two larger septa, an axial and abaxial, are always present, with traces of ten smaller septa. Typical genera— <i>Pocillopora</i> , Lamarck. <i>Seriatorpora</i> , Lamarck. |
| | Family 7. MADREPORIDÆ.—Colonial branching or palmate perforate corals, with abundant trahecular cœnecyme. Theca porous; septa compact and reduced in number. Typical genera— <i>Madrepora</i> , Linn. <i>Turbinaria</i> , Oken. <i>Montipora</i> , Quoy and G. |
| | Family 8. PORITIDÆ.—Incrusting or massive colonial perforate corals; calices usually in contact by their edges, sometimes disjunct and immersed in cœnecyme. Theca and septa perforate. Typical genera— <i>Porites</i> , M. Edw. and H. <i>Goniopora</i> , Quoy and G. <i>Rhodaræa</i> , M. Edw. and H. |

- Group C. { Family 9. CYATHOPHYLLIDÆ.—Solitary and colonial aporose corals, Tabulæ and vesicular endotheca present. Septa numerous, generally radial, seldom pinnate. Typical genera—*Cyathophyllum*, Goldfuss (Devonian and Carboniferous). *Moseleya*, Quelch (recent).
- Family 10. ASTRÆIDÆ.—Aporose, mainly colonial corals, massive, branching, or mæandroid. Septa radial; dissepiments present; an epitheca surrounds the base of massive or mæandroid forms, but only surrounds individual coralites in simple or branching forms. Typical genera—*Goniastrea*, M. Edw. and H. *Heliastrea*, M. Edw. and H. *Mæandrina*, Lam. *Cæloria*, M. Edw. and H. *Favia*, Oken.
- Family 11. FUNGIDÆ.—Solitary and colonial corals, with numerous radial septa united by synapticulæ. Typical genera—*Lophoseris*, M. Edw. and H. *Thamnastræa*, Le Sauvage. *Leptophyllia*, Reuss (Jurassic and Cretaceous). *Fungia*, Dana. *Siderastrea*, Blainv.
- Group D. { Family 12. EUPSAMMIDÆ.—Solitary or colonial perforate corals, branching, massive, or encrusting. Septa radial; the primary septa usually compact, the remainder perforate. Theca perforate. Synapticula present in some genera. Typical genera—*Stephanophyllia*, Michelin. *Eupsammia*, M. Edw. and H. *Astroïdes*, Blainv. *Rhodopsammia*, M. Edw. and H. *Dendrophyllia*, M. Edw. and H.
- Group E. { Family 13. CYSTIPHYLLIDÆ.—Solitary corals with rudimentary septa, and the calice filled with vesicular endotheca. Genera—*Cystiphyllum*, Lonsdale (Silurian and Devonian). *Goniophyllum*, M. Edw. and H. (In this Silurian genus the calyx is provided with a movable operculum, consisting of four paired triangular pieces, the bases of each being attached to the sides of the calyx, and their apices meeting in the middle when the operculum is closed.) *Calceola*, Lam. (In this Devonian genus there is a single semicircular operculum furnished with a stout median septum and numerous feebly developed secondary septa. The calyx is triangular in section, pointed below, and the operculum is attached to it by hinge-like teeth.)

Coral formations.

Many species of corals are widely distributed, and are found at all depths both in warmer and colder seas. *Lophohelia prolifera* and *Dendrophyllia ramea* form dense beds at a depth of from 100 to 200 fathoms off the coasts of Norway, Scotland, and Portugal, and the *Challenger* and other deep-sea dredging expeditions have brought up corals from great depths in the Pacific and Atlantic oceans. But the larger number of species, particularly the more massive kinds, occur only in tropical seas in shallow waters, whose mean temperature does not fall below 68° Fahr., and they do not flourish unless the temperature is considerably higher. These conditions of temperature are found in a belt of ocean which may roughly be indicated as lying between the 28th N. and S. parallels. Within these limits there are numerous reefs and islands formed of coral intermixed with the calcareous skeletons of other animals, and their formation has long been a matter of dispute among naturalists and geologists.

Coral formations may be classed as fringing or shore reefs, barrier reefs, and atolls. *Fringing reefs* are platforms of coral rock extending no great distance from the shores of a continent or island. The seaward edge of the platform is usually somewhat higher than the inner part, and is often awash at low water. It is intersected by numerous creeks and channels, especially opposite those places where streams of fresh water flow down from the land, and there is usually a channel deep enough to be navigable by small boats between the edge of the reef and the land. The outer wall of the reef is rather steep, but descends into a comparatively shallow sea. Since corals are killed by fresh water or by deposition of mud or sand, it is obvious that the outer edge of the reef is the region of most active coral growth, and the boat channel and the passages leading into it from the open sea have been formed by the suppression of coral growth by one of the

above-mentioned causes, assisted by the scour of the tides and the solvent action of sea-water. *Barrier reefs* may be regarded as fringing reefs on a large scale. The great Australian barrier reef extends for no less a distance than 1250 miles from Torres Strait in 9° 5' S. lat. to Lady Elliot island in 24° S. lat. The outer edge of a barrier reef is much farther from the shore than that of a fringing reef, and the channel between it and the land is much deeper. Opposite Cape York the seaward edge of the great Australian barrier reef is nearly 90 miles distant from the coast, and the maximum depth of the channel at this point is nearly 20 fathoms. As is the case in a fringing reef, the outer edge of a barrier reef is in many places awash at low tides, and masses of dead coral and sand may be piled up on it by the action of the waves, so that islets are formed which in time are covered with vegetation. These islets may coalesce and form a strip of dry land lying some hundred yards or less from the extreme outer edge of the reef, and separated by a wide channel from the mainland. Where the barrier reef is not far from the land there are always gaps in it opposite the mouths of rivers or considerable streams. The outer wall of a barrier reef is steep, and frequently, though not always, descends abruptly into great depths. In many cases in the Pacific Ocean a barrier reef surrounds one or more island peaks, and the strip of land on the edge of the reef may encircle the peaks with a nearly complete ring. An *atoll* is a ring-shaped reef, either awash at low tide or surmounted by several islets, or more rarely by a complete strip of dry land surrounding a central lagoon. The outer wall of an atoll generally descends with a very steep but irregular slope to a depth of 500 fathoms or more, but the lagoon is seldom more than 20 fathoms deep, and may be much less. Frequently, especially to the leeward side of an atoll, there may be one or more navigable passages leading from the lagoon to the open sea.

Though corals flourish everywhere under suitable conditions in tropical seas, coral reefs and atolls are by no means universal in the torrid zone. The Atlantic Ocean is remarkably free from coral formations, though there are numerous reefs in the West Indian islands, off the south coast of Florida, and on the coast of Brazil. The Bermudas also are coral formations, their high land being formed by sand accumulated by the wind and cemented into rock, and are remarkable for being the farthest removed from the equator of any recent reefs, being situated in 32° N. lat. In the Pacific Ocean there is a vast area thickly dotted with coral formations, extending from 5° N. lat. to 25° S. lat., and from 130° E. long. to 145° W. long. There are also extensive reefs in the westernmost islands of the Hawaiian group in about 25° N. lat. In the Indian Ocean, the Laccadive and Maldive islands are large groups of atolls off the west and south-west of India. Still farther south is the Chagos group of atolls, and there are numerous reefs off the north coast of Madagascar, at Mauritius, Bourbon, and the Seychelles. The Cocos-Keeling Islands, in 12° S. lat. and 96° E. long., are typical atolls in the eastern part of the Indian Ocean.

The remarkable characters of barrier reefs and atolls, their isolated position in the midst of the great oceans, the seemingly unfathomable depths from which they rise, their peaceful and shallow lagoons and inner channels, their narrow strips of land covered with cocoa-nut palms and other vegetation, and rising but a few feet above the level of the ocean, naturally attracted the attention of the earlier navigators, who formed sundry speculations as to their origin. The poet-naturalist Chamisso was the first to propound a definite theory of the origin of atolls and encircling reefs, attributing their peculiar features to the

natural growth of corals and the action of the waves. He pointed out that the larger and more massive species of corals flourish best on the outer sides of a reef, whilst the more interior corals are killed or stunted in growth by the accumulation of coral and other debris. Thus the outer edge of a submerged reef is the first to reach the surface, and a ring of land being formed by materials piled up by the waves, an atoll with a central lagoon is produced. Chamisso's theory necessarily assumed the existence of a great number of submerged banks reaching nearly, but not quite, to the surface of the sea in the Pacific and Indian oceans, and the difficulty of accounting for the existence of so many of these led Darwin to reject his views and bring forward an explanation which may be called the theory of *subsidence*. Starting from the well-known premise that reef-building species of corals do not flourish in a greater depth of water than 20 fathoms, Darwin argued that all coral islands must have a rocky base, and that it was inconceivable that, in such large tracts of sea as occur in the Pacific and Indian oceans, there should be a vast number of submarine peaks or banks all rising to within 20 or 30 fathoms of the surface

coral reefs between 1838 and 1842, but it was not long before it was attacked by other observers. In 1851 Louis Agassiz produced evidence to show that the reefs off the south coast of Florida were not formed during subsidence, and in 1863 Karl Semper showed that in the Pelew islands there is abundant evidence of recent upheaval in a region where both atolls and barrier-reefs exist. Latterly, many instances of recently upraised coral formations have been described by Wharton, Guppy, Gardiner, and others, and Alexander Agassiz and Murray have brought forward a mass of evidence tending to shake the subsidence theory to its foundations. Murray has pointed out that the deep-sea soundings of the *Tuscarora* and *Challenger* have proved the existence of a large number of submarine elevations rising out of a depth of 2000 fathoms or more to within a few hundred fathoms of the surface. The existence of such banks was unknown to Darwin, and removes his objections to Chamisso's theory. For although they may at first be too far below the surface for reef-building corals, they afford a habitat for numerous echinoderms, molluscs, crustacea, and deep-sea corals, whose skeletons accumulate on their summits, and they further receive a constant rain of the calcareous and silicious skeletons of minute organisms which teem in the waters above. By these agencies the banks are gradually raised to the lowest depth at which reef-building corals can flourish, and once these establish themselves they will grow more rapidly on the periphery of the bank, because they are more favourably situated as regards food-supply. Thus the reef will rise to the surface as an atoll, and the nearer it approaches the surface the more will the corals on the exterior faces be favoured, and the more will those in the centre of the reef decrease, for experiment has shown that the minute pelagic organisms on which corals feed are far less abundant in a lagoon than in the sea outside. Eventually, as the margin of the reef rises to the surface and material is accumulated upon it to form islets or continuous land, the coral growth in the lagoon will be feeble, and the solvent action of seawater and the scour of the tide will tend to deepen the lagoon. Thus the considerable depth of some lagoons, amounting to 40 or 50 fathoms, may be accounted for. The observations of Guppy in the Solomon Islands have gone far to confirm Murray's conclusions, since he found in the islands of Ugi, Santa Anna, and Treasury and Stirling islands unmistakable evidences of a nucleus of volcanic rock, covered with soft earthy-bedded deposits several hundred feet thick. These deposits are highly fossiliferous in parts, and contain the remains of pteropods, lamellibranchs, and echinoderms, imbedded in a foraminiferous deposit mixed with volcanic debris, like the deep-sea muds brought up by the *Challenger*. The flanks of these elevated beds are covered with coralline limestone rocks varying from 100 to 16 feet in thickness. One of the islands, Santa Anna, has the form of an upraised atoll, with a mass of coral limestone 80 feet in vertical thickness, resting on a friable and sparingly argillaceous rock resembling a deep-sea deposit. A. Agassiz, in a number of important researches on the Florida reefs, the Bahamas, the Bermudas, the Fiji Islands, and the Great Barrier-reef of Australia, has further shown that many of the peculiar features of these coral formations cannot be explained on the theory of subsidence, but are rather attributable to the natural growth of corals on banks formed by prevailing currents, or on extensive shore platforms or submarine flats formed by the erosion of pre-existing land surfaces.

FIG. 20.—Diagram showing the formation of an atoll during subsidence. (After Darwin.) The lower part of the figure represents a barrier reef surrounding a central peak. A, A, Outer edge of the barrier reef at the sea-level; the coconut trees indicate dry land formed on the edges of the reef; L, L, lagoon channel; A', A', outer edges of the atoll formed by upgrowth of the coral during the subsidence of the peak; L', lagoon of the atoll. The vertical scale is considerably exaggerated as compared with the horizontal scale.

and none emerging above it. But on the supposition that the atolls and encircling reefs were formed round land which was undergoing a slow movement of subsidence their structure could easily be explained. Take the case of an island consisting of a single high peak. At first the coral growth would form a fringing reef clinging to its shores. As the island slowly subsided into the ocean the upward growth of coral would keep the outer rim of the reef level with or within a few fathoms of the surface, so that, as subsidence proceeded, the distance between the outer rim of the reef and the sinking land would continually increase, with the result that a barrier-reef would be formed separated by a wide channel from the central peak. As corals and other organisms with calcareous skeletons live in the channel, their remains, as well as the accumulation of coral and other debris thrown over the outer edge of the reef, would maintain the channel at a shallower depth than that of the ocean outside. Finally, if the subsidence continued, the central peak would disappear beneath the surface, and an atoll would be left consisting of a raised margin of reef surrounding a central lagoon, and any pause during the movement of subsidence would result in the formation of raised islets or a strip of dry land along the margin of the reef. Darwin's theory was published in 1842, and found almost universal acceptance, both because of its simplicity and its applicability to every known type of coral-reef formation, including such difficult cases as the Great Chagos Bank, a huge submerged atoll in the Indian Ocean.

Darwin's theory was adopted and strengthened by Dana, who had made extensive observations among the Pacific

In face of this accumulated evidence, it must be admitted that the subsidence theory of Darwin is inapplicable to a large number of coral reefs and islands, but it is hardly

possible to assert, as Murray does, that no atolls or barrier-reefs have ever been developed after the manner indicated by Darwin. The most recent research on the structure of coral reefs has also been the most thorough and the most convincing. It is obvious that, if Murray's theory were correct, a bore hole sunk deep into an atoll would pass through some 100 feet of coral rock, then through a greater or less thickness of argillaceous rock, and finally would penetrate the volcanic rock on which the other materials were deposited. If Darwin's theory is correct, the boring would pass through a great thickness of coral rock, and finally, if it went deep enough, would pass into the original rock which subsided below the waters. An expedition sent out by the Royal Society of London started in 1896 for the island of Funafuti, a typical atoll of the Ellice group in the Pacific Ocean, with the purpose of making a deep boring to test this question. The first attempt was not successful, for at a depth of 105 feet the refractory nature of the rock stopped further progress. But a second attempt, under the management of Prof. Edgeworth David of Sydney, proved a complete success. With improved apparatus, the boring was carried down to a depth of 697 feet (116 fathoms), and a third attempt carried it down to 1114 feet (185 fathoms). The boring proves the existence of a mass of pure limestone of organic origin to the depth of 1114 feet, and there is no trace of any other rock. The organic remains found in the core brought up by the drill consist of corals, foraminifera, calcareous algæ, and other organisms. The results of the examination of the core had not been published at the time this article was written, but, by the courtesy of Professor Judd, the writer has been able to examine the core and satisfy himself as to the truth of the above statements. A boring was also made from the deck of a ship into the floor of the lagoon, which shows that under 100 feet of water there exists at the bottom of the lagoon a deposit more than 100 feet thick, consisting of the remains of a calcareous alga, *Halimeda opuntia*, mixed with abundant foraminifera. At greater depths, down to 245 feet, the same materials, mixed with the remains of branching madreporæ, were met with, and further progress was stopped by the existence of solid masses of coral, fragments of porites, madrepora, and heliopora having been brought up in the core. These are shallow-water corals, and their existence at a depth of nearly 46 fathoms buried beneath a mass of halimeda and foraminifera, is clear evidence of recent subsidence. Halimeda grows abundantly over the floor of the lagoon of Funafuti, and has been observed in many other lagoons. The writer collected a quantity of it in the lagoon of Diego Garcia in the Chagos group. The boring demonstrates that the lagoon of Funafuti has been filled up to an extent of at least 245 feet (nearly 41 fathoms), and this fact accords well with Darwin's theory, but is incompatible with that of Murray. In the present state of our knowledge it seems reasonable to conclude that coral reefs are formed wherever the conditions suitable for growth exist, whether in areas

of subsidence, elevation, or rest. A considerable number of reefs, at all events, have not been formed in areas of subsidence, and of these the Florida reefs, the Bermudas, the Solomon islands, and possibly the great barrier-reef of Australia are examples. Funafuti would appear to have been formed in an area of subsidence, and it is quite probable that the large groups of low-lying islands in the Pacific and Indian oceans have been formed under the same conditions. At the same time, it must be remembered that the atoll or barrier-reef shape is not necessarily evidence of formation during subsidence, for the observations of Semper, A. Agassiz, and Guppy are sufficient to prove that these forms of reefs may be produced by the natural growth of coral, modified by the action of waves and currents in regions in which subsidence has certainly not taken place.

AUTHORITIES.—The following list contains only the names of the more important and more general works on the structure and classification of corals and on coral reefs. For a fuller bibliography the works marked with an asterisk should be consulted:—1. *A. ANDRES. *Fauna und Flora des Golfes von Neapel*, ix. 1884.—2. H. M. BERNARD. Anthropology.—The following additional observations, supplementing the article ANTHROPOLOGY in *Ency. Brit.*, 9th ed., vol. ii., are placed under headings corresponding to those previously adopted.

Man's Place in Nature.—In the original article use is made of the exposition of the theory of human development, as viewed on its physical side, by Professor

Huxley (see his *Man's Place in Nature*, 1863; reprinted in *Collected Essays*, vol. vii.). Huxley's argument has, on the whole, stood its ground, and a reproduction of his series of skeletons is given in our Plate (Fig. 2) as serving better than a detailed anatomical statement. Its significance in the problem of human descent requires some explanation. The acknowledgment of man's structural similarity with the anthropomorphic species nearest approaching him was made by Linnæus, who, in his

Systema Naturæ (1735) grouped them together as the highest order of Mammalia, to which he gave the name of Primates. The *Amœnitates Academicæ* (vol. vi., Leyden, 1764), published under the auspices of Linnæus, contains a remarkable picture which illustrates a discourse by his disciple Hoppius, and is here reproduced in the Plate, Fig. 1. In this picture, which shows the crudeness of the zoological notions current in the 18th century both as to men and apes, there are set in a row four figures: (a) a recognizable orang-utan, sitting and holding a staff; (b) a chimpanzee, absurdly humanized as to head, hands, and feet; (c) a hairy woman, with a tail a foot long; (d) another woman, more completely coated with hair. The great Swedish naturalist was possibly justified in treating the two latter creatures as quasi-human, for they seem to be grotesque exaggerations of such tailed and hairy human beings as really, though rarely, occur, and are apt to be exhibited as monstrosities (see Bastian and Hartmann, *Zeitschrift für Ethnologie*, Index, "Geschwânzte Menschen"; Gould and Pile, *Anomalies and Curiosities of Medicine*, 1897). To Linnæus, however, they represented normal anthropomorpha or man-like creatures, vouched for by visitors to remote parts of the world. This opinion of the Swedish naturalist seems to have been little noticed in Great Britain till it was taken up by the learned but credulous Scots judge, Lord Monboddo (see his *Origin and Progress of Language*, 1774, &c.; *Antient Metaphysics*, 1778). He had not heard of the tailed men till he met with them in the work of Linnæus, with whom he entered into correspondence, with the result that he enlarged his range of mankind with races of sub-human type. One was founded on the description by the Swedish sailor Niklas Köping of the ferocious men with long tails inhabiting the Nicobar Islands. Another comprised the orang-utans of Sumatra, who were said to take men captive and set them to work as slaves. One of these apes, it was related, served as a sailor on board a Jamaica ship, and used to wait on the captain. These are stories which seem to carry their own explanation. When the Nicobar Islands were taken over by the British Government two centuries later, the native warriors were still wearing their peculiar loin-cloth hanging behind in a most tail-like manner (E. H. Man, *Journal Anthropological Institute*, vol. xv. p. 442). As for the story of the orang-utan cabin boy, this may even be verbally true, it being borne in mind that in the Malay languages the term *orang-utan*, "man of the forest," was originally used for inland forest natives and other rude men, rather than for the *myias* apes to which it has come to be generally applied by Europeans. The speculations as to primitive man connected with these stories diverted the British public, headed by Dr Johnson, who said that Monboddo was "as jealous of his tail as a squirrel." Linnæus's primarily zoological classification of man did not, however, suit the philosophical opinion of the time, which responded more readily to the systems represented by Buffon, and later by Cuvier, in which the human mind and soul formed an impassable wall of partition between him and other mammalia, so that the definition of man's position in the animal world was treated as not belonging to zoology, but to metaphysics and theology. It has to be borne in mind that Linnæus, plainly as he recognized the likeness of the higher simian and the human types, does not seem to have entertained the thought of accounting for this similarity by common descent. It satisfied his mind to consider it as belonging to the system of nature, as indeed remained the case with a greater anatomist of the following century, Richard Owen. The present drawing, which under the authority of Linnæus shows an anthropomorphic series from which the normal type of man, the *homo sapiens*, is

conspicuously absent, brings zoological similarity into view without suggesting kinship to account for it. There are few ideas more ingrained in ancient and low civilization than that of relationship by descent between the lower animals and man. Savage and barbaric religions recognize it, and the mythology of the world has hardly a more universal theme. But in educated Europe such ideas had long been superseded by the influence of theology and philosophy, with which they seemed too incompatible. In the 19th century, however, Lamarck's theory of the development of new species by habit and circumstance led through Wallace and Darwin to the doctrines of the hereditary transmission of acquired characters, the survival of the fittest, and natural selection. Thenceforward it was impossible to exclude a theory of descent of man from ancestral beings whom zoological similarity connects also, though by lines of descent not at all clearly defined, with ancestors of the anthropomorphic apes. In one form or another such a theory of human descent has in our time become part of an accepted framework of zoology, if not as a demonstrable truth, at any rate as a working hypothesis which has no effective rival.

The new development from Linnæus's zoological scheme which has thus ensued appears in Huxley's diagram of simian and human skeletons (Fig. 2, (a) gibbon; (b) orang; (c) chimpanzee; (d) gorilla; (e) man). Evidently suggested by the Linnean picture, this is brought up to the modern level of zoology, and continued on to man, forming an introduction to his zoological history hardly to be surpassed. Some of the main points it illustrates may be briefly stated here, the reader being referred for further information to Huxley's *Essays*. In tracing the osteological characters of apes and man through this series, the general system of the skeletons, and the close correspondence in number and arrangement of vertebræ and ribs, as well as in the teeth, go far towards justifying the opinion of hereditary connexion. At the same time, the comparison brings into view differences in human structure adapted to man's pre-eminent mode of life, though hardly to be accounted its chief causes. It may be seen how the arrangement of limbs suited for going on all-fours belongs rather to the apes than to man, and walking on the soles of the feet rather to man than the apes. The two modes of progression overlap in human life, but the child's tendency when learning is to rest on the soles of the feet and the palms of the hands, unlike the apes, which support themselves on the sides of the feet and the bent knuckles of the hands. With regard to climbing, the long stretch of arm and the grasp with both hands and feet contribute to the arboreal life of the apes, contrasting with what seem the mere remains of the climbing habit to be found even among forest savages. On the whole, man's locomotive limbs are not so much specialized to particular purposes, as generalized into adaptation to many ends. As to the mechanical conditions of the human body, the upright posture has always been recognized as the chief. To it contributes the balance of the skull on the cervical vertebræ, while the human form of the pelvis provides the necessary support to the intestines in the standing attitude. The marked curvature of the vertebral column, by breaking the shock to the neck and head in running and leaping, likewise favours the erect position. The lowest coccygeal vertebræ of man remain as a rudimentary tail. While it is evident that high importance must be attached to the adaptation of the human body to the life of diversified intelligence and occupation he has to lead, this must not be treated as though it were the principal element of the superiority of man, whose comparison with all lower genera of mammals must be mainly directed to the intel-

lectual organ, the brain. Comparison of the brains of vertebrate animals brings into view the immense difference between the small, smooth brain of a fish or bird and the large and convoluted organ in man. In man, both size and complexity contribute to the increased area of the cortex or outer layer of the brain, which within the last few years has been fully ascertained to be the seat of the mysterious processes by which sensation furnishes the groundwork of thought. Schäfer (*Textbook of Physiology*, vol. ii. p. 697) thus defines it: "The cerebral cortex is the seat of the intellectual functions, of intelligent sensation or consciousness, of ideation, of volition, and of memory." Not to enter into the difficult details of comparison of the extent of this thinking layer in the higher apes and man, it may suffice to compare the absolute quantity of brain in the gorilla and average man, which has been estimated as 1 to 2. So evident is the preponderance, that it is plainly seen in the present series of skeletons which have already served so many purposes, and where the outside of the brainpan in each gives a rough measure of the brain contained within.

The wide acceptance of the Darwinian theory, as applied to the descent of man, has naturally roused anticipation that geological research, which provides evidence of the animal life of incalculably greater antiquity, would furnish fossil remains of some comparatively recent being intermediate between the anthropomorphic and the anthropic types. This expectation has hardly been fulfilled, but of late years the notion of a variety of the human race, geologically ancient, differing from any known in historic times, and with characters approaching the simian, has been supported by further discoveries. To bring this to the reader's notice, top and side views of three skulls, as placed together in the human development series in the Oxford University Museum, are represented in the Plate, for the purpose of showing the great size of the orbital ridges, which the reader may contrast with his own by a touch with his fingers on his forehead. The first (Fig. 3) is the famous Neanderthal skull from near Düsseldorf, described by Schaafhausen in Müller's *Archiv*, 1858; Huxley in Lyell, *Antiquity of Man*, p. 86, and in *Man's Place in Nature*. The second (Fig. 4) is the skull from the cavern of Spy in Belgium (De Puydt and Lohest, *Compte Rendu du Congrès de Namur*, 1886). The foreheads of these two skulls have an ape-like form, obvious on comparison with the simian skulls of the gorilla and other apes, and visible even in the small-scale figures in the Plate, Fig. 2. Among modern tribes of mankind the forehead of the Australian aborigines makes the nearest approach to this type, as was pointed out by Huxley. This brief description will serve to show the importance of a later discovery. At Trinil, in Java, in an equatorial region where, if anywhere, a being intermediate between the higher apes and man would seem likely to be found, Dr Dubois in 1891-92 excavated from a bed, considered by him to be of Sivalik formation (Pliocene), a thighbone which competent anatomists decide to be human, and a remarkably depressed calvaria or skull-cap (Fig. 5), bearing a certain resemblance in its proportions to the corresponding part of the simian skull. These remains were referred by their discoverer to an animal intermediate between man and ape, to which he gave the name of *Pithecanthropus erectus*, but the interesting discussions on the subject showed divergence of opinion among leading anatomists. At any rate, classing the Trinil skull as human, it may be described as tending towards the simian type more than any other known (Eug. Dubois, *Pithecanthropus erectus*, Batavia, 1894; *Trans. of Royal Dublin Soc.* vol. vi. 1898; *Journal Anthropological Institute*, vol. xxv. p. 240; *Nature*, vol. li. 1895).

Development of Civilization.—In recent years no such fundamental alteration has taken place in scientific views as to man's age on the earth, as had been brought about previously by the extension of his antiquity back from history into geology. It was an immense change in current opinion to substitute for a chronology of centuries a vague computation of hundreds of thousands of years. The new views, however, met with comparatively little opposition, partly because the way had been already broken by geology assigning to the strata of the earth an incalculable antiquity, and still more because the extension of the human period was no merely speculative doctrine, but rested on visible fact. It was an object-lesson on the largest scale to look across a valley like that of the Thames, and to imagine the vast time required for its excavation by the waters since the river drift-gravels were left high on the slopes, containing rude stone implements lying with the bones of the mammoth and rhinoceros, which plainly showed man to have been their contemporary. These stone implements in the Quaternary drift-gravels, and other relics of human art in the cave deposits, while furnishing the main proof of man's high antiquity, contain also evidence of his then state of culture. His drawings on bone or tusk found in the caves show no mean artistic power, as appears by the three specimens copied in the Plate. That representing two deer (Fig. 6) was found so early as 1852 in the breccia of a limestone cave on the Charente, and its importance recognized in a remarkable letter by Prosper Mérimée, as at once historically ancient and geologically modern (*Congrès d'Anthropologie et d'Archéologie Préhistoriques*, Copenhagen, 1869, p. 128). The other two are the famous mammoth from the cave of La Madelaine, on which the woolly mane and huge tusks of *Elephas primigenius* are boldly drawn (Fig. 7); and the group of man and horses (Fig. 8). There has been found one other contemporary portrait of man, where a hunter is shown stalking an aurochs.

That the men of the Quaternary period knew the savage art of producing fire by friction, and roasted the flesh on which they mainly subsisted, is proved by the fragments of charcoal found in the cave deposits, where also occur bone awls and needles, which indicate the wearing of skin clothing, like that of the modern Australians and Fuegians. Their bone lance-heads and dart-points were comparable to those of northern and southern savages. Particular attention has to be given to the stone implements used by these earliest known of mankind. The division of tribes in the stone implement stage into two classes, according to their proficiency in this most important art, furnishes in some respects the best means of determining their rank in general culture. In order to put this argument clearly before the reader, a few selected implements are figured in the Plate. The group in Fig. 9 contains tools and weapons of the Neolithic or New Stone Age, such as are dug up on European soil; they are evident relics of ancient populations who used them till replaced by metal. The stone hatchets are symmetrically shaped and edged by grinding, while the cutting flakes, scrapers, spear and arrow heads, are of high finish. Direct knowledge of the tribes who made them is scanty, but implements so similar in make and design having been in use in North and South America until modern times, it may be assumed for purposes of classification that the Neolithic peoples of the New World were at a similar barbarous level in industrial arts, social organization, moral and religious ideas. Such comparison, though needing caution and reserve, at once proved of great value to anthropology. When, however, there came to light from the drift-gravels and limestone caves of Europe the Palæolithic implements, of which some types are shown in the group (Fig.

Fig. 1.

Fig. 3.

Fig. 4.

Fig. 5.

10), the difficult problem presented itself what degree of general culture these rude implements belonged to. On mere inspection, their rudeness, their unsuitability for being hafted, and the absence of shaping and edging by the grindstone, mark their inferiority to the Neolithic implements. Their immensely greater antiquity was proved by their geological position and their association with a long-extinct fauna, and they were not, like the Neoliths, recognizable as corresponding closely to the implements used by modern tribes. There was at first a tendency to consider the Palæoliths as the work of men ruder than savages, if, indeed, their makers were to be accounted human at all. Since then, however, the problem has passed into a more manageable state. Stone implements, more or less approaching the European Palæolithic type, were found in Africa from Egypt southwards, where in such parts as Somaliland and Cape Colony they lie about on the ground, as though they had been the rough tools and weapons of the rude inhabitants of the land at no very distant period. The group in Fig. 11 in the Plate shows the usual Somaliland types. These facts tended to remove the mystery from Palæolithic man, though too little is known of the ruder ancient tribes of Africa to furnish a definition of the state of culture which might have co-existed with the use of Palæolithic implements. Information to this purpose, however, can now be furnished from a more outlying region. This is Tasmania, where, as in the adjacent continent of Australia, the survival of marsupial animals indicates long isolation from the rest of the world. Here, till far on into the 19th century, the Englishmen could watch the natives striking off flakes of stone, trimming them to convenient shape for grasping them in the hand, and edging them by taking off successive chips on one face only. The group in Fig. 12 shows ordinary Tasmanian forms, two of them being finer tools for scraping and grooving. (For further details reference may be made to H. Ling Roth, *The Tasmanians*, 2nd ed. 1899; R. Brough Smyth, *Aborigines of Victoria*, 1878, vol. ii.; *Papers and Proceedings of Royal Society of Tasmania*; and papers by the present writer in *Journal of the Anthropological Institute*.) The Tasmanians, when they came in contact with the European explorers and settlers, were not the broken outcasts they afterwards became. They were a savage people, perhaps the lowest in culture of any known, but leading a normal, self-supporting, and not unhappy life, which had probably changed little during untold ages. The accounts, imperfect as they are, which have been preserved of their arts, beliefs, and habits, thus present a picture of the arts, beliefs, and habits of tribes whose place in the Stone Age was a grade lower than that of Palæolithic man of the Quaternary period.

The Tasmanian stone implements, figured in the Plate, show their own use when it is noticed that the rude chipping forms a good hand-grip above, and an effective edge for chopping, sawing, and cutting below. But the absence of the long-shaped implements, so characteristic of the Neolithic and Palæolithic series, and serviceable as picks, hatchets, and chisels, shows remarkable limitation in the mind of these savages, who made a broad, hand-grasped knife their tool of all work to cut, saw, and chop with. Their weapons were the wooden club or waddy notched to the grasp, and spears of sticks, often crooked but well balanced, with points sharpened by tool or fire, and sometimes jagged. No spear-thrower or bow and arrow was known. The Tasmanian savages were crafty warriors and kangaroo-hunters, and the women climbed the highest trees by notching, in quest of opossums. Shell-fish and crabs were taken, and seals knocked on the head with clubs, but neither fish-hook nor fishing-net was known, and

indeed swimming fish were avoided as food. Meat and vegetable food, such as fern-root, was broiled over the fire, but boiling in a vessel was unknown. The fire was produced by the ordinary savage fire-drill. Ignorant of agriculture, with no dwellings but rough huts or break-winds of sticks and bark, without dogs or other domestic animals, these savages, until the coming of civilized man, roamed after food within their tribal bounds. Logs and clumsy floats of bark and grass enabled them to cross water under favourable circumstances. They had clothing of skins rudely stitched together with bark thread, and they were decorated with simple necklaces of kangaroo teeth, shells, and berries. Among their simple arts, plaiting and basket-work was one in which they approached the civilized level. The pictorial art of the Tasmanians was poor and childish, quite below that of the Palæolithic men of Europe. The Tasmanians spoke a fairly copious agglutinating language, well marked as to parts of speech, syntax, and inflexion. Numeration was at a low level, based on counting fingers on one hand only, so that the word for man (*puggana*) stood also for the number 5. The religion of the Tasmanians, when cleared from ideas apparently learnt from the whites, was a simple form of animism based on the shadow (*warrawa*) being the soul or spirit. The strongest belief of the natives was in the power of the ghosts of the dead, so that they carried the bones of relatives to secure themselves from harm, and they fancied the forest swarming with malignant demons. They placed weapons near the grave for the dead friend's soul to use, and drove out disease from the sick with the intruding ghost which had caused it. Of greater special spirits of Nature we find something vaguely mentioned. The earliest recorders of the native social life set down such features as their previous experience of rude civilized life had made them judges of. They notice the self-denying affection of the mothers, and the hard treatment of the wives by the husbands, polygamy, and the shifting marriage unions. But when we meet with a casual remark as to the tendency of the Tasmanians to take wives from other tribes than their own, it seems likely that they had some custom of exogamy which the foreigners did not understand. Meagre as is the information preserved of the arts, thoughts, and customs of these survivors from the lower Stone Age, it is of value as furnishing even a temporary and tentative means of working out the development of culture on a basis not of conjecture but of fact. (E. B. T.)

Anthropometry is a system of identifying and classifying individuals by measurement, invented for police purposes about 1880 by M. Bertillon of the *Service de la Sûreté* or criminal department of the prefecture of police in Paris, and since adopted in some form by nearly every civilized government. The system rests upon two assumptions, which may be taken to have been proved. The first is that the dimensions of certain bones and bony structures remain practically constant in the individual throughout adult life; and the second is that such dimensions vary so much in different persons that if several bones be measured very few individuals will be found to have all the measurements absolutely the same. Taken together, these facts provide the basis for an exact method of identifying at any future time a person who has once been measured, and of distinguishing between that person and others. Such a method might obviously be useful in any situation in which it is desirable to establish identity or prevent personation, but its most important application is in dealing with crime, and especially with "recidivists" or old offenders who have been previously convicted, and who endeavour to escape recognition by giving false accounts of themselves, and by

every other means in their power. In the case of small communities and local crime personal identification is usually a simple matter and presents little difficulty to the police, who are more or less familiar with all the persons with whom they are called upon to deal; but it becomes difficult or impossible with persons who travel from place to place, as the more important professional criminals do, and in great cities by sheer excess of numbers. Previously to the introduction of the Bertillon system the means relied upon were (1) the memory of warders and policemen, who often had to travel to distant places to view prisoners, (2) photographs, (3) written descriptions, with special reference to marks or other peculiarities. These things have their uses still, but by themselves they formed a very imperfect means of identification. The chief defects in practice were (1) frequent failure to identify, (2) liability to mis-identification—not very common but of the greatest importance to the innocent, (3) time, labour, and expense involved in searching records and circulating descriptions.

Anthropometry was designed to overcome all these defects. The great advantage claimed for it lies in the systematic recording on a uniform plan of the distinctive features of each criminal, and the classification of these records on the numerical basis afforded by measurement. The principle of classification may be explained as follows:—Five dimensions are taken as a basis, namely (1) length of head, (2) breadth of head, (3) length of left middle finger, (4) length of left foot, (5) length of left forearm. These were chosen by M. Bertillon chiefly on the ground that they are the most constant in the individual and the easiest to take accurately; but they may be varied without affecting the principle. Each of these is then divided into three classes:—(1) long, (2) medium, (3) short. Thus heads upwards of 191 millimetres in length are classed "long," those of 185 to 190 millimetres are "medium," and those of less than 185 are "short." Similarly with the breadth of head, length of middle finger, and so on. This division of the five dimensions into three classes each gives 3^5 or 243 classes, which are assumed to be approximately equal. Supposing, now, it is required to keep a register of 90,000 criminals, as contemplated by M. Bertillon, each represented by a card containing personal details, photograph, and other particulars. The first division by length of head will divide the 90,000 cards into three sections of 30,000 each; these are subdivided by breadth of head into nine subsections of 10,000 each, and again by the remaining measurements successively into 27 sets of 3300 each, 81 of 1100 each, and 243 of 370 each. The cards are kept in a cabinet, which is divided into sections and subsections corresponding to the measurements described, and eventually into drawers, representing the last subdivision. There are, therefore, 243 drawers, each containing about 370 cards. Then a further subdivision of the cards in each drawer is given by the height, the length of the little finger, and lastly by the colour of the eye. The height gives three subdivisions of 124 each, which are further divided into groups of 41 by the little finger, and finally into packets of 6 by the colour of the eye, of which seven varieties are distinguished. The practical working of the system can be readily understood. A prisoner is brought into the Prefecture; the police require to know his record, and whether previously convicted or not. He gives a name which is not found in the alphabetical register, kept in addition to the anthropometric register. Let us suppose that the name is false, and that he is really an old offender. In order to find out it is necessary to search the records. It is here that the anthropometric classification comes in. Instead of searching through photographic albums

and voluminous records, at the cost of much time and labour, and with a doubtful result, the authorities can, theoretically at least, lay their hands with certainty on the document required within a few minutes even among 90,000 others. The man is measured, and his head-length is found to be over 191 millimetres. He therefore falls under the "longs," and two-thirds of the registration cabinet, or 60,000 records, are at once eliminated. The head-breadth in like manner eliminates 20,000 more; and so on until the search comes down to a bundle of six or so, among which the suspect's card is found, with photograph, description, &c. The whole thing is entirely independent of names. The actual identification is made by means of the photograph and distinctive marks, if any. Some additional measurements, including the dimensions of the ear, are taken by M. Bertillon, but they are not essential. The system is still undergoing modification and improvement by the introduction of new features. An important addition is the finger-print process, described below.

The weak point in the system is the margin which has to be allowed for error in the measurements. M. Bertillon himself allows 1 millimetre, but with less skilful or less careful officers than those at the Paris Prefecture it may be necessary to allow more. This introduces a doubt into the classification, rendering it uncertain to which of two sections measurements near the dividing line really belong, and so increasing the area of search to a corresponding degree. In practice, however, the system has proved highly successful in France. A striking result is the great diminution in the number of habitual criminals who attempt to evade recognition; the inference is that they have learnt to regard the endeavour as futile.

In 1893 a departmental committee was appointed by the British Home Office to inquire into the anthropometric system and also into finger-prints. It reported in the following year, recommending the adoption of anthropometric classification by means of the five primary measurements described above; but for the further classification and actual identification it recommended the finger-print system elaborated by Mr Francis Galton in preference to the Bertillon secondary measurements, as being more scientific and more accurate. These recommendations were provisionally adopted with some modifications, and have been in use in England ever since. The actual measurements now taken are the following:—(1) head length, (2) head breadth, (3) face breadth, (4) left middle finger, (5) left cubit, (6) left foot, (7) height. These are entered on a form together with other details, including age, name, complexion, hair, eyes, and distinctive marks. The prisoner's photograph is also affixed in a space left vacant for the purpose. The reverse side of the same piece of paper is devoted to the finger-prints. Impressions of the thumb and four fingers of each hand are taken, both with the fingers together and each in a separate space. The papers are classified and arranged in sections to form a register in the manner already explained. It is to be noted, however, that owing to difference of judicial procedure the system is carried out in a somewhat different way in Great Britain, and is used to a much less extent than in France. The French law permits the arrest, detention, and interrogation of persons on mere suspicion, and the identification of "recidivists" at this stage is of great importance, because it places a powerful weapon in the hands of the police and of the examining magistrate in working up the case. It is also important for the protection of the innocent. All persons arrested are therefore measured at once by the police as a matter of routine, and this is done by specially trained and skilled officers at the identification bureau. The

English law only permits it to be done to persons committed for trial or under remand at the formal request of a chief constable. The measurements, therefore, are not taken by the police, but by prison officials, and the system is only applied to a comparatively small number of criminals. It is carried out, however, under the supervision of a central office attached to the metropolitan police, where the register is kept. Some 200 officers in the different gaols throughout the United Kingdom have been instructed in Anthropometry. In Glasgow it is used by the police.

Finger Prints.—In 1823 Purkenje, the eminent physiologist of Breslau, drew attention to the subject of finger impressions. He distinguished nine types, and suggested a system of classification, but it was not followed up. The first practical application of the method was made by Sir William Herschel, of the Indian Civil Service, who introduced it into the district of Hooghly, in Bengal, as a means of identification, to meet the practice of personation prevalent in all the courts. He wrote a report recommending its general adoption in India, but his advice was not followed, and the practice lapsed in the Hooghly district after his departure. The subject was afterwards taken up as an anthropological study by Mr Francis Galton, and very fully worked out. It is thus explained in brief by Mr G. R. Henry, inspector-general of police, Lower Provinces:—

The palmar surface of the hand and the sole of the foot are traversed by innumerable ridges, forming many varieties of pattern, and by creases. The ridge patterns and the ridge characteristics persist throughout the whole period of human life, and are so distinctive as to differentiate each individual from all others. An accurate reproduction of these ridges is obtained by inking the finger bulb and pressing it on paper, the impression thus recorded being a reversal of the pattern on the finger. All impressions may be arranged under one of four types, namely, arches, loops, whorls, composites. Arches subdivide into arches and tented arches; clear definitions demarcate arches from tented arches, and both from loops. Loops may be *ulnar* or *radial*, and are further differentiated from each other by ridge counting and by their ridge characteristics. Whorls are single- or double-cored; impressions of this type differ conspicuously from each other, owing to the innumerable varieties of pattern they present, but further demarcation is provided by ridge tracing. Composites include central pockets, lateral pockets, twinned loops, accidentals.

From this it will be seen that the classification is somewhat complicated and technical. For further explanation and for the practical application of the method the reader is referred to Mr Henry's book on *Finger Prints* (1900).

In 1892 Anthropometry was introduced into Bengal, and then into other provinces; but after some years' experience certain defects in working became apparent, and attention was turned to the alternative use of finger-prints, on which the Home Office, as previously mentioned, had reported favourably in 1894. Experiments in identification by finger-prints only were made in Bengal, and were so successful that in 1897 the government of India appointed a committee to examine both systems. It recommended the adoption of finger-prints on the Bengal plan "as being superior to the anthropometric method—(1) in simplicity of working; (2) in the cost of apparatus; (3) in the fact that all skilled work is transferred to a central or classification office; (4) in the rapidity with which the process can be worked; and (5) in the certainty of the results." Various theoretical objections to finger-prints have been raised, but they have no particular value. Obliteration of the ridges by injury is possible, but it would in itself be suspicious, and would constitute a most distinctive personal mark; obscuration by manual labour is not found to be a serious drawback. In June 1897 a resolution of the governor-general in council directed the adop-

tion of the finger-print system throughout India, and its gradual substitution for the previously existing anthropometric system has since been carried out. Its use is not confined to the police department, but extends to all branches of public business.

It is probable that different systems may suit different conditions. Foreign governments now use for police purposes combinations of Anthropometry and finger-prints similar to that adopted in England. There are minor differences, but the systems are sufficiently alike to be available for dealing with international crime. The full advantage of scientific identification, however, will not be reaped until judicial procedure recognizes more clearly the distinction between professional and accidental criminals. On this point the committee of 1894 remarked:—"As there are some criminals who ought never to be sent to prison, there are others who ought never to be released; and when this distinction is established and provided for by legislation, it will be of even greater importance than at present to have an exact record of each criminal's offences."

LITERATURE.—BERTILLON.—*Instructions Signalétiques*. HENRY.—*Classification and Uses of Finger Prints*. SPEARMAN.—*Fortnightly Review*, March 1890; *New Review*, July 1893. Blue Book.—"Report on best Means available for identifying Habitual Criminals," 1894. (A. S.)

Antibes, a small seaport of France, department of Alpes Maritimes, in the arrondissement of Grasse, 11 miles in direct line S.S.W. of Nice, on the railway from Toulon to Nice. The ramparts are being demolished. A state horticultural college was established in 1891. Industries include perfume distilling. Population (1881), 3810; (1891), 4926; (1896), 4956; (1901), 6600.

Anticosti, a barren island of Quebec, Canada, situated in the northern portion of the Gulf of St Lawrence. It has been converted into an immense preserve for game of all kinds.

Antigo, a city of Wisconsin, U.S.A., the capital of Langlade county, situated in the north-eastern part of the state, on a branch of the Chicago and North-Western railway, at an altitude of 1483 feet. Its industries consist mainly in the manufacture of lumber. Population (1885), 1979; (1895), 5002; (1900), 5145.

Antigua, an island of the British West Indies, the largest member of the outer coralline chain, east of Nevis and north of Montserrat, with an area of 108 square miles. In 1881 the population was 34,000, and in 1891, 36,200, St John, the capital, containing 7938. It forms, with Barbuda and Redonda, one of the five presidencies into which the Leeward group is divided, and is the seat of the general governing body. The local legislative council ceased to send four unofficial members to the Federal Legislative Council in 1898, when the legislature, in consideration of pecuniary assistance from the British Government, passed an act abrogating the semi-elective constitution which had existed since 1866. The island is now, like the other presidencies of the Leeward Islands colony, administered as a Crown Colony, and the legislative council consists of eight official and eight non-official members, all nominated by the governor. Education is by law compulsory, and there are many elementary schools throughout the island. There is a grammar school for boys and one for girls, and the Cambridge local examinations are held annually, as are the examinations of the University of London. Agricultural training is given under the Government at Skerrett's school. The Mico training institution was closed in 1899, and students are now trained in the Mico training college in Jamaica. The Anglican, Wesleyan, and Moravian churches are the

most numerous. There is a small volunteer defence force. The island has direct steam communication with Great Britain, New York, and Canada, and is connected with the West India and Panama Telegraph Company's cable. The decline of the sugar industry has had a serious effect on the prosperity and public finances of the island; and, as in many other West Indian colonies, considerable retrenchments in public expenditure had to be effected during the last few years of the century, which were also marked by hurricane and drought. Sweet potatoes, yams, maize, and guinea-corn are grown for home consumption, and pine-apples are exported to a small extent. The lands were in 1899 classified as follows:—Cultivated in sugar-cane, 14,860 acres; other crops, 1660 acres; pasture, 22,350; uncultivated, 19,910; mountain and waste land, 10,495; total (estimated) 69,275 acres. In 1896 the exports, chiefly cane-sugar and pine-apples, were £131,000; in 1898, £79,000; and in 1899, £121,832. The imports in 1896 were £135,600; in 1898 they fell to £105,000, but in 1899 they showed improvement, standing at £109,031. The revenue in 1899 was £42,822, and the expenditure £51,959. The debt stood at £137,500 in 1900. Trade is chiefly with the United States. The tonnage entered and cleared at the various ports of the island was in 1898—steam, 409,122 (all British); sailing, 20,046 (of which 13,612 was British).

The islands Barbuda (680) and Redonda (120) produce phosphates of alumina.

Antilles, a term of somewhat doubtful origin now generally used, especially by foreign writers, as synonymous with the expression "West India Islands." Like "Brazil," it dates from a period anterior to the discovery of the New World, "Antilia" being one of those mysterious lands of the Gloomy Ocean, which figured on the mediæval charts sometimes as an archipelago, sometimes as continuous land of greater or lesser extent, constantly fluctuating in mid-ocean between the Canaries and East India. But it came at last to be identified with the land discovered by Columbus. Later, when this was found to consist of a vast archipelago enclosing the Caribbean sea and Gulf of Mexico, *Antilia* assumed its present plural form,

Antilles, which was collectively applied to the whole of this archipelago. This theory fails to account for the origin of the term itself, which is supposed by some to be a corrupt form of the still older and more famous *Atlantis*. For the islands and groups now comprised under this designation, see WEST INDIES, and the separate entries—CUBA, JAMAICA, &c.

Antioch, (1) on the Orontes. The modern town, *Antakia*, stands in the north-western quarter of the ancient city, on the left bank of the el-Asi, *Orontes*, on level ground at the foot of the rugged range of Mount Casius. More than half the town was destroyed by an earthquake in 1872, and the houses were rebuilt with material from the old walls. A marshy lake, in the fertile plain to the north, makes the town unhealthy, and the trade, in maize and liquorice root, is small. There is a British vice-consulate. The population consists of Moslems and Ansarieh, 16,000; Christians and Jews, 8000.

(2) **PISIDIAN ANTIOCH** was situated on the lower southern slopes of the Sultan Dagh, about $1\frac{1}{2}$ mile east of Yalovach, in the Konia vilayet of Asia Minor, on the right bank of a stream, ancient *Anthius*, which flows into the Hoiran Geul. It was probably founded, on the site of a Phrygian sanctuary, by Seleucus Nicator, 301-280 B.C., and was made a free city by the Romans in 189 B.C. It was a thoroughly Hellenized, Greek-speaking city, in the midst of a Phrygian people, with a mixed population that included many Jews. Before 6 B.C. Augustus made it a colony with the title *Cæsarea*, and connected it with Lystra by the "Royal Road." Under Claudius A.D. 41-54, when visited by Paul and Barnabas it was the civil and military centre of South Galatia, and a place of importance. In 1097 the Crusaders found rest and shelter within its walls. The ruins are interesting, and show that Antioch was a strongly-fortified city of Hellenic and Roman type (Ramsay, *St. Paul the Traveller: Historical Commentary on the Galatians*, 1899).

Antioquia, a department of the republic of Colombia, bounded on the N. by the Colombian departments of Bolivar and Cauca, on the E. by that of Santander and Boyaca, on the S. by those of Tolima and Cauca, and on the W. by Cauca. It has an area of 22,316 sq. miles, and its population is roughly estimated at about 500,000. The population of the capital, Medellin, is estimated at 40,000. The other principal towns are Marinilla, Sonson, Salamina, Santa Rosa, and Puerto Berrio.

A N T I - S E M I T I S M .

IN the political struggles of the concluding quarter of the 19th century an important part was played by a religious, political, and social agitation against the Jews, known as "Anti-Semitism." The origins of this remarkable movement already threaten to become obscured by legend. The Jews contend that anti-Semitism is a mere atavistic revival of the Jew-hatred of the Middle Ages. The extreme section of the anti-Semites, who have given the movement its quasi-scientific name, declare that it is a racial struggle—an incident of the eternal conflict between Europe and Asia—and that the anti-Semites are engaged in an effort to prevent what is called the Aryan race from being subjugated by a Semitic immigration, and to save Aryan ideals from being modified by an alien and demoralizing oriental *Anschauung*. There is no essential foundation for either of these contentions. Religious prejudices reaching back to the dawn of history have been reawakened by the anti-Semitic agitation, but they did not originate it, and they have not entirely controlled it. The alleged racial divergence is, too, only a linguistic hypothesis on the physical evidence of which anthropologists are not agreed (Topinard, *Anthropologie*, p. 444; Taylor, *Origins of Aryans*, cap. i.), and, even if it were proved,

it has existed in Europe for so many centuries, and so many ethnic modifications have occurred on both sides, that it cannot be accepted as a practical issue. It is true that the ethnographical histories of the Jews and the nations of Europe have proceeded on widely diverging lines, but these lines have more than once crossed each other and become interlaced. Thus Aryan elements are at the beginnings of both; European morals have been ineradicably semitized by Christianity, and the Jews have been Europeans for over a thousand years, during which their character has been modified and in some respects transformed by the ecclesiastical and civil politics of the nations among whom they have made their permanent home. Anti-Semitism is then exclusively a question of European politics, and its origin is to be found, not in the long struggle between Europe and Asia, or between the Church and the Synagogue, which filled so much of ancient and mediæval history, but in the social conditions resulting from the emancipation of the Jews in the middle of the 19th century.

If the emancipated Jews were Europeans in virtue of the antiquity of their western settlements, and of the character impressed upon them by the circumstances of

their European history, they none the less presented the appearance of a strange people to their Gentile fellow-countrymen. They had been secluded in their ghettos for centuries, and had consequently acquired a physical and moral physiognomy differentiating them in a measure from their former oppressors. This peculiar physiognomy was, on its moral side, not essentially Jewish or even Semitic. It was an advanced development of the main attributes of civilized life, to which Christendom in its transition from feudalism had as yet only imperfectly adapted itself. The ghetto, which had been designed as a sort of quarantine to safeguard Christendom against the Jewish heresy, had in fact proved a storage chamber for a portion of the political and social forces which were destined to sweep away the last traces of feudalism from central Europe. In the ghetto, the pastoral Semite, who had been made a wanderer by the destruction of his nationality, was steadily trained, through centuries, to become an urban European, with all the parasitic activities of urban economics, and all the democratic tendencies of occidental industrialism. Excluded from the army, the land, the trade corporations, and the artisan guilds, this quondam oriental peasant was gradually transformed into a commercial middleman and a practised dealer in money. Oppressed by the Church, and persecuted by the State, his theocratic and monarchical traditions lost their hold on his daily life, and he became saturated with a passionate devotion to the ideals of democratic politics. Finally, this former bucolic victim of Phœnician exploitation had his wits preternaturally sharpened, partly by the stress of his struggle for life, and partly by his being compelled in his urban seclusion to seek for recreation in literary exercises, chiefly the subtle dialectics of the Talmudists (Loeb, *Juif de l'Histoire*; Jellinek, *Jüdische Stamm*). Thus, the Jew who emerged from the ghetto was no longer a Palestinian Semite, but an essentially modern European, who differed from his Christian fellow-countrymen only in the circumstances that his religion was of the older Semitic form, and that his physical type had become sharply defined through a slightly more rigid exclusiveness in the matter of marriages than that practised by Protestants and Roman Catholics (Andree, *Volkskunde der Juden*, p. 58).

Unfortunately, these distinctive elements, though not very serious in themselves, became strongly accentuated by concentration. Had it been possible to distribute the emancipated Jews uniformly throughout Christian society, as was the case with other emancipated religious denominations, there would have been no revival of the Jewish question. The Jews, however, through no fault of their own, belonged to only one class in European society—the industrial *bourgeoisie*. Into that class all their strength was thrown, and owing to their ghetto preparation, they rapidly took a leading place in it, politically and socially. When the mid-century revolutions made the *bourgeoisie* the ruling power in Europe, the semblance of a Hebrew domination presented itself. It was the exaggeration of this apparent domination, not by the *bourgeoisie* itself, but by its enemies among the vanquished reactionaries on the one hand, and by the extreme Radicals on the other, which created modern anti-Semitism as a political force.

The movement took its rise in Germany and Austria. Here the concentration of the Jews in one class of the population was aggravated by their excessive numbers. While in France the proportion to the total population was, in the early 'seventies, 0.14 per cent., and in Italy, 0.12 per cent., it was 1.22 per cent. in Germany, and 3.85 per cent. in Austria-Hungary; Berlin had 4.36 per cent. of Jews, and Vienna 6.62 per cent. (Andree, *Volkskunde*, pp. 287, 291, 294, 295). The activity of the Jews

consequently manifested itself in a far more intense form in these countries than elsewhere. This was apparent even before the emancipations of 1848. Towards the middle of the 18th century, a limited number of wealthy Jews had been tolerated as *Schutz-Juden* outside Germany. the ghettos, and their sons, educated as Germans under the influence of Moses Mendelssohn and his school (Jews, MODERN, *Ency. Brit.* xiii. p. 680), supplied a majority of the leading spirits of the revolutionary agitation. To this period belong the formidable names of Ludwig Boerne (1786-1837), Heinrich Heine (1799-1854), Edward Gantz (1798-1839), Gabriel Riesser (1806-1863), Ferdinand Lassalle (1825-1864), Karl Marx (1818-1883), Moses Hess (1812-1875), Ignatz Kuranda (1811-1884), and Johann Jacoby (1805-1877). When the revolution was completed, and the Jews entered in a body the national life of Germany and Austria, they sustained this high average in all the intellectual branches of middle-class activity. Here again, owing to the accidents of their history, a further concentration became apparent. Their activity was almost exclusively intellectual. The bulk of them flocked to the financial and the distributive (as distinct from the productive) fields of industry to which they had been confined in the ghettos. The sharpened faculties of the younger generation at the same time carried everything before them in the schools, with the result that they soon crowded the professions, especially medicine, law, and journalism (Nossig, *Statistik des Jüd. Stammes*, pp. 33-37; Jacobs, *Jew. Statistics*, pp. 41-69). Thus the "Semitic domination," as it was afterwards called, became every day more strongly accentuated. If it was a long time in exciting resentment and jealousy, the reason was that it was in no sense alien to the new conditions of the national life. The competition was a fair one. The Jews might be more successful than their Christian fellow-citizens, but it was in virtue of qualities which complied with the national standards of conduct. They were as law-abiding and patriotic as they were intelligent. Crime among them was far below the average (Nossig, p. 31). Their complete assimilation of the national spirit was brilliantly illustrated by the achievements in German literature, art, and science of such men as Heinrich Heine and Berthold Auerbach (1812-1882), Felix Mendelssohn (1809-1847), and Jacob Meyerbeer (1794-1864), Jacoby the mathematician (1804-1851), Valentin the physiologist (1808-1883), and Lazarus (b. 1824) and Steinthal (1823-1892) the national psychologists. In politics, too, Edward Lasker (1829-1884) and Ludwig Bamberger (b. 1823) had shown how Jews could put their country before party, when, at the turning-point of German Imperial history in 1866, they led the secession from the *Fortschritts-Partei* and founded the National Liberal party, which enabled Prince Bismarck to accomplish German unity. Even their financiers were not behind their Christian fellow-citizens in patriotism. Prince Bismarck himself confessed that the money for carrying on the 1866 campaign was obtained from the Jewish banker Bleichroeder, in face of the refusal of the money-market to support the war. Hence the voice of the old Jew-hatred—for in a weak way it was still occasionally heard in obscurantist corners—was shamed into silence, and it was only in the European twilight—in Russia and Rumania—and in lands where mediævalism still lingered, such as northern Africa and Persia, that oppression and persecution continued to dog the steps of the Jews.

The signal for the change came in 1873, and was given unconsciously by one of the most distinguished Jews of his time, Edward Lasker, the gifted lieutenant of Bismarck in the leadership of the National Liberal party. The unification of Germany in 1870, and the

rapid payment of the enormous French War indemnity, had given an unprecedented impulse to industrial and financial activity throughout the empire. Money became cheap and speculation became universal. A company mania set in which was favoured by the Government, who granted railway and other concessions with a prodigal hand. The inevitable result of this state of things was first indicated by Jewish politicians and economists. On the 14th January 1873, Edward Lasker called the attention of the Prussian Diet to the dangers of the situation, while his colleague, Ludwig Bamberger, in an able article in the *Preussischen Jahrbücher*, condemned the policy which had permitted the milliards to glut the country instead of being paid on a plan which would have facilitated their gradual digestion by the economic machinery of the nation. Deeply impressed by the gravity of the impending crisis, Lasker instituted a searching inquiry, with the result that he discovered a series of grave company scandals in which financial promoters and aristocratic directors were chiefly involved. Undeterred by the fact that the leading spirit in these abuses, Bethel Henry Strousberg, was a Jew, Lasker presented the results of his inquiry to the Diet on the 7th February 1873, in a speech of great power and full of sensational disclosures. The dramatic results of this speech need not be dwelt upon here (for details see Blum, *Deutsche Reich zur Zeit Bismarcks*, pp. 153-181). It must suffice to say that in the following May the great Vienna "Krach" occurred, and the colossal bubble of speculation burst, bringing with it all the ruin foretold by Lasker and Bamberger. From the position occupied by the Jews in the commercial class, and especially in the financial section of that class, it was inevitable that a considerable number of them should figure in the scandals which followed. At this moment an obscure Hamburg journalist, Wilhelm Marr, who as far back as 1862 had printed a still-born tract against the Jews (*Judenspiegel*), published a sensational pamphlet entitled *Der Sieg des Judenthums über das Germanenthum* ("The Victory of Judaism over Germanism"). The book fell upon fruitful soil. It applied to the nascent controversy a theory of nationality which, under the great sponsorship of Hegel, had seized on the minds of the German youth, and to which the stirring events of 1870 had already given a deep practical significance. The state, according to the Hegelians, should be national, and the nation should be a unit comprising individuals speaking the same language and of the same racial origin. Heterogeneous elements might be absorbed, but if they could not be reduced to the national type they should be eliminated. This was the pseudo-scientific note of the new anti-Semitism, the theory which differentiated it from the old religious Jew-hatred and sought to give it a rational place in modern thought. Marr's pamphlet, which reviewed the facts of the Jewish social concentration without noticing their essentially transitional character, proved the pioneer of this teaching. It was, however, in the passions of party politics that the new crusade found its chief sources of vitality. The enemies of the *bourgeoisie* at once saw that the movement was calculated to discredit and weaken the school of Manchester Liberalism, then in the ascendant. Agrarian capitalism, which had been dethroned by industrial capitalism in 1848, and had burnt its fingers in 1873, seized the opportunity of paying off old scores. The clericals, smarting under the *Kulturkampf*, which was supported by the whole body of Jewish liberalism, joined heartily in the new cry. In 1876 another sensational pamphlet was published, Otto Glagau's *Der Boersen und Grundergeschwindel in Berlin* ("The Bourses and the Company Swindles in Berlin"),

dealing in detail with the Jewish participation in the scandals first revealed by Lasker. The agitation gradually swelled, its growth being helped by the sensitiveness and *cacoëthes scribendi* of the Jews themselves, who contributed two pamphlets and a much larger proportion of newspaper articles for every one supplied by their opponents (Jacobs, *Bibliog. Jew. Question*, p. xi.). Up to 1879, however, it was more of a literary than a political agitation, and was generally regarded only as an ephemeral craze or a passing spasm of popular passion.

Towards the end of 1879 it spread with sudden fury over the whole of Germany. This outburst, at a moment when no new financial scandals or other illustrations of Semitic demoralization and domination were before the public, has never been fully explained. It is impossible to doubt, however, that the secret springs of the new agitation were more or less directly supplied by Prince Bismarck himself. Since 1877 the relations between the chancellor and the National Liberals had gradually become strained. The deficit in the budget had compelled the Government to think of new taxes, and in order to carry them through the Reichstag the support of the National Liberals had been solicited. Until then the National Liberals had faithfully supported the chancellor in nursing the consolidation of the new empire, but the great dream of its leaders, especially of Lasker and Bamberger, who had learnt their politics in England, was to obtain a constitutional and economic *régime* similar to that of the British Isles. The organization of German unity was now completed, and they regarded the new overtures of Prince Bismarck as an opportunity for pressing their constitutional demands. These were refused, the Reichstag was dissolved, and Prince Bismarck boldly came forward with a new fiscal policy, a combination of protection and state socialism. Lasker and Bamberger thereupon led a powerful secession of National Liberals into opposition, and the chancellor was compelled to seek a new majority among the ultra-Conservatives and the Roman Catholic Centre. This was the beginning of the famous "journey to Canossa." Bismarck did not hide his mortification. He began to recognize in anti-Semitism a means of "dishing" the Judaized liberals, and to his creatures who assisted him in his press campaigns he dropped significant hints in this sense (Busch, *Bismarck*, ii. 453-54, iii. 16). He even spoke of a new *Kulturkampf* against the Jews (*ibid.* ii. p. 484). How these hints were acted upon has not been revealed, but it is sufficiently instructive to notice that the final breach with the National Liberals took place in July 1879, and that it was immediately followed by a violent revival of the anti-Semitic agitation. Marr's pamphlet was reprinted, and within a few months ran through nine further editions. The historian Treitschke gave the sanction of his great name to the movement. The Conservative and Ultramontane press rang with the sins of the Jews. In October an anti-Semitic league was founded in Berlin and Dresden (for statutes of the league see *Nineteenth Century*, February 1881, p. 344).

The leadership of the agitation was now definitely assumed by a man who combined with social influence, oratorical power, and inexhaustible energy, a definite scheme of social regeneration and an organization for carrying it out. This man was Adolf Stoecker (b. 1835), one of the Court Preachers. He had embraced the doctrines of Christian Socialism which the Roman Catholics, under the guidance of Archbishop Ketteler, had adopted from the teachings of the Jew Lassalle (Nitti, *Catholic Socialism*, pp. 94-96, 122, 127), and he had formed a society called "The Christian Social Working-man's Union." He was also a conspicuous member of the Prussian Diet, where he sat and voted with the Conserva-

tives. He found himself in strong sympathy with Prince Bismarck's new economic policy, which, although also of Lassallian origin (Kohut, *Ferdinand Lassalle*, pp. 144 *et seq.*), was claimed by its author as being essentially Christian (Busch, p. 483). Under his auspices the years 1880-81 became a period of bitter and scandalous conflict with the Jews. The Conservatives supported him, partly to satisfy their old grudges against the Liberal *bourgeoisie* and partly because Christian Socialism, with its anti-Semitic appeal to ignorant prejudice, was likely to weaken the hold of the Social Democrats on the lower classes. The Lutheran clergy followed suit, in order to prevent the Roman Catholics from obtaining a monopoly of Christian Socialism, while the Ultramontanes readily adopted anti-Semitism, partly to maintain their monopoly, and partly to avenge themselves on the Jewish and Liberal supporters of the *Kulturkampf*. In this way a formidable body of public opinion was recruited for the anti-Semites. Violent debates took place in the Prussian Diet. A petition to exclude the Jews from the national schools and universities and to disable them from holding public appointments was presented to Prince Bismarck. Jews were boycotted and insulted. Duels between Jews and anti-Semites, many of them fatal, became of daily occurrence. Even unruly demonstrations and street riots were reported. Pamphlets attacking every phase and aspect of Jewish life streamed by the hundred from the printing-press. On their side the Jews did not want for friends, and it was owing to the strong attitude adopted by the Liberals that the agitation failed to secure legislative fruition. The crown prince (afterwards Emperor Frederick) and crown princess boldly set themselves at the head of the party of protest. The crown prince publicly declared that the agitation was "a shame and a disgrace to Germany." A manifesto denouncing the movement as a blot on German culture, a danger to German unity, and a flagrant injustice to the Jews themselves, was signed by a long list of illustrious men, including Herr von Forckenbeck, Professors Mommsen, Gneist, Droysen, Virchow, and Dr Werner Siemens (*Times*, Nov. 18, 1880). During the Reichstag elections of 1881 the agitation played an active part, but without much effect, although Stoecker was elected. This was due to the fact that the great Conservative parties, so far as their political organizations were concerned, still remained chary of publicly identifying themselves with a movement which, in its essence, was of socialistic tendency. Hence the electoral returns of that year supplied no sure guide to the strength of anti-Semitic convictions among the German people.

The first severe blow suffered by the German anti-Semites was in 1882, when, to the indignation of the whole civilized world, the barbarous riots against the Jews in Russia and the revival of the mediæval Blood Accusation in Hungary (see *infra*) illustrated the liability of unreasoning mobs to carry into violent practice the incendiary doctrines of the new Jew-haters. From this blow anti-Semitism might have recovered had it not been for the divisions and scandals in its own ranks, and the artificial forms it subsequently assumed through factitious alliances with political parties bent less on persecuting the Jews than on profiting by the anti-Jewish agitation. The divisions showed themselves at the first attempt to form a political party on an anti-Semitic basis. Imperceptibly the agitators had grouped themselves into two classes, economic and ethnological anti-Semites. The impracticable racial views of Marr and Treitschke had not found favour with Stoecker and the Christian Socialists. They were disposed to leave the Jews in peace so long as they behaved themselves properly, and although they carried on their agitation against Jewish

malpractices in a comprehensive form which seemed superficially to identify them with the root-and-branch anti-Semites, they were in reality not inclined to accept the racial theory with its scheme of revived Jewish disabilities (Huret, *La Question Sociale*—interview with Stoecker). This feeling was strengthened by a tendency on the part of an extreme wing of the racial anti-Semites to extend their campaign against Judaism to its offspring, Christianity. In 1879 Professor Sepp, arguing that Jesus was of no human race, had proposed that Christianity should reject the Hebrew Scriptures and seek a fresh historical basis in the cuneiform inscriptions. Later Dr Dühring, in several brochures, notably *Die Judenfrage als Racen, Sitten und Cultur Frage* (1881), had attacked Christianity as a manifestation of the Semitic spirit which was not compatible with the theological and ethical conceptions of the Scandinavian peoples. The philosopher Friedrich Nietzsche had also adopted the same view without noticing that it was a *reductio ad absurdum* of the whole agitation. (*Menschliches, Allzumenschliches* (1878), *Jenseits von Gut und Böse* (1886), *Genealogie der Moral* (1887).) With these tendencies the Christian Socialists could have no sympathy, and the consequence was that when in March 1881 a political organization of anti-Semitism was attempted, two rival bodies were created, the "Deutsche Volksverein," under the Conservative auspices of Herr Liebermann von Sonnenberg (b. 1848) and Herr Foerster, and the "Sociale Reichsverein," led by the racial and Radical anti-Semites, Ernst Henrici (b. 1854) and Otto Boeckl (b. 1859). In 1886, at an anti-Semitic congress held at Cassel a reunion was effected under the name of the "Deutsche antisemitische Verein," but this only lasted three years. In June 1889 the anti-Semitic Christian Socialists under Stoecker again seceded.

Meanwhile racial anti-Semitism with its wholesale radical proposals had been making considerable progress among the ignorant lower classes. It adapted itself better to popular passions and inherited prejudice than the more academic conceptions of the Christian Socialists. The latter, too, were largely Conservatives, and their points of contact with the proletariat were at best artificial. Among the Hessian peasantry the inflammatory appeals of Boeckl secured many adherents. This paved the way for a new anti-Semitic leader, Herrmann Ahlwardt (b. 1846), who, towards the end of the 'eighties, eclipsed all the other anti-Semites by the sensationalism and violence with which he prosecuted the campaign. Ahlwardt was a person of evil notoriety. He was loaded with debt. In the Manché decoration scandals it was proved that he had acted first as a corrupt intermediary and afterwards as the betrayer of his confederates. His anti-Semitism was adopted originally as a means of *chantage*, and it was only when it failed to yield profit in this form that he came out boldly as an agitator. The wildness, unscrupulousness, and full-bloodedness of his propaganda enchanted the mob, and he bid fair to become a powerful democratic leader. His pamphlets, full of scandalous revelations of alleged malpractices of eminent Jews, were read with avidity. No fewer than ten of them were written and published during 1892. Over and over again he was prosecuted for libel and convicted, but this seemed only to strengthen his influence with his followers. The Roman Catholic clergy and newspapers helped to inflame the popular passions. The result was that anti-Jewish riots broke out. At Neustettin the Jewish synagogue was burnt, and at Xanton the Blood Accusation was revived, and a Jewish butcher was tried on the ancient charge of murdering a Christian child for ritual purposes. The man was, of course, acquitted, but the symptoms it revealed of reviving mediævalism strongly stirred the liberal and cultured mind of Germany. All protest,

however, seemed powerless, and the barbarian movement appeared destined to carry everything before it.

German politics at this moment were in a very intricate state. Prince Bismarck had retired, and Count Caprivi, with a programme of general conciliation based on Liberal principles, was in power. Alarmed by the non-renewal of the anti-Socialist law, and by the conclusion of commercial treaties which made great concessions to German industry, the landed gentry and the Conservative party became alienated from the new chancellor. In January 1892 the split was completed by the withdrawal by the Government of the Primary Education Bill, which had been designed to place primary instruction on a religious basis. The Conservatives saw their opportunity of posing as the party of Christianity against the Liberals and Socialists, who had wrecked the Bill, and they began to look towards Ahlwardt as a possible ally. He had the advantages over Stoecker that he was not a Socialist, and that he was prepared to lead his apparently large following to assist the agrarian movement and weaken the Social Democrats. The intrigue gradually came to light. Towards the end of the year Herr Liebknecht, the Social Democratic leader, denounced the Conservatives to the Reichstag as being concerned "in using the anti-Semitic movement as a bastard edition of Socialism for the use of stupid people" (1st December). Two days later the charge was confirmed. At a meeting of the party held on 3rd December the following plank was added to the Conservative programme: "We combat the oppressive and disintegrating Jewish influence on our national life; we demand for our Christian people a Christian magistracy and Christian teachers for Christian pupils; we repudiate the excesses of anti-Semitism." In pursuance of this resolution Ahlwardt was returned to the Reichstag at a by-election by the Conservative district of Arnswalde-Friedeberg. The coalition was, however, not yet completed. The intransigent Conservatives, led by Baron von Hammerstein, the editor of the *Kreuz-Zeitung*, justly felt that the concluding sentence of the resolution of 3rd December repudiating "the excesses of anti-Semitism" was calculated to hinder a full and loyal co-operation between the two parties. Accordingly on 9th December another meeting of the party was summoned. Twelve hundred members met at the Tivoli Hall in Berlin, and with only seven dissentients solemnly expunged the offending sentence from the resolution. The history of political parties may be searched in vain for a parallel to this discreditable transaction.

The capture of the Conservative party proved the high-water mark of German anti-Semitism. From that moment the tide began to recede. All that was best in German national life was scandalized by the cynical tactics of the Conservatives. The emperor, strong Christian though he was, was shocked at the idea of serving Christianity by a compact with unscrupulous demagogues and ignorant fanatics. Prince Bismarck growled out a stinging sarcasm from his retreat at Friedrichsruh. Even Stoecker raised his voice in protest against the "Ahlwardtism" and "Boeckelianism," and called upon his Conservative colleagues to distinguish between "respectable and disreputable anti-Semitism." As for the Liberals and Socialists, they filled the air with bitter laughter, and declared from the housetops that the stupid party had at last been overwhelmed by its own stupidity. The Conservatives began to suspect that they had made a false step, and they were confirmed in this belief by the conduct of their new ally in the Reichstag. His debut in parliament was the signal for a succession of disgraceful scenes. His whole campaign of calumny was transferred to the floor of the house, and for some weeks the Reichstag discussed little else than his so-called revela-

tions. The Conservatives listened to his wild charges in uncomfortable silence, and refused to support him. Stoecker opposed him in a violent speech. The Radicals and Socialists, taking an accurate measure of the shallow vanity of the man, adopted the policy of giving him "enough rope." Shortly after his election he was condemned to five months' imprisonment for libel, and he would have been arrested but for the interposition of the Socialist party, including five Jews, who claimed for him the immunities of a member of parliament. When he moved for a commission to inquire into his revelations, it was again the Socialist party which supported him, with the result that all his charges, without exception, were found to be absolutely baseless. Ahlwardt was covered with ridicule, and when in May the Reichstag was dissolved, he was marched off to prison to undergo the sentence for libel from which his parliamentary privilege had up to that moment protected him.

His hold on the anti-Semitic populace was, however, not diminished. On the contrary, the action of the Conservatives at the Tivoli Congress could not be at once eradicated from the minds of the Conservative voters, and when the electoral campaign began it was found impossible to explain to them that the party leaders had changed their minds. The result was that Ahlwardt, although in prison, was elected by two constituencies. At Arnswalde-Friedeberg he was returned in the teeth of the opposition of the official Conservatives, and at Neu-Stettin he defeated no less a person than his anti-Semitic opponent Stoecker. Seventeen other anti-Semites, all of the Ahlwardtian school, were elected. This, however, represented the extreme strength of the anti-Semitic party in Germany; for henceforth it had to stand alone as one of the many minor factions in the Reichstag, avoided by all the great parties, and too weak to exercise any influence on the main course of affairs.

During the subsequent seven years it became more and more discredited. The financial scandals connected with Foerster's attempt to found a Christian Socialist colony in Paraguay, the conviction of Baron von Hammerstein, the anti-Semitic Conservative leader, of forgery and swindling (1895-96), and several minor scandals of the same unsavoury character, covered the party with the very obloquy which it had attempted to attach to the Jews. At the same time the Christian Socialists who had remained with the Conservative party also suffered. After the elections of 1893, Stoecker was dismissed from his post of Court Preacher, and publicly reprimanded for speaking familiarly of the empress. Two years later the Christian Socialist Pastor Neumann, observing the tendency of the Conservatives to coalesce with the moderate Liberals in antagonism to Social Democracy, declared against the Conservative party. The following year the emperor publicly condemned Christian Socialism and the "political pastors," and Stoecker was expelled from the Conservative party for refusing to modify the socialistic propaganda of his organ, *Das Volk*. His fall was completed by a quarrel with the Evangelical Social Union. He left the Union and appealed to the Lutheran clergy to found a new Church social organization, but met with no response. Another blow to anti-Semitism came from the Roman Catholics. They had become alarmed by the unbridled violence of the Ahlwardtians, and when in 1894 Foerster declared in an address to the German anti-Semitic Union that anarchical outrages like the murder of President Carnot were as much due to the "Anarchismus von oben" as the "Anarchismus von unten," the Ultramontane *Germania* publicly washed its hands of the Jew-baiters (1st July 1894). Thus gradually German anti-Semitism became stripped of every adventitious alliance;

and although at the general election of 1898 it managed still to return twelve members to the Reichstag, it had ceased to be regarded as a serious element in politics.

The causes of the decline of German anti-Semitism are not difficult to determine. While it remained a theory of nationality and a fad of the metaphysicians, it made considerable noise in the world, but without exercising much practical influence. When it attempted to play an active part in politics it became submerged by the ignorant and superstitious voters, who could not understand its scientific justification, but who were quite ready to declaim and riot against the Jew bogey. It thus became a sort of *Jacquerie* which, being exploited by unscrupulous demagogues, soon alienated all its respectable elements. Its moments of real importance were due not to inherent strength but to the uses made of it by other political parties for their own purposes. These coalitions are no longer possible, not only because anti-Semitism has ceased to be respectable, but because, in face of the growing strength of Democratic Socialism, all supporters of the present organization of society have found it necessary to sink their differences. The new social struggle has eclipsed the racial theory of nationality. The Social Democrat is now the enemy, and the new reaction counts on the support of the rich Jews and the strongly individualist Jewish middle class to assist it in preserving the existing social structure.

More serious have been the effects of German anti-Semitic teachings on the political and social life of the countries adjacent to the empire—Russia, Austria, and France. In Russia these effects were first seriously felt owing to the fury of autocratic reaction to which the tragic death of the Tsar Alexander II. gave rise. This, however, like the Strousberg *Krach* in Germany, was only the proximate cause of the outbreak. There were other elements which had created a *milieu* peculiarly favourable to the transplantation of the German craze. In

Russia. the first place the mediæval anti-Semitism was still an integral part of the polity of the empire. The Jews were cooped up in one huge ghetto in the western provinces, "marked out to all their fellow-countrymen as aliens and a pariah caste set apart for special and degrading treatment" (*Persecution of the Jews in Russia*, 1891, p. 5). In the next place, owing to the emancipation of the serfs which had half ruined the land-owners, while creating a free but moneyless peasantry, the Jews, who could be neither nobles nor peasants, had found a vocation as money-lenders and as middlemen between the grain producers and the grain consumers and exporters. There is no evidence that this function was performed, as a rule, in an exorbitant or oppressive way. On the contrary, the fall in the value of cereals on all the provincial markets, after the riots of 1881, shows that the Jewish competition had previously assured full prices to the farmers (Schwabacher, *Denkschrift*, 1882, p. 27). Nevertheless, the Jewish activity or "exploitation," as it was called, was resented, and the ill-feeling it caused among land-owners and farmers was shared by non-Jewish middlemen and merchants who had thereby been compelled to be satisfied with small profits. Still there was but little thought of seeking a remedy in an organized anti-Jewish movement. On the contrary, the abnormal situation aggravated by the disappointments and depression caused by the Turkish war, had stimulated a widespread demand for constitutional changes which would enable the people to adopt a state-machinery more exactly suited to their needs. Among the peasantry this demand was promoted and fomented by the Nihilists, and among the land-owners it was largely adopted as a means of checking what threatened to become a new *Jacquerie* (Walcker, *Gegenwärtige Lage Russlands*,

1873; *Innere Krisis Russlands*, 1876). The tsar, Alexander II., strongly sympathized with this movement, and on the advice of Count Loris Melikoff and the council of ministers a rudimentary scheme of parliamentary government had been drafted and actually signed when the emperor was assassinated. Meanwhile a nationalist and reactionary agitation, originating like its German analogue in the Hegelianism of a section of the lettered public, had manifested itself in Moscow. After some early vicissitudes, it had been organized, under the auspices of Alexis Kireieff, Chomjakoff, Aksakoff, and Kocheleff, into the Slavophil party, with a Romanticist programme of reforms based on the old traditions of the pre-Petrine epoch. This party gave a great impetus to Slav nationalism. Its final possibilities were sanguinarily illustrated by Muravieff's campaign in Poland in 1863, and in the war against Turkey in 1877, which was exclusively its handiwork (Statement by General Kireieff: Schütz, *Das heutige Russland*, p. 104). After the assassination of Alexander II. the Slavophil teaching, as expounded by Ignatieff and Pobyedonostzeff, became paramount in the Government, and the new tsar was persuaded to cancel the constitutional project of his father. The more liberal views of a section of the Slavophiles under Aksakoff, who had been in favour of representative institutions on traditional lines, were displaced by the reactionary system of Pobyedonostzeff, who took his stand on absolutism, orthodoxy, and the racial unity of the Russian people. This was the situation on the eve of Easter 1881. The hardening nationalism above, the increasing discontent below, the economic activity of the Hebrew heretics and aliens, and the echoes of anti-Semitism from over the western border were combining for an explosion.

A scuffle in a tavern at Elisabethgrad, in Kherson, sufficed to ignite this combustible material. The scuffle grew into a riot, the tavern was sacked, and the drunken mob, hounded on by agitators, who declared that the Jews were using Christian blood for the manufacture of their Easter bread, attacked and looted the Jewish quarter. The outbreak rapidly spread. On 7th May there was a similar riot at Smiela, near Czergassy, and the following day there was a violent outbreak at Kieff, which left 2000 Jews homeless. Within a few weeks the whole of Western Russia, from the Black Sea to the Baltic, was smoking with the ruins of Jewish homes. Scores of Jewish women were dishonoured, hundreds of men, women, and children were slaughtered, and tens of thousands were reduced to beggary and left without a shelter. Murderous riots or incendiary outrages took place in no fewer than 167 towns and villages, including Warsaw, Odessa, and Kieff. Europe had witnessed no such scenes of mob savagery since the Black Death massacres in the fourteenth century. As the facts gradually filtered through to the western capitals, they caused a thrill of horror everywhere. An indignation meeting held at the Mansion House in London, under the presidency of the Lord Mayor, was the signal for a long series of popular demonstrations condemning the persecutions, held in most of the chief cities of England and the Continent.

Except as stimulated by the Judeophobe revival in Germany the Russian outbreak in its earlier forms does not belong specifically to modern anti-Semitism. It was essentially a mediæval uprising animated by the religious fanaticism, gross superstition, and predatory instincts of a people still in the mediæval stage of their development. This is proved by the fact that, although the Russian peasant was supposed to be a victim of unbearable Jewish "exploitation," he was not moved to riot until he had been brutalized by drink and excited by the old fable of the Blood Accusation. The modern anti-Semitic element came

from above, and followed closely on the heels of the riots. It has been freely charged against the Russian Government that it promoted the riots in 1881 in order to distract popular attention from the Nihilist propaganda and from the political disappointments involved in the cancellation of the previous tsar's constitutional project (Lazare, *L'Antisémitisme*, p. 211). This is an hypothesis which will not stand the test of investigation. It is true that the local authorities, both civil and military, favoured the outbreak, and took no steps to suppress it, but this may be accounted for by the fact that the feudal bureaucracy had just escaped a great danger, and were consequently not sorry to see the discontented populace venting their passions on the Jews. In the higher circles of the Government different views prevailed. The tsar himself was at first persuaded that the riots were the work of Nihilists, and he publicly promised his protection to the Jews. On the other hand, his ministers, ardent Slavophiles, thought they recognized in the outbreak an endorsement of the nationalist teaching of which they were the apostles, and, while reprobating the acts of violence, came to the conclusion that the most reasonable solution was to aggravate the legal disabilities of the persecuted aliens and heretics. To this view the tsar was won over, partly by the clamorous indignation of Western Europe, which had wounded his national *amour propre* to the quick, and partly by the strongly partisan report of a commission appointed to inquire, not into the administrative breakdown which had allowed riot to run loose over the western and southern provinces, but into the "exploitation" alleged against the Jews, the reasons why "the former laws limiting the rights of the Jews" had been mitigated, and how these laws could be altered so as "to stop the pernicious conduct of the Jews" (Rescript of 3rd September 1881). The result of this report was the drafting of a "Temporary Order concerning the Jews" by the Minister of the Interior, Count Ignatieff, which received the assent of the tsar on the 3rd May 1882. This order, which was so little temporary that it has not yet been repealed, had the effect of creating a number of fresh ghettos within the pale of Jewish settlement. The Jews were cooped up within the towns, and their rural interests were arbitrarily confiscated. The doubtful incidence of the order gave rise to a number of judgments of the Senate, by which all its persecuting possibilities were brought out, with the result that the activities of the Jews were completely paralysed, and they became a prey to unparalleled cruelty. As the gruesome effect of this legislation became known, a fresh outburst of horror and indignation swelled up from Western Europe. It proved powerless. Count Ignatieff was dismissed owing to the protests of high-placed Russians, who were disgusted by the new *Kulturkampf*, but his work remained, and, under the influence of M. Pobyedonostzeff, the Procurator of the Holy Synod, the policy of the "May Laws," as they were significantly called, was applied to every aspect of Jewish life with pitiless rigour. The temper of the tsar may be judged by the fact that when an appeal for mercy from an illustrious personage in England was conveyed to him at Fredensborg through the gracious medium of the tsaritzza, his Majesty angrily exclaimed within the hearing of an Englishman in the ante-room who was the bearer of the message, "Never let me hear you mention the name of that people again!"

The Russian May Laws are the most conspicuous legislative monument achieved by modern anti-Semitism. It is true that they re-enacted regulations which resemble the oppressive statutes introduced into Poland through the influence of the Jesuits in the 16th century (Sternberg, *Gesch. d. Juden in Polen*, pp. 141 et seq.), but their

orthodox authors were as little conscious of this irony of history as they were of the Teutonic origins of the whole Slavophil movement. These laws are an experimental application of the political principles extracted by Marr and his German disciples from the metaphysics of Hegel, and as such they afford a valuable means of testing the practical operation of modern anti-Semitism. Their result was a widespread commercial depression which was felt all over the empire. Even before the May Laws were definitely promulgated the passport registers showed that the anti-Semitic movement had driven 67,900 Jews across the frontier, and it was estimated that they had taken with them 13,000,000 roubles, representing a minimum loss of 60,000,000 roubles to the annual turnover of the country's trade. Towards the end of 1882 it was calculated that the agitation had cost Russia as much as the whole Turkish war of 1877. Trade was everywhere paralysed. The enormous increase of bankruptcies, the transfer of investments to foreign funds, the consequent fall in the value of the rouble and the prices of Russian stocks, the suspension of farming operations owing to advances on growing crops being no longer available, the rise in the prices of the necessaries of life, and lastly, the appearance of famine, filled half the empire with gloom. Banks closed their doors, and the great provincial fairs proved failures. When it was proposed to expel the Jews from Moscow there was a loud outcry all over the Sacred City, and even the Orthodox merchants, realizing that the measure would ruin their flourishing trade with the south and west, petitioned against it. The Moscow Exhibition proved a failure. Nevertheless the Government persisted with its harsh policy, and Jewish refugees streamed by tens of thousands across the western frontier to seek an asylum in other lands. In 1891 the alarm caused by this emigration led to further protests from abroad. The citizens of London again assembled at Guildhall, and addressed a petition to the tsar on behalf of his Hebrew subjects. It was handed back to the Lord Mayor by the Russian Ambassador, with a curt intimation that the emperor declined to receive it. At the same time orders were defiantly given that the May Laws should be strictly enforced. Meanwhile the Russian Minister of Finance was at his wits' ends for money. Negotiations for a large loan had been entered upon with the house of Rothschild, and a preliminary contract had been signed, when, at the instance of the London firm, M. Wyshnigradski, the Finance Minister, was informed that unless the persecutions of the Jews were stopped the great banking-house would be compelled to withdraw from the operation. Deeply mortified by this attempt to deal with him *de puissance à puissance*, the tsar peremptorily broke off the negotiations, and ordered that overtures should be made to a non-Jewish French syndicate. In this way anti-Semitism, which had already so profoundly influenced the domestic politics of Europe, set its mark on the international relations of the Powers, for it was the urgent need of the Russian Treasury quite as much as the termination of Prince Bismarck's secret treaty of mutual neutrality which brought about the Franco-Russian alliance (Daudet, *Hist. Dipl. de l'Alliance Franco-Russe*, pp. 259 et seq.).

For nearly three years more the persecutions continued. Elated by the success of his crusade against the Jews, M. Pobyedonostzeff extended his persecuting policy to other non-Orthodox denominations. The legislation against the Protestant Stundists became almost as unbearable as that imposed on the Jews. In the report of the Holy Synod, presented to the tsar towards the end of 1893, the procurator called for repressive measures against Roman

Catholics, Moslems, and Buddhists, and denounced the rationalist tendency of the whole system of secular education in the empire (*Neue Freie Presse*, 31st January 1894). A year later, however, the tsar died, and his successor, without repealing any of the persecuting laws, let it gradually be understood that their rigorous application might be mitigated. The country was tired and exhausted by the persecution, and the tolerant hints which came from high quarters were acted upon with significant alacrity. This tolerant tendency has since been strengthened by a new political movement, inaugurated by Prince Oukhtomsky, the apostle of Russian Asiatic Imperialism. The Prince dreams of a future when the tsar will rule over the whole of Asia, but he realizes that this mission must be based on the most generous principles of religious toleration (Leger, *Russes et Slaves* 3^{me} Série, pp. 79-81). As a personal friend of the new tsar his teachings in this sense have produced considerable effect throughout Russian society, and have helped to mitigate the terrible lot of the Jews.

The only other country in Europe in which a legalized anti-Semitism exists is Rumania. The conditions are very similar to those which obtain in Russia, with the important difference that Rumania is a constitutional country, and that the Jewish persecutions are the work of the elected deputies of the nation. Like the *Bourgeois Gentilhomme* who wrote prose all his life without knowing it, the Rumanians practised the nationalist doctrines of the Hegelian anti-Semites unconsciously long before they were formulated in Germany. In the old days of Turkish domination the lot of the Rumanian Jews was not conspicuously unhappy. It was only when the nation began to be emancipated, and the struggle in the East assumed the form of a crusade against Islam that the Jews were persecuted. Rumanian politicians preached a nationalism limited exclusively to indigenous Christians, and they were strongly supported by all who felt the commercial competition of the Jews.

Rumania. Thus, although the Jews had been settled in the land for many centuries they were by law declared aliens. This was done in defiance of the Treaty of Paris of 1856 and the Convention of 1858 which declared all Rumans to be equal before the law. Under the influence of this distinction the Jews became persecuted, and sanguinary riots were of frequent occurrence. The realization of a Jewish question led to legislation imposing disabilities on the Jews. In 1878 the Berlin Congress agreed to recognize the independence of Rumania on condition that all religious disabilities were removed. Rumania agreed to this condition, but ultimately persuaded the Powers to allow her to carry out the emancipation of the Jews gradually. During the years which have elapsed since then, the condition of the Jews has been in no way improved. Their emancipation is as far off as ever, and their disabilities are heavier than those of their brethren in Russia. For this state of things the example of the anti-Semites in Germany, Russia, Austria, and France is largely to blame, since it has justified the intolerance of the Rumans. Owing, also, to the fact that of late years Rumania has become a sort of *annexe* of the Triple Alliance, it has been found impossible to induce the signatories of the Berlin Treaty to take action to compel the state to fulfil its obligations under that treaty.

In Austria-Hungary the anti-Semitic impulses came almost simultaneously from the North and East. Already in the 'seventies the doctrinaire anti-Semitism of Berlin had found an echo in Budapest. Two members of the Diet, Victor Istoczy and Geza Onody, together with a publicist named Georg Marczianyi, busied themselves in making known the doctrine of Marr in Hungary.

Marczianyi, who translated the German Judeophobe pamphlets into Magyar, and the Magyar works of Onody into German, was the chief medium between the northern and southern schools. In 1880 Istoczy ^{Austria-Hungary.} tried to establish a "Nichtjuden Bund" in Hungary, with statutes literally translated from those of the German anti-Semitic league. The movement, however, made no progress, owing to the stalwart Liberalism of the predominant political parties, and of the national principles inherited from the Revolution. The large part played by the Jews in the struggle of 1848, and the fruitful patriotism with which they had worked for the political and economic progress of the country, had created, too, a strong claim on the gratitude of the best elements in the nation. Nevertheless, among the Ultramontane clergy, the higher aristocracy, the ill-paid minor officials, and the ignorant peasantry, the seeds of a tacit anti-Semitism were latent. It was probably the aversion of the nobility from anything in the nature of a demagogic agitation which for a time prevented these seeds from germinating. The news of the uprising in Russia and the appearance of Jewish refugees on the frontier, had the effect of giving a certain prominence to the agitation of Istoczy and Onody and of exciting the rural communities, but it did not succeed in impressing the public with the pseudo-scientific doctrines of the new anti-Semitism. It was not until the agitators resorted to the Blood Accusation—that never-failing decoy of obscurantism and superstition—that Hungary took a definite place in the anti-Semitic movement. The outbreak was short and fortunately bloodless, but while it lasted its scandals shocked the whole of Europe.

Dr August Rohling, Professor of Hebrew at the University of Prague, a Roman Catholic theologian of high position but dubious learning, had for some years assisted the Hungarian anti-Semites with *réchauffés* of Eisenmenger's *Entdecktes Judenthum* (Frankfurt a/M 1700). In 1881 he made a solemn deposition before the Supreme Court accusing the Jews of being bound by their law to work the moral and physical ruin of non-Jews. He followed this up with an offer to depose on oath that the murder of Christians for ritual purposes was a doctrine secretly taught among Jews. Professor Delitzsch and other eminent Hebraists, both Christian and Jewish, exposed and denounced the ignorance and malevolence of Rohling, but were unable to stem the mischief he was causing. In April 1882 a Christian girl named Esther Sobymossi was missed from the Hungarian village of Tisza Eszlar, where a small community of Jews were settled. The rumour got abroad that she had been kidnapped and murdered by the Jews, but it remained the burden of idle gossip, and gave rise to neither judicial complaint nor public disorders. At this moment the question of the Bosnian Pacification credits was before the Diet. The unpopularity of the task assumed by Austria-Hungary, under the Treaty of Berlin, which was calculated to strengthen the disaffected Croat element in the empire, had reduced the Government majority to very small proportions, and all the reactionary factions in the country were accordingly in arms. The Government was violently and unscrupulously attacked on all sides. On the 23rd May there was a debate in the Diet when M. Onody, in an incendiary harangue, told the story of the missing girl at Tisza Eszlar, and accused ministers of criminal indulgence to races alien to the national spirit. In the then excited state of the public mind on the Croat question, the manoeuvre was adroitly conceived. The Government fell into the trap, and treated the story with lofty disdain. Thereupon the anti-Semites set to work on the case, and M. Joseph Bary, the magistrate at Nyiregyhasa, and a noted anti-Semite, was induced to go to Tisza Eszlar and

institute an inquiry. All the anti-Liberal elements in the country now became banded together in this effort to discredit the Liberal Government, and for the first time the Hungarian anti-Semites found themselves at the head of a powerful party. Fifteen Jews were arrested and thrown into prison. No pains were spared in preparing the case for trial. Perjury and even forgery were freely resorted to. The son of one of the accused, a boy of fourteen, was taken into custody by the police, and by threats and cajoleries prevailed upon to give evidence for the prosecution. He was elaborately coached for the terrible rôle he was to play. The trial opened at Nyiregyhasa on the 19th June, and lasted till the 3rd August. It was one of the most dramatic *causes célèbres* of the century. Under the brilliant cross-examination of the advocates for the defence the whole of the shocking conspiracy was gradually exposed. The public prosecutor thereupon withdrew from the case, and the four judges—the chief of whom held strong anti-Semitic views—unanimously acquitted all the prisoners. The case proved the death-blow of Hungarian anti-Semitism. Although another phase of the Jewish question, which will be referred to presently, had still to occupy the public mind, the shame brought on the nation by the Tisza Eszlar conspiracy effectually prevented the anti-Semites from raising their voices with any effect again.

Meanwhile a more formidable and complicated outburst was preparing in Austria itself. Here the lines of the German agitation were closely followed, but with far more dramatic results. It was exclusively political—that is to say, it appealed to anti-Jewish prejudices for party purposes while it sought to rehabilitate them on a pseudo-scientific, racial, and economic basis. At first it was confined to sporadic pamphleteers. By their side there gradually grew up a school of Christian Socialists, recruited from the ultra-clericals, for the study and application of the doctrines preached at Mayence by Archbishop Ketteler. This constituted a complete Austrian analogue to the Evangelical-Socialist movement started in Germany by Herr Stoecker. For some years the two movements remained distinct, but signs of approximation were early visible. Thus one of the first complaints of the anti-Semites was that the Jews were becoming masters of the soil. This found an echo in the agrarian principles of the Christian Socialists, as expounded by Rudolph Meyer, in which individualism in landed property was admitted on the condition that the land-owners were “the families of the nation” and not “cosmopolitan financiers.” A further indication of anti-Semitism is found in a speech delivered in 1878 by Prince Alois von Liechtenstein (b. 1846), the most prominent disciple of Rudolph Meyer, who denounced the national debt as a tribute paid by the state to cosmopolitan *rentiers* (Nitti, *Catholic Socialism*, pp. 200, 201, 211, 216). The growing disorder in parliament, due to the bitter struggle between the German and Czech parties, served to bring anti-Semitism into the field of practical politics. Since 1867 the German Liberals had been in power. They had made enemies of the clericals by tampering with the concordat, and they had split up their own party by the federalist policy adopted by Count Taaffe. The Radical secessionists in their turn found it difficult to agree, and an ultra-national German wing formed itself into a separate party under the leadership of Ritter von Schönerer (b. 1842), a Radical nationalist of the most violent type. In 1882 two anti-Semitic leagues had been founded in Vienna, and to these the Radical nationalists now appealed for support. The growing importance of the party led the premier, Count Taaffe, to angle for the support of the clericals by accepting a portion of the Christian Socialist programme. The

hostility this excited in the Liberal press, largely written by Jews, served to bring the feudal Christian Socialists and Radical anti-Semites together. In 1891 these strangely assorted factions became consolidated, and during the elections of that year Prince Liechtenstein came forward as an anti-Semitic candidate and the acknowledged leader of the party. The elections resulted in the return of fifteen anti-Semites to the Reichsrath, chiefly from Vienna.

Although Prince Liechtenstein and the bulk of the Christian Socialists had joined the anti-Semites with the support of the clerical organ, the *Vaterland*, the clerical party as a whole still held aloof from the Jew-baiters. The events of 1892-95 put an end to their hesitation. The Hungarian Government, in compliance with long-standing pledges to the Liberal party, introduced into the Diet a series of ecclesiastical reform Bills providing for civil marriage, freedom of worship, and the legal recognition of Judaism on an equality with other denominations. These proposals, which synchronized with Ahlwardt's turbulent agitation in Germany, gave a great impulse to anti-Semitism and served to drive into its ranks a large number of clericals. The agitation was taken in hand by the Roman Catholic clergy, and the pulpits every Sunday resounded with denunciations of the Jews. One clergyman, Father Deckert, was prosecuted for preaching the Blood Accusation and convicted (1894). Cardinal Schlaich, bishop of Grosswardein, declared in the Hungarian House of Magnates that the Liberals were in league with “cosmopolitans” for the ruin of the country. In October 1894 the Magnates adopted two of the ecclesiastical Bills with amendments, but threw out the Jewish Bill by a majority of six. The crown sided with the Magnates, and the ministry resigned, although it had a majority in the Lower House. An effort was made to form a clerical cabinet, but it failed. Baron Banffy was then entrusted with the construction of a fresh Liberal ministry. The announcement that he would persist with the ecclesiastical Bills, lashed the clericals and anti-Semites into a fury, and the agitation broke out afresh. The pope addressed a letter to Count Zichy encouraging the Magnates to resist, and once more two of the Bills were amended, and the third rejected. The papal nuncio, Mgr. Agliardi, now thought proper to pay a visit to Budapest, where he allowed himself to be interviewed on the crisis. This interference in the domestic concerns of Hungary was deeply resented by the Liberals, and Baron Banffy requested Count Kalnoky, the imperial minister of foreign affairs, to protest against it at the Vatican. Count Kalnoky refused and tendered his resignation to the emperor. Clerical sympathies were predominant in Vienna, and the emperor was induced for a moment to decline the count's resignation. It soon became clear, however, that the Hungarians were resolved to see the crisis out, and that in the end Vienna would be compelled to give way. The emperor accordingly retraced his steps, Count Kalnoky's resignation was accepted, the papal nuncio was recalled, a batch of new Magnates were created, and the Hungarian ecclesiastical Bills passed.

Simultaneously with this crisis another startling phase of the anti-Semitic drama was being enacted in Vienna itself. Encouraged by the support of the clericals the anti-Semites resolved to make an effort to carry the Vienna municipal elections. So far the alliance of the clericals with the anti-Semites had been unofficial, but on the eve of the elections (Jan. 1895) the pope, influenced partly by the Hungarian crisis and partly by an idea of Cardinal Rampolla that the best antidote to Democratic Socialism would be a clerically controlled fusion of the Christian Socialists and anti-Semites, sent his blessing to Prince Liechtenstein and his followers. This action alarmed the Government and a considerable body of the

higher episcopate, who felt assured that any permanent encouragement given to the anti-Semites would strengthen the parties of sedition and disorder in the end. Cardinal Schoenborn was despatched in haste to Rome to expostulate with the pontiff, and his representations were strongly supported by the French and Belgian bishops. The mischief was, however, done, and although the pope sent a verbal message to Prince Liechtenstein excluding the anti-Semites from his blessing, the elections resulted in a great triumph for the Jew-haters. The municipal council was immediately dissolved by the Government, and new elections were ordered, but these only strengthened the position of the anti-Semites, who carried 92 seats out of a total of 138. A cabinet crisis followed and the premiership was entrusted to the Statthalter of Galicia, Count Badeni, who assumed office with a pledge of war to the knife against anti-Semitism. In October the new municipal council elected as burgomaster of Vienna Dr Karl Lueger (b. 1844), a vehement anti-Semite, who had displaced Prince Liechtenstein as leader of the party. The emperor declined to sanction the election, but the council repeated it in face of the imperial displeasure. Once more a dissolution was ordered and for three months the city was governed by administrative commissioners. In February 1896 elections were again held and the anti-Semites were returned with an increased majority. The emperor then capitulated; and after a temporary arrangement, by which for one year Dr Lueger acted as vice-burgomaster and handed over the burgomastership to an inoffensive nominee, permitted the municipal council to have its way. The growing anarchy in parliament at this moment served still further to strengthen the anti-Semites, and their conquest of Vienna was speedily followed by a not less striking conquest of the landtag of Lower Austria (November 1896). The zenith of their power was reached in March 1897, when, at the general election for the Reichsrath, twenty-eight anti-Semites and forty-one German clericals were elected.

Since then a reaction of sanity has gradually but surely asserted itself. For five years the anti-Semites have (1901) governed Vienna, and, although they have accomplished much mischief, the millennium of which they were supposed to be the heralds has not dawned. On the contrary, the commercial interests of the city have suffered and the rates have been enormously increased (*Neue Freie Presse*, 29th March 1901), while the predatory hopes which secured them office have only been realized on a small and select scale. The spectacle of a clerico-anti-Semitic Tammany in Vienna has strengthened the resistance of the better elements in the country. Time has also shown that Christian Socialism is only a disguise for high Toryism, and that the German radicals who were originally induced to join the anti-Semites have been victimized by the clericals. The fruits of this disillusion began to show themselves in the general elections of 1900-01, when the anti-Semites lost six seats in the Reichsrath and the clericals four, while the national German Radicals, rallied again into an independent and anti-clerical party under Ritter von Schönerer, gained thirteen seats. Three of the constituencies lost to the anti-Semites were in Vienna, and the total poll in their favour all over the city showed an enormous reduction. The elections were followed (26th January 1901) by a papal encyclical on Christian democracy, in which Christian Socialism was declared to be a term unacceptable to the Church, and the faithful were adjured to abstain from agitation of a demagogic and revolutionary character, and "to respect the rights of others."

The last country in Europe to make use of the teachings of German anti-Semitism in its party politics was France. The fact that the movement should have struck root in a republican country, where the ideals of demo-

cratic freedom have been so passionately cultivated, has been regarded as one of the paradoxes of our latter-day history. As a matter of fact, it is more surprising that it was not adopted earlier. All the social and political conditions which produced anti-Semitism in Germany were present in France, but in an aggravated form due primarily to the very republican *régime* which at first sight seemed to be a guarantee against it. In the monarchical states the dominance of the bourgeoisie was tempered in a measure by the power of the Crown and the political activity of the aristocracy, which carried with them a very real restraining influence in the matter of political honour and morality. In France these restraining influences were driven out of public life by the republic. The nobility both of the *ancien régime* and the empire stood aloof, and politics were abandoned for the most part to professional adventurers, while the bourgeoisie assumed the form of an omnipotent plutocracy. This naturally attracted to France all the financial adventurers in Europe, and in the train of the immigration came not a few German Jews, alienated from their own country by the agitation of Marr and Stoecker. Thus the bourgeoisie was not only more powerful in France than in other countries, but the obnoxiousness of its Jewish element was accentuated by a tinge of the national enemy. The anti-clericalism of the bourgeois republic and its unexampled series of financial scandals, culminating in the Panama *Krach*, thus sufficed to give anti-Semitism a strong hold on the public mind.

Nevertheless, it was not until 1882 that the anti-Jewish movement was seriously heard of in France. M. Paul Bontoux (b. 1820), who had formerly been in the employ of the Rothschilds, but had been obliged to leave the firm in consequence of his disastrous speculations, had joined the Legitimist party, and had started the Union Générale with funds obtained from his new allies. M. Bontoux promised to break up the alleged financial monopoly of the Jews and Protestants and to found a new plutocracy in its stead, which should be mainly Roman Catholic and aristocratic. The bait was eagerly swallowed. For five years the Union Générale, with the blessing of the pope, pursued an apparently prosperous career. Immense schemes were undertaken, and the 125 fr. shares rose gradually to 3200 francs. The whole structure, however, rested on a basis of audacious speculation, and in January 1882 the Union Générale failed, with liabilities amounting to 212,000,000 francs. The cry was at once raised that the *Krach* was due to the manoeuvres of the Jews, and a strong anti-Semitic feeling manifested itself in clerical and aristocratic circles. In 1886 violent expression was given to this feeling in a book since become famous, *La France Juive*, by M. Edouard Drumont (b. 1844). The author illustrated the theories of German anti-Semitism with a *chronique scandaleuse* full of piquant personalities, in which the corruption of French national life under Jewish influences was painted in alarming colours. The book was read with avidity by the public, who welcomed its explanations of the obviously growing debauchery. The Wilson scandals and the suspension of the Panama Company in the following year, while not bearing out M. Drumont's anti-Semitism, fully justified his view of the prevailing corruption. Out of this condition of things rose the Boulangist movement, which rallied all the disaffected elements in the country, including M. Drumont's following of anti-Semites. It was not, however, until the flight of General Boulanger and the ruin of his party that anti-Semitism came forward as a political movement.

The chief author of the rout of Boulangism was a Jewish politician and journalist, M. Joseph Reinach (b. 1856), formerly private secretary to M. Gambetta, and one of the ablest men in France. He was a Frenchman by birth and

education, but his father and uncles were Germans, who had founded an important banking establishment in Paris. Hence he was held to personify the alien Jewish domination in France, and the ex-Boulangists turned against him and his co-religionists with fury. The Boulangist agitation had for a second time involved the Legitimists in heavy pecuniary losses, and under the leadership of the marquis de Morès they now threw all their influence on the side of M. Drumont. An anti-Semitic league was established, and with Royalist assistance branches were organized all over the country. The Franco-Russian alliance in 1891, when the persecutions of the Jews by M. Pobedonostzeff were attracting the attention of Europe, served to invest M. Drumont's agitation with a fashionable and patriotic character. It was a sign of the spiritual approximation of the two peoples. In 1892 M. Drumont founded a daily anti-Semitic newspaper, *La Libre Parole*. With the organization of this journal a regular campaign for the discovery of scandals was instituted. At the same time a body of aristocratic swashbucklers, with the marquis de Morès and the count de Lamase at their head, set themselves to terrorize the Jews and provoke them to duels. At a meeting held at Neuilly in 1891 M. Guérin, one of the marquis de Morès's lieutenants, had demanded rhetorically *un cadavre de Juif*. He had not long to wait. Anti-Semitism was most powerful in the army, which was the only branch of the public service in which the reactionary classes were fully represented. The republican law compelling the seminarists to serve their term in the army had strengthened its clerical and Royalist elements, and the result was a movement against the Jewish officers, of whom 500 held commissions. A series of articles in the *Libre Parole* attacking these officers led to a number of ferocious duels, and these culminated in 1892 in the death of an amiable and popular Jewish officer, Captain Armand Mayer, of the Engineers, who fell, pierced through the lungs by the marquis de Morès. This tragedy, rendered all the more painful by the discovery that Captain Mayer had chivalrously fought to shield a friend, aroused a great deal of popular indignation against the anti-Semites, and for a moment it was believed that the agitation had been killed with its victim.

Towards the end of 1892, the discovery of the widespread corruption practised by the Panama Company gave a fresh impulse to anti-Semitism. The revelations were in a large measure due to the industry of the *Libre Parole*; and they were all the more welcome to the readers of that journal since it was discovered that three Jews were implicated in the scandals, one of whom, baron de Reinach, was uncle and father-in-law to the hated destroyer of Boulangism. The escape of the other two, Dr Herz and M. Arton, and the difficulties experienced in obtaining their extradition, deepened the popular conviction that the authorities were implicated in the scandals, and kept the public eye for a long time absorbed by the otherwise restricted Jewish aspects of the scandals. In 1894 the military side of the agitation was revived by the arrest of a prominent Jewish staff officer, Captain Alfred Dreyfus, on a charge of treason. From the beginning the hand of the anti-Semite was flagrant in the new sensation. The first hint of the arrest appeared in the *Libre Parole*; and before the facts had been officially communicated to the public that journal was busy with a campaign against the war minister, based on the apprehension that, in conspiracy with the *Juiverie* and his republican colleagues, he might exert himself to shield the traitor. Anti-Semitic feeling was now thoroughly aroused. Panama had prepared the people to believe anything; and when it was announced that a court-martial, sitting in secret, had convicted Dreyfus, there was a howl of execration against the Jews from one end of

the country to the other, although the alleged crime of the convict and the evidence by which it was supported were quite unknown. Dreyfus was degraded and transported for life amid unparalleled scenes of public excitement.

The Dreyfus Case registers the climax not only of French, but of European anti-Semitism. It was the most ambitious and most unscrupulous attempt yet made to prove the nationalist hypothesis of the anti-Semites, and in its failure it afforded the most striking illustration of the dangers of the whole movement by bringing France to the verge of revolution. For a few months after the Dreyfus court-martial there was a comparative lull; but the highly-strung condition of popular passion was illustrated by a violent debate on "The Jewish Peril" in the Chamber of Deputies (25th April 1895), and by two outrages with explosives at the Rothschild Bank in Paris. Meanwhile the family of Dreyfus, absolutely convinced of his innocence, were casting about for the means of clearing his character and securing his liberation. They were wealthy, and their activity unsettled the public mind and aroused the apprehensions of the conspirators. Had the latter known how to preserve silence, the mystery would perhaps have been yet unsolved; but in their anxiety to allay all suspicions they made one false step, which proved the beginning of their ruin. Through their friends in the press they secured the publication of a facsimile of a document known as the *Bordereau*—a letter supposed to be in Dreyfus's handwriting and addressed apparently to the military attaché of a foreign power, which was alleged to constitute the chief evidence against the convict. It was hoped by this publication to put an end to the doubts of the so-called Dreyfusards. The result, however, was only to give them a clue on which they worked with remarkable ingenuity. To prove that the *Bordereau* was not in Dreyfus's handwriting was not difficult. Indeed, its authorship was recognized almost on the day of publication; but the Dreyfusards held their hands in order to make assurance doubly sure by further evidence. Meanwhile one of the officers of the general staff, Colonel Picquart, had convinced himself by an examination of the *dossier* of the trial that a gross miscarriage of justice had taken place. On mentioning his doubts to his superiors, who were animated partly by anti-Semitic feeling and partly by reluctance to confess to a mistake, he was ordered to the Tunisian hinterland on a dangerous expedition. Before leaving Paris, however, he took the precaution to confide his discovery to his legal adviser. Harassed by their anxieties, the conspirators made further communications to the newspapers; and the Government, questioned and badgered in parliament, added to the revelations. The new disclosures, so far from stopping the Dreyfusards, proved to them, among other things, that the conviction had been partially based on documents which had not been communicated to the counsel for the defence, and hence that the judges had been tampered with by the Ministry of War behind the prisoner's back. So far, too, as these documents related to correspondence with foreign military attachés, it was soon ascertained that they were forgeries. In this way a terrible indictment was gradually drawn up against the Ministry of War. The first step was taken towards the end of 1897 by a brother of Captain Dreyfus, who, in a letter to the minister of war, denounced Major Esterhazy as the real author of the *Bordereau*. The authorities, supported by parliament, declined to re-open the Dreyfus Case, but they ordered a court-martial on Esterhazy, which was held with closed doors and resulted in his acquittal. It now became clear that nothing short of an appeal to public opinion and a full exposure of all the iniquities that had been perpetrated would secure justice

at the hands of the military chiefs. On behalf of Dreyfus, M. Zola, the eminent novelist, formulated the case against the general staff of the army in an open letter to the president of the republic, which by its dramatic accusations startled the whole world. The letter was denounced as wild and fantastic even by those who were in favour of revision. M. Zola was prosecuted for libel and convicted, and had to fly the country; but the agitation he had started was taken in hand by others, notably M. Clemenceau, M. Reinach, and M. Yves Guyot. In August 1898 their efforts found their first reward. A re-examination of the documents in the case by M. Cavaignac, then minister of war, showed that one was undoubtedly forged. Colonel Henry, of the Intelligence Department of the War Office, then confessed that he had fabricated the document, and, on being sent to Mont Valérien under arrest, cut his throat.

In spite of this damaging discovery the War Office still persisted in believing Dreyfus guilty, and opposed a fresh inquiry. It was supported by three successive ministers of war, and apparently an overwhelming body of public opinion. By this time the question of the guilt or innocence of Dreyfus had become an altogether subsidiary issue. As in Germany and Austria, the anti-Semitic crusade had passed into the hands of the political parties. On the one hand the Radicals and Socialists, recognizing the anti-republican aims of the agitators and alarmed by the clerical predominance in the army, had thrown in their lot with the Dreyfusards; on the other the reactionaries, anxious to secure the support of the army, took the opposite view, denounced their opponents as *sans patrie*, and declared that they were conspiring to weaken and degrade the army in the face of the national enemy. The controversy was, consequently, no longer for or against Dreyfus, but for or against the army, and behind it was a life-or-death struggle between the republic and its enemies. The situation became alarming. Rumours of military plots filled the air. Powerful leagues for working up public feeling were formed and organized; attempts to discredit the republic and intimidate the Government were made. The president was insulted; there were tumults in the streets, and an attempt was made by M. Déroulède to induce the military to march on the Elysée and upset the republic. In this critical situation France, to her eternal honour, found men with sufficient courage to do the right. The Socialists, by rallying to the Radicals against the reactionaries, secured a majority for the defence of the republic in parliament. M. Brisson's Cabinet transmitted to the Court of Cassation an application for the revision of the case against Dreyfus; and that tribunal, after an elaborate inquiry, which fully justified M. Zola's famous letter, quashed and annulled the proceedings of the court-martial, and remitted the accused to another court-martial, to be held at Rennes. Throughout these proceedings the military party fought tooth and nail to impede the course of justice; and although the innocence of Dreyfus had been completely established, it concentrated all its efforts to secure a fresh condemnation of the prisoner at Rennes. Popular passion was at fever heat, and it manifested itself in an attack on M. Labori, one of the counsel for the defence, who was shot and wounded on the eve of his cross-examination of the witnesses for the prosecution. To the amazement and indignation of the whole world outside France, the Rennes court-martial again found the prisoner guilty; but all reliance on the conscientiousness of the verdict was removed by a rider, which found "extenuating circumstances," and by a reduction of the punishment to ten years' imprisonment, to which was added a recommendation to mercy. The verdict was evidently an attempt at a compromise, and the Government resolved to advise the president of the republic to pardon

Dreyfus. This lame conclusion did not satisfy the accused; but his innocence had been so clearly proved, and on political grounds there were such urgent reasons for desiring a termination of the affair, that it was accepted without protest by the majority of moderate men. The explanation of the whole case is that Esterhazy and Henry were the real culprits; that they had made a trade of supplying the German Government with military documents; and that, when the *Bordereau* was discovered, they availed themselves of the anti-Semitic agitation to throw suspicion on Dreyfus.

The rehabilitation of Dreyfus did not pass without another effort on the part of the reactionaries to turn the popular passions excited by the case to their own advantage. After the failure of M. Déroulède's attempt to overturn the republic, the various Royalist and Boulangist leagues, with the assistance of the anti-Semites, organized another plot. This was discovered by the Government, and the leaders were arrested. M. Jules Guérin, secretary of the anti-Semitic league, shut himself up in the league offices in the Rue Chabrol, Paris, which had been fortified and garrisoned by a number of his friends, armed with rifles. For more than a month the anti-Semites held the authorities at bay, and some 5000 troops were employed in the siege. The conspirators were all tried by the Senate, sitting as a high court, and M. Guérin was sentenced to ten years' imprisonment. The evidence showed that the anti-Semitic organization had taken an active part in the anti-republican plot (see the report of the Commission d'Instruction in the *Petit Temps*, 1st November 1899). This vigorous action of the Government, together with the moral effect of the Dreyfus Case, has seriously weakened the anti-Semitic movement in France, and it has now completely lost its hold on the public outside Paris.

In sympathy with the agitation in France there has been a similar movement in Algeria, where the European population have long resented the admission of the native Jews to the rights of French citizenship. The agitation has been marked by much violence, and most of the anti-Semitic deputies in the French parliament, including M. Drumont, have found constituencies in Algeria. As the local anti-Semites are largely Spaniards and Levantine riff-raff, the agitation has not the peculiar nationalist bias which characterizes Continental anti-Semitism. Before the energy of the authorities it has lately shown signs of subsiding.

While the main activity of anti-Semitism has manifested itself in Germany, Russia, Rumania, Austria-Hungary, and France, its vibratory influences have been felt in other countries when conditions favourable to its extension have presented themselves. In England more than one attempt to acclimatize the doctrines of Marr and Treitschke has been made. The circumstance that at the time of the rise of German anti-Semitism a premier of Hebrew race, Lord Beaconsfield, was in power first suggested the Jewish bogey to English political extremists. The Eastern Crisis of 1876-78, which was regarded by the Liberal party as primarily a struggle between Christianity, as represented by Russia, and a degrading Semitism, as represented by Turkey, accentuated the anti-Jewish feeling, owing to the anti-Russian attitude adopted by the Government. Violent expression to the ancient prejudices against the Jews was given by Sir J. G. Tollemache Sinclair (*A Defence of Russia*, 1877). Mr T. P. O'Connor, in a life of Lord Beaconsfield (1878), pictured him as the instrument of the Jewish people, "moulding the whole policy of Christendom to Jewish aims." Professor Goldwin Smith, in several articles in the *Nineteenth Century* (1878, 1881, and 1882), sought to synthesize the growing anti-Jewish feeling by adopting the nationalist theories of the German anti-Semites. This movement did not fail to find an

Great Britain, etc.

equivocal response in the speeches of some of the leading Liberal statesmen; but on the country generally it produced no effect. It was revived when the persecutions in Russia threatened England with a great influx of Polish Jews, whose mode of life was calculated to lower the standard of living in the industries in which they were employed. All danger was, however, averted by the Jewish communal authorities, who, by dint of great pecuniary sacrifices and an excellent international organization, managed to control the immigration. In 1883 Herr Stoecker visited London, but received a very unflattering reception. Equally abortive attempts to acclimatize anti-Semitism have been made in Switzerland, Belgium, Greece, and the United States.

Anti-Semitism has made a great deal of history during the last thirty years, but it has left no permanent mark on the social and political evolution of Europe. It is the fruit of a great ethnographic and political error, and it has spent itself in political intrigues of transparent dishonesty. Its racial doctrine is at best a crude hypothesis; its nationalist theory has only served to throw into striking relief the essentially economic bases of modern society, while its political activity has revealed the vulgarity and ignorance which constitute its main sources of strength. So far from injuring the Jews, it has really given Jewish racial separatism a new lease of life. Its extravagant accusations, as in the Tisza Eszlar and Dreyfus cases, have resulted in the vindication of the Jewish character. Its agitation generally, coinciding with the revival of interest in Jewish history, has helped to transfer Jewish solidarity from a religious to a racial basis. The bond of a common race, vitalized by a new pride in Hebrew history and spurred on to resistance by the insults of the anti-Semites, has given a new spirit and a new source of strength to Judaism at a moment when the approximation of ethical systems and the revolt against dogma were sapping its essentially religious foundations. In the whole history of Judaism, perhaps, there have been no more numerous or remarkable instances of reversions to the faith than during the last thirty years. The reply of the Jews to anti-Semitism has taken two interesting practical forms. In the first place there is the so-called Zionist movement, which is a kind of Jewish nationalism and is vitiated by the same errors that distinguish its anti-Semitic analogue. It aims at the re-establishment of the Jewish state; and, under the leadership of Dr Theodor Herzl (b. 1860) and Dr Max Nordau (b. 1849) it has found no fewer than a quarter of a million supporters, who are now definitely organized. In the second place, there is a movement represented by the Maccabæans' Society in London, which seeks to unite the Jewish people in an effort to raise the Jewish character and to promote a higher consciousness of the dignity of the race. It lays no stress on orthodoxy, but welcomes all who strive to render Jewish conduct an adequate reply to the theories of the anti-Semites. Both these movements are elements of fresh vitality to Judaism, and they are probably destined to produce important fruit in the near future. A splendid spirit of generosity has also been displayed by the Jewish community in assisting and relieving the victims of the Jew-haters. Besides countless funds raised by public subscription, Baron de Hirsch founded a colossal scheme for transplanting persecuted Jews to new countries under new conditions of life, and endowed it with no less a sum than £9,000,000 (see HIRSCH, MORITZ DE).

Though anti-Semitism has been unmasked and discredited, it is to be feared that its history is not yet at an end. While there are in Russia and Rumania six millions of Jews who are being systematically degraded, and who periodically overflow the western frontier, there will continue to be a Jewish question in Europe; and while there are weak Governments, as in Austria and France, and

ignorant and superstitious elements in the enfranchised classes of those countries, that question will seek to play a part in politics.

LITERATURE.—No impartial history of modern anti-Semitism has yet been written. The most comprehensive works on the subject, *Israel among the Nations*, by A. LÉROY-BEAULIEU (1895), and *L'Antisémisme, son Histoire et ses causes*, by BERNARD LAZARE (1894), are collections of studies rather than histories. M. Lazare's work will be found most useful by the student on account of its detached standpoint and its valuable bibliographical notes. A good list of works relating to Jewish ethnography will be found at the end of M. Isidore Loeb's valuable article, "Juifs," in the *Dictionnaire Universel de Géographie* (1884). To these should be added JELLINEK, *Der Jüdische Stamm* (1869); CHWOLSON, *Die Semitischen Völker* (1872); NOSSIG, *Materialien zur Statistik* (1887); JACOBS, *Jewish Statistics* (1891); and ANDRÉE, *Zur Volkskunde der Juden* (1881). A bibliography of the Jewish question from 1875 to 1884 has been published by Mr Joseph Jacobs (1885). Useful additions and rectifications will be found in the *Jewish World*, 11th September 1885. During the last fifteen years the anti-Semitic movement has produced an immense pamphlet literature. Some of these productions have already been referred to; others will be found in current bibliographies under the names of the personages mentioned, such as Stoecker, Ahlwardt, &c. On the Russian persecutions, besides the works quoted by Jacobs, see the pamphlet issued by the Russo-Jewish Committee in 1890, and the annual reports of the Russo-Jewish Mansion House Fund; *Les Juifs de Russie* (Paris, 1891); *Report of the Commissioners of Immigration upon the Causes which incite Immigration to the United States* (Washington, 1892); *The New Exodus*, by HAROLD FREDERIC (1892); *Les Juifs Russes*, by LEO ERRERA (Brussels, 1893). The most valuable collection of facts relating to the persecutions of 1881-82 are to be found in the *Feuilles Jaunes* (52 nos.), compiled and circulated for the information of the European press by the Alliance Israélite de Paris. Complete collections are very scarce. On the Rumanian question, see BLUNTSCHLI, *Roumania and the Legal Status of the Jews* (London, 1879); *Wir Juden* (Zurich, 1883); SCHLOSS, *The Persecution of the Jews in Roumania* (London, 1885); SCHLOSS, *Notes of Information* (1886); SINCERUS, *Juden en Roumanie* (London, 1901); PLOTKE, *Die Rumänischen Juden unter dem Fürsten u. König Karl* (1901); DEHN, *Diplomatie u. Hochfinanz in der Rumänischen Judenfrage* (1901); CONYBEARE, *Roumania as a Persecuting Power* (*Nat. Rev.* February 1901). On Hungary and the Tisza Eszlar Case, see, besides the references in Jacobs, NATHAN, *Der Prozess von Tisza Eszlar* (Berlin, 1892). On this case and the Blood Accusation generally, see WRIGHT, "The Jews and the Malignant Charge of Human Sacrifice" (*Nineteenth Century*, 1883). The origins of the Austrian agitation are dealt with by NITTI, *Catholic Socialism* (1895). This work, though inclining to anti-Semitism, should be consulted for the Christian Socialist elements in the whole Continental agitation. The most valuable source of information on the Austrian movement is the *Oesterreichische Wochenschrift*, edited by Dr BLOCH. See also pamphlets and speeches by the anti-Semitic leaders, LICHTENSTEIN, LUEGER, SCHÖRNERER, &c. The case of the French anti-Semites is stated by E. DRUMONT in his *France Juive*, and other works; the other side by Isidor Loeb, Bernard Lazare, Leonce Reynaud, &c. Of the Dreyfus Case there is an enormous literature; see especially the reports of the Zola and Picquart trials, the revision case before the Court of Cassation, and the proceedings of the Rennes court-martial; also the valuable series of volumes by Captain Paul Marin, MM. Clemenceau, Reinach, Lazare, Yves Guyot, Paschal Grousset, Urbain Gohier, De Haime, De Pressensé, and the remarkable letters of DREYFUS (*Lettres d'un innocent*). An English history of the case has been published by Mr Conybeare, whose articles and those of Sir Godfrey Lushington and Mr Maxse in the *National Review*, 1897-1900, will be found invaluable by the student. On the Algerian question, see M. WAHL in the *Revue des Études Juives*; L. FOREST, *Naturalisation des Israélites Algériens*; and E. AUDINER in the *Revue Générale de Droit International Publique*, 1897, No. 4. A good summary of the aims and literature of Zionism will be found in the *Nineteenth Century*, August 1897. On the history of the anti-Semitic movement generally, see the annual reports of the Alliance Israélite de Paris and the Anglo-Jewish Association of London, also the annual summaries published at the end of the Jewish year by the *Jewish Chronicle* of London. The connexion of the movement with general party politics must be followed in the newspapers. The present writer has worked with a collection of newspaper cuttings numbering several thousands and ranging over twenty years. A skeleton guide may be obtained by a careful study of SEIGENBOS, *Histoire Politique de l'Europe Contemporaine* (1897), aided by *Hazell's Annual*, and SCHULTHESS, *Europäischer Geschichtskalender*. (L. W.)

Antitoxin. See BACTERIOLOGY, II.

Antivari, or BAR, so called from its position opposite Bari in Italy, once a town of Turkish Albania, now Montenegrin, situated near the Adriatic Sea, 18 miles N.W. of Scutari, and surrounded by a dense forest of olive trees. Its old Venetian castle suffered greatly from the siege by the Montenegrins in 1878, and is now in ruins. There is a good harbour (Pristan) for vessels of light draught, and a beautiful residence for the prince one hour distant from the town, which had at one time a considerable trade in the products of Albania, but is now of little importance. It is the seat of a Roman Catholic archbishop. Population, about 1500, mostly Albanians.

Antofagasta, a town and port on the Pacific and the capital of the Chilean province and department of the same name, situated in 23° 38' 39" S. lat. and 70° 24' 39" W. long., about 768 miles N. of Valparaiso. It belonged to Bolivia until occupied in 1879 by Chile, then at war with the former country; its occupation was agreed to by Peru in 1884, and it was definitely ceded to Chile by the treaty of 1885. The population in 1895 was 13,530; in 1898 it was estimated at 16,795. It is the head of the railway to Oruro in Bolivia, and most of the Bolivian export trade passes through it. The total value of the exports in 1897 was (Chilian currency) \$4,237,841; of the imports, \$2,187,171. In the same year the shipping which entered had a tonnage of 75,224 tons. The value of the Bolivian mineral products exported through it in 1898 was \$29,994,914 (Chilian currency). The province of ANTOFAGASTA has an area of 47,918 square miles, and had in 1895 a population of 44,085. It is divided into three departments. In 1898 the marriages numbered 253, the births 1561, and the deaths 1093.

Antonelli, Giacomo (1806-1876), Italian Cardinal, was born at Sonnino, 2nd April 1806. He was educated for the priesthood, but, after taking orders, preferred an administrative career. Created secular prelate, he was sent as apostolic delegate to Viterbo, where he early manifested his reactionary tendencies in an attempt to stamp out Liberalism. Recalled to Rome in 1841, he entered the office of the papal secretary of state, but four years later was appointed pontifical treasurer-general. Created cardinal (11th June 1847), he was chosen by Pius IX. to preside over the council of state entrusted with the drafting of the constitution. On 10th March 1848 Antonelli became premier of the first constitutional ministry of Pius IX., a capacity in which he displayed unscrupulous duplicity. Upon the fall of his cabinet Antonelli created for himself the governorship of the sacred palaces in order to retain constant access to and influence over the Pope. After the assassination of Pellegrino Rossi (15th November 1848) he arranged the flight of Pius IX. to Gaeta, where he was appointed secretary of state. Notwithstanding promises to the Powers, he restored absolute government upon returning to Rome (12th April 1850) and violated the conditions of the surrender by wholesale imprisonment of Liberals. In 1855 he narrowly escaped assassination. As ally of the Bourbons of Naples, from whom he had received an annual subsidy, he attempted, after 1860, to facilitate their restoration by fomenting brigandage on the Neapolitan frontier. To the overtures of Ricasoli in 1861, Pius IX., at Antonelli's suggestion, replied with the famous "*Non possumus*," but subsequently (1867) accepted, too late, Ricasoli's proposal concerning ecclesiastical property. After the September Convention (1864) Antonelli organized the Legion of Antibes to replace French troops in Rome, and in 1867 secured French aid against Garibaldi's invasion of papal territory. Upon the reoccupation of Rome by the French after Mentana, Antonelli

again ruled supreme, but upon the entry of the Italians in 1870 was obliged to restrict his activity to the management of foreign relations. He wrote, with papal approval, the letter requesting the Italians to occupy the Leonine city, and obtained from the Italians payment of the Peter's pence (5,000,000 lire) remaining in the papal exchequer, as well as 50,000 scudi—the first and only instalment of the Italian allowance ever accepted by the Holy See. At Antonelli's death in 1876 the Vatican finances were found to be in disorder, with a deficit of 45,000,000 lire. His personal fortune, accumulated during office, was considerable, and was bequeathed entirely to members of his family. From 1850 until his death he interfered little in affairs of dogma and church discipline, although he addressed to the Powers circulars enclosing the Syllabus (1864) and the acts of the Vatican Council (1870). His activity was devoted almost exclusively to the political aspects of the struggle between the papacy and the Italian Risorgimento. (H. W. S.)

Antrim, a maritime county of Ireland, province of Ulster, bounded on the N. and N.E. and E. by the North Channel, on the S. by Co. Down, on the S.W. by Lough Neagh, and on the W. by Co. Londonderry.

Population.—The area of the administrative county in 1899 was 711,487 acres, of which 225,926 were tillage, 358,080 pasture, 747 fallow, 6140 plantation, 24,170 turf bog, 6538 marsh, 51,896 barren mountain, and 37,990 water, roads, fences, &c. The new administrative county under the Local Government (Ireland) Act, 1898, includes the portion of the town of Lisburn formerly situated in Down, and the town of Carrickfergus, formerly a separate county, but does not include the portion of the city of Belfast formerly situated in Antrim. The population in 1881 was 421,943, and in 1891, 428,128, of whom 200,514 were males and 227,614 females, divided as follows among the different religions: Presbyterians, 180,375; Roman Catholics, 106,390; Protestant Episcopalians, 106,244; Methodists, 14,745; other denominations, 20,162. The increase of population between 1881 and 1891 was 1.47 per cent., the largest percentage of increase in Ireland. The average number of persons to an acre was .56. Of the total population 176,923 inhabited the rural districts, being an average of 205 persons to each square mile under crops and pasture. In 1901 the population was 461,240, showing an increase of 7 per cent.

Education.—The following table gives the degree of education in 1891 (excluding Belfast and Carrickfergus):—

	Males.	Females.	Total.	Percentage.		
				R.C.	Pr. Epis.	Presb.
Read and write . . .	68,497	70,920	139,417	64.6	71.8	80.5
Read only . . .	10,786	16,806	27,592	17.3	16.8	18.8
Illiterate . . .	8,202	9,322	17,524	18.1	11.4	5.7

In 1881 the percentage of illiterates among Roman Catholics was 24.0. In 1891 in the whole county there were 53 superior schools with 3470 pupils (613 Roman Catholics and 2857 Protestants), and 735 primary schools with 67,446 pupils (15,419 Roman Catholics and 52,027 Protestants). The number of pupils on the rolls of the national schools on 30th September 1899 was 80,943, of whom 18,200 were Roman Catholics and 62,743 Protestants.

The following table gives the number of births, deaths, and marriages in various years:—

Year.	Births.	Deaths.	Marriages.
1881	12,869	8484	2631
1891	12,459	9586	3255
1899	13,374	9982	3582

In 1899 the birth-rate per 1000 was 31.0, and the death-rate 23.2; the rate of illegitimacy was 4.3 per cent. of the total births. The total number of emigrants who left the county between 1st May 1851 and 31st December 1899 was 249,354, of whom 144,588 were males and 104,766 females. The chief towns in the county are Belfast, 348,965; Lisburn, 11,459; Carrickfergus, and Ballymena.

Administration.—The county is divided into four parliamentary divisions—north, mid, east, and south; the number of registered electors in 1900 being respectively 8600, 8219, 8886, and 10,361. The rateable valuation in 1900 was £693,685, the county borough

of Belfast being now rated separately. By the Local Government (Ireland) Act, 1898, the fiscal and administrative duties of the grand jury (and to a less extent) of other bodies were transferred to a county council, urban and rural district councils were established, and under that Act the county now comprises six urban and eight rural sanitary districts. The same Act abolished the separate county of the town of Carrickfergus and constituted the city of Belfast a separate county.

Agriculture.—The following tables show the acreage under crops, including meadow and clover, and the amount of live stock in 1881, 1891, 1895, and 1899. The figures for 1899 are for the new administrative county:—

	Wheat.	Oats.	Barley, Beans, etc.	Potatoes.	Turnips.	Other green Crops.	Flax.	Meadow and Clover.	Total.
1881	4442	76,445	8892	46,027	9,471	8044	17,662	87,947	248,950
1891	1967	67,540	2850	41,598	10,402	1962	15,010	90,168	231,022
1895	741	67,858	1599	40,251	11,419	1518	15,873	98,022	236,281
1899	1859	66,020	1711	37,498	12,148	2223	8,012	96,955	225,926

In 1899 the total value of the cereal and other crops was estimated by the Registrar-General at £1,768,536. The number of acres under pasture in 1881 was 340,120; in 1891, 345,554; and in 1899, 358,080.

	Horses and Mules.	Asses.	Cattle.	Sheep.	Pigs.	Goats.	Poultry.
1881	29,748	576	188,519	56,849	46,821	5074	450,180
1891	32,147	676	157,550	122,428	65,885	6859	573,384
1895	34,876	687	158,662	98,226	61,205	5892	600,865
1899	33,512	752	156,388	100,845	60,860	5825	714,595

The number of milch cows in 1891 was 64,365, and in 1899, 64,875. It is estimated that the total value of cattle, sheep, and pigs in 1899 was £2,305,016.

In 1899 the number of holdings not exceeding 1 acre was 2678; between 1 and 5, 2000; between 5 and 15, 5346; between 15 and 30, 5992; between 30 and 50, 3646; between 50 and 100, 2374; between 100 and 200, 556; between 200 and 500, 155; and above 500, 46—total, 22,793. The total number of loans issued (the number of tenants being the same as the number of loans) under the Land Purchase Acts, 1885, 1891, 1896, up to 31st March 1900, was 3521, amounting to £1,134,873. The number of loans sanctioned for agricultural improvements under sect. 31 of the Land Act, 1881, between 1882 and 1900 was 182, and the amount issued was £11,415. The total amount issued for all classes of works under the Land Improvement Acts from the commencement of operations in 1847 to 31st March 1900 was £138,203.

Minerals.—The following were the outputs of the various mines in 1899,—coal, 6111 tons, iron ore, 102,262 tons, value £16,016; rock salt, 47,055 tons, value £13,319; and alum clay, 8099 tons, value £1871. The output of iron ore has been almost continually increasing, and the production of alumina from alum clay forms a new branch of industry. The alumina is prepared at works near Larne; 1500 tons, value £28,000, having been extracted in 1899.

Fisheries.—In 1899, 231 vessels, employing 476 hands, were registered in the deep sea and coast fishing districts of Ballycastle and Carrickfergus. 212 persons were employed in the salmon fishing district of Ballycastle in the same year.

Antrim, a town in the above county, on the Six-mile Water, 13 miles N.W. of Belfast by rail, on the Great Northern railway. It is governed by town commissioners, but, under the Local Government (Ireland) Act, 1898, can apply to be constituted an urban sanitary district. Area, 198 acres. Population (1891), 1385; (1901), 1825.

Antwerp (French *Anvers*), a city, port, and stronghold of Belgium, capital of the province of the same name, on the right bank of the Scheldt, about 50 miles from the sea and 25 N. of Brussels by rail. The wall which, since the old fortifications were demolished in 1860, has shut in the city wherever unprotected by the river, encloses the suburbs of Borgerhout and Berchem, and measures over 8½ miles; seventeen gates give entrance to the city, and twelve forts serve for the defence. The city has spread rapidly within recent years; a new quarter has sprung up all along the line of the old fortifications, containing many handsome erections such as the new Art Gallery, the Law Courts, the National Bank, the National Theatre, and the

Athenæum. But it is the commercial importance of Antwerp which above all else distinguishes the city. In this direction the dock accommodation is still insufficient for the vast and still growing trade, though considerable extensions have been carried out, and the quays now stretch along the Scheldt for 2½ miles. These are backed by large warehouses, on the top of which a fine promenade has been constructed, and behind these again open out thirteen basins of various sizes. Sixty shipping lines have their headquarters at Antwerp, and in conjunction with numerous other lines which make it a port of call place the city in communication with every part of the world. In 1880, 4495 vessels (2292 British) of 3,063,825 tons entered the port; in 1899, 5613 (3013 British) of 6,872,848 tons. Imports were valued at £49,700,000 in 1880, and £65,027,600 in 1899; exports at £16,533,000

in 1880, and £32,615,000 in 1899. The principal imports are now, in order of importance, grain of all kinds, raw textile materials (wool, cotton, flax, &c.), mineral ores and metals, provisions, rice, animal products, and guano; the principal exports are glass-ware, wrought metal, railway carriages, cement, worsted and thread. Antwerp proper has nearly doubled its population within the last twenty-five years. In 1875 there were 148,800 inhabitants; in 1880, 169,100; in 1890, 224,000; and in 1899, 282,000. Including the two suburbs of Borgerhout and Berchem, the total population in 1899 was 338,800.

The province of ANTWERP (Fr. *Anvers*), Belgium, between the Netherlands on the N. and E., the province of Limbourg on the E., Brabant on the S., and East Flanders on the W., is formed of the ancient territories of the marquisate of Antwerp and the lordship of Malines and of a part of the ancient duchy of Brabant. The land spreads out flat and low. In large part Antwerp belongs to the sandy region known as the Campine. A canal from Antwerp to Maastricht joins the basin of the Scheldt to that of the Meuse. Besides its important commercial centre of Antwerp, the province carries on the industries of shipbuilding, paper-making, woollen textiles, and cement. It is divided into the three administrative arrondissements of Antwerp, Malines, and Turnhout. The province covers 1093 square miles, with a population in 1899 of 825,000 (or 753·7 to a square mile) against 531,750 in 1875. The arrondissement of Antwerp had a population in 1899 of 513,500, or 1367·5 per square mile.

See MERTENS ET TORFS. *Geschiedenis van Antwerpen*.—EUG. GENS. *Histoire de la ville d'Anvers*.—GÉNARD. *Anvers à travers les âges*.—*Rapport de la Chambre de Commerce d'Anvers*, 1898; and *Annuaire statistique de la Belgique*, 1899. (J. DU F.)

Anuradhapura, the chief town in the north-central province of Ceylon, and the ancient capital of the island for twelve centuries from 437 B.C. It is an extensive "buried city," now being gradually excavated under an archaeological survey by the government of Ceylon. Its dagabas and other Buddhist ruins excite much interest. It can be visited by rail and coach in two days from Colombo; but the railway is about to be extended all the way. Population—town, 3000; province, 79,022.

Anzin, a town of France, department of Nord, in the arrondissement of Valenciennes, 1½ miles N.W. of that town, of which it is a suburb, on the railway from Somain to Péruwelz. Its metallurgical industries are very extensive, and include several large establishments engaged in the manufacture of steam engines, machinery, chain-cables, and a great variety of heavy iron goods. The number of puddling furnaces in operation in Anzin and Denain in 1899 was 25. The output of coal in the same year

from the mines under the control of the Société d'Anzin was 2,973,000 tons, and the number of persons employed was 12,200. Population (1891), 11,394; (1896), 12,606; (comm.), 12,768.

Apamea, (1) a treasure-city, and stud-depot of the Seleucid kings in the valley of the Orontes. Destroyed by Chosroes in the 7th century A.D.; partially rebuilt and known as *Fámia* by the Arabs; and overthrown by an earthquake in 1152. The acropolis hill is now occupied by the ruins of Kalat el-Mudfk. (2) In Phrygia. Founded by Antiochus Soter, near, but on lower ground than, Celænæ. It was situated at the exit of the Marsyas from the hills, and became a seat of Seleucid power, and a centre of Greco-Roman civilization and commerce. For a long period it was one of the greatest cities of Asia Minor, but when the trade routes were diverted to Constantinople it rapidly declined, and its ruin was completed by an earthquake. An early Christian tradition, possibly arising from a name, *Cibotos* (ark), which the town bore, identified the neighbouring mountain with Ararat. The site is now partly occupied by Dineir, which is connected with Smyrna by railway, and there are extensive remains. (3) On the left bank of the Euphrates, at the end of a bridge of boats (*zeugma*). The Til-Barsip of the Assyrian inscriptions, now Birejik. (4) The earlier Myrlea of Bithynia, now Mudánia, the port of Brúsa.

HIRSCHFELD, "Über Celainai-Apameia-Kibotos," in *Transactions of Berlin Academy*, 1876.—HOGARTH, in *Journal of Hellenic Studies*, 1888.—RAMSAY, *Cities and Bishoprics of Phrygia*, vol. ii. Oxford.

Apeldoorn, a flourishing village in the Netherlands, in the province of Gelderland, 17 miles north of Arnhem. The Protestant church, burned down in 1890, has been restored, and an aqueduct built (1894) from the neighbouring hills. Population (1900), 25,761.

Apennines, the mountain backbone of Italy, some 800 miles long by 70 to 80 miles in maximum width. The central chain, or main axis, of the Apennines may perhaps be regarded as a flanking range of a primeval central mass now sunk beneath the Tyrrhenian Sea, and the Apuan Alps, a western outlier of the Northern Apennines, and the mountains of Calabria, which are the oldest parts of the system, being composed almost entirely of crystalline rocks, as surviving fragments of the same primeval Tyrrhenian mainland. Apart from the Apuan Alps, the Northern Apennines consist principally of older Tertiary formations and younger members of the Cretaceous epoch, chiefly sandstones and marly slates, broken through in many places by rounded protrusions of gabbro and serpentine. These serpentine outflows occur again in the "compartment" of Potenza (province, Basilicata) in the south, but do not appear in the Central Apennines. The Central Apennines may be briefly described as consisting of a series of vast ellipsoidal outcrops of the limestone core (Cretaceous to Triassic) of the system, thrust up above the broad base of younger formations, which flank it on east and west. South of the Esino valley and the Ancona-Spoleto railway there are two clearly marked continuing ranges, with parallel strikes, the western prolonging the Catria chain and the eastern culminating in Monte San Vicino. On the whole of the east side of the Sibilline Mountains, one of the principal constituents of the Central Apennines, there has been a gigantic subsidence, the face of the rupture showing a sheer vertical altitude of some 6500 ft. The culminating peaks of this constituent range reach an altitude of 8125 ft. in Monte de Pretara and 8010 ft. in Monte Vettore. There are snow-fields on various peaks of the Gran Sasso d'Italia, the next (going south) constituent chain of the Central Apennines, as on Monte Corno (above 8530 feet), on Pizzo Intermele (above

8585 ft.), and on Monte Corvo (above 8550 ft.); and it is on the same chain, or rather mountain-knot, that the only glaciers, though in a rudimentary form, occur in the Apennines. They lie in the high valleys above the sources of the Arno, at altitudes of 5400 ft. and upwards, and in the valleys which feed the Venaquaro (*i.e.*, the Vomano), at altitudes of 6400 ft. and above. It may be mentioned that the last surviving chamois on the Gran Sasso is believed to have been shot in 1880. Monte Amaro, the culminating peak of the Majella Mountains, the next constituent chain, reaches an altitude of 9170 ft. Except for small quantities of anthracite and sulphur, the Apennines contain no minerals, but possess several mineral springs, of which the best known are those at Lucca, Montecatini, San Casciano, Porretta, and Telese. In very many cases the valleys on the east of the Apennines differ from those on the west, in that they are not only shorter, but run transversely to the main axis of the system; whereas, on the west or Mediterranean side, they frequently lie parallel to the axis. The most notable examples of the latter are the upper valleys of the Arno and the Tiber. Above 3000 ft. the Apennines are in general bare and barren of vegetation, except for a little scrub and some scanty pasture in summer; but below that limit their slopes are as a rule the reverse, being well planted with vines, olives, chestnuts, orange, citron, and other fruit trees, besides yielding the usual crops. Of the Apennine lakes, Lake Fucino was drained and made amenable to cultivation in 1876, after more than twenty years' labour, and Lake Trasimeno was provided with a second outlet in 1896-98. The project of draining the latter, originally suggested by Napoleon I., has been repeatedly under consideration, but as yet has come to nothing. The lakes of Bolsena, Vico, Bracciano, and Albano lie west of the main chain, and are volcanic-crater lakes. The central ranges of the Apennines exercise, as might be expected, an important influence upon the local climatic conditions on both the Adriatic and Atlantic versants. One consequence of their position is that the extremes of temperature diminish as one descends towards the coast, as well as proceeds towards the south. On the Adriatic side, that is, in the provinces of Emilia (part), Umbria, the Marches, and the Abruzzi, the annual mean does not exceed 57° F., the January mean 38.1°, or the July mean 75.2°. The difference between the absolute maximum of 100.4° (at Forlì) and the absolute minimum of 5° (at Camerino) amounts to 95.4°. The higher parts, as represented by Urbino (1481 ft. above sea-level) and Camerino (2177 ft.), have naturally a lower annual mean (53°) than places near the coast, such as Forlì (163 ft.), Jesi (332 ft.), and Ancona (52 ft.), whose annual mean is 59.6°. On the Mediterranean side the annual mean is somewhat higher than the general mean of the Adriatic side, namely, 57.7° (Perugia, at 1706 ft., having a mean of 55.2°, and Leghorn, at 78 ft., 59.7°); but the January mean is appreciably higher, namely, 41.5°, though the July mean is practically the same, 75.4°. The range between the extremes—105.1° at Florence and 12.2° also at Florence—is also less, namely, 92.9°. Farther south, in Apulia, Basilicata, and Calabria, the annual mean is 58.1° (Potenza, 2711 ft., 50.2°; Lecce, 236 ft., 61.9°); the January mean, 42.9°; and the July mean, 75.1°. The extremes lie at 93.9° (Lecce), and 13.6° (Potenza). The heaviest rainfall occurs as a rule in the higher mountainous parts; for instance, at Urbino, an average of 39½ inches falls annually (period of observations, 43 years); at Camerino, 38½ in. (47 years); at Siena, 30½ in. (55 years); at Florence, 34½ in. (65 years); and at Cosenza, 42 in. (19 years). But to this there are some exceptions; for instance, at Aquila, under the shelter of the Gran Sasso, the annual average is only 25½ in. (20 years); and

at Potenza, in the valley of the Basento, it is 24 in. (15 years). On the west side of the peninsula the rainfall is relatively heavier than on the east: at Rome, 30½ in. (69 years); and Naples, 32 in. (73 years); as compared with 26½ in. at Ancona (30 years), and 23 in. at Lecce (19 years). The main chain of the Apennines is now crossed or pierced by a dozen railway lines, e.g., by the line from Genoa to Alessandria, Savoua to Turin, Spezia to Parma, Pistoja to Bologna, Ancona to Rome, the Sulmona-Pescara line, Naples to Foggia, Salerno to Tarento, and others. The inhabitants of the once inaccessible Abruzzis have

now almost entirely abandoned their brigand habits, and are taking to the breeding of silkworms and the spinning of silk. Many of them, being still desperately poor, emigrate every summer as labourers to the big estates of the Agro Romano, between the Tiber and Civitavecchia.

See PARTSCH, in *Verhandlungen d. Ges. f. Erdkunde zu Berlin*, vol. i. (1889).—MARINELLI, in *Atti of the first Italian Geog. Congress*, vol. ii. 2, pp. 637 *et seq.*; GLOBUS, vol. lxxvi. (1899); and for the meteorology, *Annuario Statistico Italiano*, 1895 (Rome, 1896). (J. T. BE.)

APOCALYPTIC AND APOCRYPHAL LITERATURE.

THE apocalyptic and apocryphal books of Scripture have been generally treated under two distinct heads, but such a method is certainly unadvisable, since the former literature constitutes in reality a subdivision of the latter. For a general introduction to both these literatures the reader should consult *Ency. Brit.* ii. 174-184; *Ency. Biblica*, i. 213-215, 249-250; Hastings' *Dictionary of the Bible*, i. 109-123; Kautzsch, *Apokryphen u. Pseudepigraphen*, i. pp. xi-xxiii.

Biblical Apocrypha.—These books will be dealt with under their appropriate heads. They stand in the English Bible in the following order:—1 Esdras, 2 Esdras, Tobit, Judith, Additions to Esther, Wisdom of Solomon, Ecclesiasticus, Baruch, Epistle of Jeremy, Additions to Daniel (Song of the Three Holy Children, History of Susannah, and Bel and the Dragon), Prayer of Manasseh, 1 Maccabees, 2 Maccabees. It is hardly possible to form any classification which is not open to some objection. In

any case the classification must be to some extent provisional, since scholars are still divided as to the original language, date, and place of composition of some of the books which must come under our classification.¹ In the first place, we must treat separately the Old Testament and the New Testament literature of this nature. In the next place we must discriminate (I.) the Palestinian and (II.) the Hellenistic literature of the Old Testament. The former was generally written in Hebrew or Aramaic, and seldom in Greek; the latter naturally in Greek. Next, within these literatures we shall distinguish three or four classes according to the nature of the subject with which they deal. Thus the books of which we have to treat will be classed as—(i.) Historical, (ii.) Legendary (Haggadic), (iii.) Apocalyptic, (iv.) Sapiential, or belonging to the Wisdom Literature.

OLD TESTAMENT APOCALYPTIC AND APOCRYPHAL LITERATURE.

<p>I.—PALESTINIAN JEWISH LITERATURE.</p> <p>(i.) <i>Historical.</i></p> <p>1 Esra. 1 Maccabees. History of Johannes Hyrcanus.</p> <p>(ii.) <i>Legendary.</i></p> <p>Book of Baruch. Rest of the Words of Baruch. Martyrdom of Isaiah. Book of Jubilees. Judith. Pseudo-Philo's Liber Antiquitatum. Book of Adam. Jannes and Jambres. Joseph and Asenath.</p>	<p>(iii.) <i>Apocalyptic.</i></p> <p>Apocalypse of Abraham. Apocalypse of Baruch. Ethiopic Book of Enoch. 4 Esra. Assumption of Moses. Book of Noah. Testament of the XII Patriarchs. Psalms of Solomon. Prayer of Joseph. Book of Eldad and Modad. Apocalypse of Elijah. Apocalypse of Zephaniah.</p> <p>(iv.) <i>Wisdom Literature.</i></p> <p>Pirke Aboth. Sirach.</p>
--	---

¹ Thus some of the additions to Daniel and the Prayer of Manasseh are most probably derived from a Semitic original written in Palestine, yet in compliance with the prevailing opinion they are classed under Hellenistic Jewish literature. Again, the Slavonic Enoch goes back undoubtedly in parts to a Semitic original, though most of it was written by a Greek Jew in Egypt.

II.—HELLENISTIC JEWISH LITERATURE.

(i.) *Historical and Legendary.*

Additions to Daniel.
Additions to Esther.
Epistle of Jeremy.
2 Maccabees.
3 Maccabees.
Prayer of Manasseh.
Tobit.

(ii.) *Apocalyptic.*

Slavonic Enoch.
Oracles of Hystaspes.
Testament of Job.
Testaments of the III Patriarchs.
Sibylline Oracles.

(iii.) *Wisdom Literature.*

4 Maccabees.
Wisdom of Solomon.

I.—PALESTINIAN JEWISH LITERATURE.

(i.) *Historical.*

1 *Esra* or *Esdras*.—This book called *Ἐσδρας α'* in the LXX. and "Liber tertius Esdræ" in the Vulgate, (see *Ency. Brit.* viii. 541-542) may safely be regarded as a translation from a Hebrew-Aramaic original with the exception of the independent section iii. 1-v. 6, which is probably from the Greek (see Nestle, *Marginalien und Materialien*, 1893, pp. 23-29; Thackeray in Hastings' *Bible Dict.* i. 758-763; Volz in *Ency. Biblica*, ii. 1488-1494). Since, with the above-named exception, this book is an early translation from a text superior in many instances to that of the canonical books of 2 Chronicles, Esra, and Nehemiah, so far as these deal with the rebuilding of the temple, it is of no little value in the critical emendation of the texts of those books (Driver, *Introd. to Literature of O.T.* p. 554). Gwynn and Thackeray adduce some grounds for the view that this translation and that of the LXX. of Daniel are from the same hand (see *Dict. Christ. Biog.* iv. 977 note). Sir H. Howorth's opinion (*The Academy*, 1893, pp. 13, 60, 106, 174, 326, 524) that this book is more trustworthy than the canonical Esra has much to be said in its favour. Its date is very uncertain. Schürer contents himself with saying that its composition must be placed before the time of Josephus. Fritzsche declares that it cannot be earlier than the 1st century B.C. (so Ewald, De Wette).

1 *Maccabees*.—To the account of this work in *Ency. Brit.* xv. 131, it will not be necessary to add more than a few facts. The general credibility of the book is recognized by recent as well as by earlier research. Willrich (*Juden und Griechen vor der Makkab. Erhebung*, 1895) has given good grounds for assuming that the thirteen letters reproduced in the book have been added by its Greek translator from a collection of such authorities in Jerusalem.

Greek MSS. and Texts.—The following MSS. contain 1 Maccabees: α, A, Codex Venetus, and 15 cursives. There are several editions of the text. The textus receptus is found in the Sixtine edition of the LXX. 1587, which is based on the Cod. Venetus and on certain unnamed cursives. This text is followed by Parsons and Holmes (*Vetus Testamentum Græce*, 5 vols. 1798-1827), who append the variants of 15 cursives, and Tischendorf (*V. T. Græce*, 2 vols. 1887). Fritzsche (*Libri apoc. V. T.* 1871) gives an independent text based on α, A, Cod. Ven. and the cursives in Parsons and Holmes's edition. Finally Swete prints A with variants from α and Cod. Ven. (*The Old Testament in Greek according to the Septuagint*, 3 vols. 1887-94).

Syriac and Latin Versions.—There is no ancient Ethiopic version, but there are Syriac and Latin versions. The Syriac appears in two forms: the first is that in the Peshitto from the Greek text of Lucian (preserved in the cursives 19, 64, 93); the second is that published by Ceriani, from a 6th-century MS. The latter agrees more closely with the Greek, and is probably the result of a revision of the older text with the help of a Greek text (see G. Schmidt, *Zeitschrift. f. d. ältest. Wissensch.* 1897, xvii. 1-47, 233-262). There are also two forms of the old Latin version: the first is that of the Vulgate, and the second is found in a Complutensian MS. in the Milan Library.

Translations and Commentaries.—The most trustworthy English translations are those in the Variorum Bible and in the Revised Version, and the best commentaries those of Rawlinson in the *Speaker's Apocrypha* and Fairweather and Black, *The First Book of Maccabees*, 1897. In German there is nothing equal to Kautzsch's translation (*Apok. und Pseud.* 1900, i. 24-81) and to Grimm's *Das erste Buch der Maccabäer erklärt*, 1853. On the literature generally see Schürer, *Gesch. d. Jüd. Volkes*³, iii. 141-146.

History of Johannes Hyrcanus.—This work is mentioned in 1 Macc. xvi. 23, 24, but no trace of its existence has been discovered elsewhere.

(ii.) *Legendary or Haggadic Works.*

Book of Baruch.—Recent criticism has in some respects diverged from the account of this book in *Ency. Brit.* iii. 404-405. Thus most scholars, such as Fritzsche, Hitzig, Kneucker, Hilgenfeld, Reuss, agree in assuming that i.-iii. 8 and iii. 9-v. 9 are from distinct writers. But some critics have gone further. Thus Rothstein (Kautzsch, *Apok. und Pseud.* i. 213-215) holds that there is no unity in iii. 9-v. 9, but that it is composed of two independent writings—iii. 9-iv. 4 and iv. 5-v. 9. Marshall (*Hastings' Bible Dict.* i. 251-254) gives a still more complex analysis. He finds in it the work of four distinct writers—i. 1-14, i. 15-iii. 8, iii. 9-iv. 4, iv. 5-v. 9. Though most modern writers, as Cornill, Gifford, Schürer, &c., advocate a Hebrew original of i.-iii. 8 and a Greek original of the rest, Rothstein, Kneucker, and König hold fast to the view of the older exegesis that the whole book is derived from the Hebrew. Marshall, on the other hand, argues for the view that i.-iii. 8 is translated from the Hebrew, iii. 9-iv. 4 from the Aramaic, and that iv. 5-v. 9 was originally written in Greek.

Commentaries, &c.—In addition to those enumerated in *Ency. Brit.* iii. 405, the more valuable of the more recent works is Kneucker's *Das Buch Baruch*, 1879; Gifford's in *Speaker's Apoc.* ii.

Date.—The dates of the various constituents of this book are quite uncertain. Ewald, followed by Gifford and Marshall, assigns i.-iii. 8 to the period after the conquest of Jerusalem by Ptolemy I. in 320 B.C.; Reuss to some decades later; and Fritzsche, Schrader, Keil, to the times of the Maccabees. Hitzig, Kneucker, and Schürer assume that it was written after A.D. 70. Ryle and James (*Psalms of Solomon*, pp. lxxii.-lxxvii.) hold that iv. 31-v. 9 is dependent on the Greek version of Ps. xi., and that accordingly Baruch was reduced to its present form after A.D. 70.

Rest of the Words of Baruch.—This book is most probably of Jewish authorship and its present form due to a Christian hand, as Kohler (*Jewish Quarterly Review*, 1893, pp. 407-419) has shown. It has been preserved in Greek, Ethiopic, Armenian, and Slavonic (see Schürer³, iii. 286, 287). The Greek was first printed at Venice in 1609, and next by Ceriani in 1868 under the title "Paralipomena Jeremiæ" in his *Monumenta Sacra*, v. 11-18, and by Rendel Harris in 1889. Harris regards it in its present form as an Eirenicon addressed to the Jews by a Christian after the rebellion of Bar-Cochba.

Martyrdom of Isaiah.—This Jewish work has been in part preserved in the *Ascension of Isaiah*. To it belong i. 1, 2^a, 6^b-13^a; ii. 1-8, 10-iii. 12; v. 1^a-14 of that book. It is of Jewish origin, and recounts the martyrdom of Isaiah at the hands of Manasseh. For the Christian elements of the *Ascension of Isaiah*, see "Testament of Hezekiah" and "Vision of Isaiah."

Original Language and Date.—This was most probably written in Hebrew or Aramaic, but there is not sufficient evidence to determine this question definitely. As regards the date we may safely conclude that it was written not later than the 1st century A.D. Thus it was well known to Origen (*Ep. ad Africanum*, ix., Lommatzsch, xvii. 31; *In Matt.* xxiii. 37, Lommatzsch, iv. 237, &c.). Still earlier it was known to Tertullian (*De Pat.* 14) and to Justin Martyr (*Dial. c. Tryph.* cxx.). Thus it was current early in the 2nd century. It was probably known to the writer of the Epistle to the Hebrews (xi. 37). This brings us, if the last reference is trustworthy, to the 1st century A.D., and this no doubt is the right date, for it is highly improbable that Jewish writings of the 2nd century should gain currency in the Christian Church.

Greek Version.—The Greek version, as edited in the *Ascension*, has in part been just recovered and published by Grenfell and Hunt (*Amherst Papyri*, 1900, i. 1-22); see also Charles, *Ascension of Isaiah*, 1900, pp. xxii.-xxxiii. 84-95), where this text is critically edited and compared with all other existing authorities. This martyrdom was known to the writer of the *Opus Imperfectum* (see Montfaucon's edition of Chrysostom, vi. pp. xx. xxi.) in its original form before it was incorporated in the *Ascension* (see Charles, *op. cit.* pp. xl.-xliii., xlv. 8, 9).

Ethiopic Version.—This was first edited by Laurence in 1819 from one MS., in 1877 by Dillmann from three (*Ascensio Isaiæ Ethiopice et Latine*), and in 1900 by Charles from a more accurate collation of the same three MSS., together with the other versions. This version admirably represents the original. Two of the three MSS. are excellent.

Latin Version.—Of this ii. 14-iii. 13 was discovered and edited in 1828 by Mai. This was reprinted by Dillmann in 1877 in his edition of the *Ascension*, and in 1900 by Charles after a fresh collation of the Vatican palimpsest. On the relation of the various versions, see Charles, pp. xviii.-xxxiii.

Modern Translations.—Besides Laurence's Latin and English translations, which are not trustworthy, there are Dillmann's Latin translation, Bassett's French (*L'ascension d'Isaïe*, 1894), Beer's German (*Apok. und Pseud.* ii. 124-127), and Charles's English (*op. cit.* pp. 1-18, 40-42). For bibliography, see also Schürer, *Gesch. des Jüd. Volkes*³, iii. 284-285.

Jubilees.—This book is variously entitled τὰ Ἰωβηλαία, οἱ Ἰωβηλαῖοι, ἡ λεπτή Γένεσις, τὰ λεπτά Γενέσεως, Μικρογένεσις in Greek, and "The Book of the Division" in Ethiopic. It is really an Haggadic commentary on Genesis, and is practically the sole monument of legalistic Pharisaism belonging to the latter half of the 2nd century B.C., and is a characteristic example of that form of religion against which the Pauline dialectic was directed (see *Ency. Brit.* ii. 176-177). It has a secret apologetic aim. It defends and justifies the assumption of the high priesthood by the Maccabees.

Original Language.—This book, as the production of a strict Pharisee, was naturally written in Hebrew. This Hebrew was not free from Aramaic forms, as we infer from the formation of the proper name "Mastema" and from the statement of Jerome (*Ep. ad Fabiol.* 78; *mansionem*, 18). On the other hand, a large number of passages cannot be intelligibly translated unless on the presupposition of a Hebrew original (see Charles, *Ethiopic Version of Hebrew Book of Jubilees*, pp. ix. x.; Littmann in Kautzsch's *Apok. und Pseud.* ii. 34, 35). Fragments of the original Hebrew are still found in certain Midrashim.

Versions: Greek, Syriac, Ethiopic, and Latin.—Large fragments of the Greek version have come down to us in Epiphanius and such annalists as Syncellus and Cedrenus. Only a few lines survive of the Syriac. Both these were made from the original. As regards the two latter versions, which are derived from the Greek, the whole of the Ethiopic survives and about one-fourth of the Latin. The latter was first published by Ceriani in 1861, next by Rönisch (*Das Buch der Jubiläen*) in 1874, and by Charles in his edition of the Ethiopic text.

Ethiopic Text and Translations.—This text was first edited by Dillmann from two MSS. in 1859, and in 1895 by Charles from four. In the latter edition, the Greek and Latin fragments are printed together with the Ethiopic. The book was translated into German by Dillmann from one MS. in Ewald's *Jahrbücher*, ii. iii. 1850, 1851, and by Littmann (in Kautzsch's *Apok. und Pseud.* ii. 39-119) from Charles's Ethiopic text; in English by Schodde (*Bibl. Sacra*, 1885) from Dillmann's text, and by Charles (*Jewish Quarterly Review*, Oct. 1893, July 1894, Jan. 1895) from the text afterwards published in 1895.

Date and Author.—Jubilees was written after 135 B.C., when J. Hyrcanus became ecclesiastical and civil head of the nation, and before 95 B.C., when the entire body of the Pharisees was at strife with his successor Jannäus (see Bousset, *Zeitschr. f. NT-*

liche Wissenschaft, 1900, pp. 198-201). The author was not a Hellenistic Jew, as Frankel supposes, nor a Samaritan, as Beer thought, nor yet an Essene, but essentially a Pharisee in the most rigorous sense of the term (see *Ency. Biblica*, i. 232; Kautzsch, *op. cit.* ii. 36-37).

Bibliography.—See *Ency. Brit.* ii. 177; Schürer, *Gesch. d. Jüd. Volkes*, iii. 277-280. The first commentary on the whole text, by Charles, was published in 1902.

Judith.—This book (see *Ency. Brit.* xiii. 765-766) was written originally in Hebrew. This is shown not only by the numerous Hebraisms, but also by mistranslations of the Greek translation, as in ii. 2, iii. 9, and other passages (see Fritzsche and Ball *in loc.*), despite the statement by Origen (*Ep. ad Afric.* 13) that the book was not received by the Jews among their apocryphal writings. In his preface to Judith, Jerome says that he based his Latin version on the Chaldee, which the Jews reckoned among their Hagiographa. Ball (*Speaker's Apocrypha*, i. 243) holds that the Chaldee text used by Jerome was a free translation or adaptation of the Hebrew. The book exists in two forms. The shorter, which is preserved only in Hebrew (see under *Hebrew Midrashim* below), is, according to Scholz, Lipsius, Ball, and Gaster, the older. The longer form is that contained in the versions.

Greek Version.—This is found in three recensions: (1) in A B, κ ; (2) in codices 19, 108 (Lucian's text); (3) in cod. 58, the source of the old Latin and Syriac.

Syriac and Latin Versions.—Two Syriac versions were made from the Greek—the first, that of the Peshitto; and the second, that of Paul of Tella, the so-called Hexaplaric. The Old Latin was derived from the Greek, as we have remarked above, and Jerome's from the Old Latin, under the control of a Chaldee version.

Later Hebrew Midrashim.—These are printed in Jellinek's *Bet ha-Midrash*, i. 130-131; ii. 12-22; and by Gaster in *Proceedings of the Society of Biblical Archaeology*, 1894, pp. 156-163.

Date.—The book in its fuller form was most probably written in the 1st century, before the Christian era. The writer places his romance three centuries earlier, in the time of Ochus, as we may reasonably infer from the attack made by Holofernes and Bagoas on Judæa; for Artaxerxes Ochus made an expedition against Phœnicia and Egypt in 350 B.C., in which his chief generals were Holofernes and Bagoas.

Recent Literature.—Ball, *Speaker's Apocrypha*, 1888, an excellent piece of work; Scholz, *Das Buch Judith*², 1896; Löhr, *Apok. und Pseud.* 1900, ii. 147-164; Porter in *Hastings' Bible Dict.* ii. 822-824; Gaster, *Ency. Biblica*, ii. 2642-2646. See Ball, pp. 260-261, and Schürer, *in loc.*, for a full bibliography.

Pseudo-Philo's Liber Antiquitatum Biblicarum.—Though the Latin version of this book was thrice printed in the 16th century (in 1527, 1550, and 1599), it was practically unknown to modern scholars till it was recognized by Conybeare and discussed by Cohn in the *Jewish Quarterly Review*, 1898, pp. 279-332. It is an Haggadic revision of the Biblical history from Adam to the death of Saul. Its chronology agrees frequently with the LXX. against that of the Massoretic text, though conversely in a few cases. The Latin is undoubtedly translated from the Greek. Greek words are frequently transliterated. While the LXX. is occasionally followed in its translation of Biblical passages, in others the Massoretic is followed against the LXX., and in one or two passages the text presupposes a text different from both. On many grounds Cohn infers a Hebrew original. The eschatology is similar to that taught in the similitudes of the Book of Enoch. In fact, Eth. En. li. 1 is reproduced in this connexion. Prayers of the departed are said to be valueless. The book was written after A.D. 70; for, as Cohn has shown, the exact date of the fall of Herod's temple is predicted.

Lost Legends.—The Adam Books.—That there was a Jewish book or books of Adam, which recounted the life of Adam and Eve after the Fall, we must conclude from the host of Christian apocrypha which have this subject for their theme. These are found in Greek, Syriac,

Ethiopic, Arabic, Armenian. A Jewish book of Adam is mentioned in the Talmud and likewise in the *Constitutiones Apost.* vi. 16. See *Smith's Dictionary of Christian Biography*, i. 34-39; *Ency. Bibl.* i. 253; Schürer, *Gesch. d. Jüd. Volkes*, iii. 287-289.

Jannes and Jambres.—These two men are referred to in 2 Tim. iii. 8 as the Egyptian magicians who withstood Moses. The book which treats of them is mentioned by Origen (*ad Matt.* xxiii. 37 and xxvii. 9 [*Jannes et Mambres Liber*]), and in the Gelasian Decree as the *Peenitentia Jamnis et Mambre*. The names in Greek are generally $\text{Ἰαννῆς καὶ Ἰαμβρῆς}$ (= יַנַּיִם וַיִּמְרִים) as in the Targ.-Jon. on Exod. i. 15; vii. 11. In the Talmud they appear as יַנַּיִם וַיִּמְרִים. Since the western text of 2 Tim. iii. 8 has Μαμβρῆς , Wescott and Hort infer that this form was derived from a Palestinian source. These names were known not only to Jewish but also to heathen writers, such as Pliny and Apuleius. The book, therefore, may go back to pre-Christian times. (See Schürer², iii. 292-294; *Ency. Biblica*, ii. 2327-2329.)

Joseph and Asenath.—The statement in Gen. xli. 45, 50 that Joseph married the daughter of a heathen priest naturally gave offence to later Judaism, and gave rise to the fiction that Asenath was really the daughter of Shechem and Dinah, and only the foster-daughter of Potipherah (*Targ.-Jon.* on Gen. xli. 45; Tractat. *Sopherim*, xxi. 9; *Talkut Shimoni*, c. 134. See Oppenheim, *Fabula Josephi et Aseethae*, 1886, pp. 2-4). Origen also was acquainted with some form of the legend (*Selecta in Genesin*, ad Gen. xli. 45, ed. Lommatzsch, viii. 89-90). The Christian legend, which is no doubt in the main based on the Jewish, is found in Greek, Syriac, Armenian, Slavonic, and mediæval Latin. Since it is not earlier than the 3rd or 4th century, it will be sufficient here to refer to *Smith's Dict. of Christ. Biog.* i. 176-177; *Hastings' Bible Dict.* i. 162-163; Schürer, iii. 289-291.

(iii.) Apocalyptic Literature.

Apocalypse of Abraham.—This book is found only in the Slavonic (edited by Bonwetsch, *Studien zur Geschichte d. Theologie und Kirche*, 1897), a translation from the Greek. It is of Jewish origin, but in part worked over by a Christian reviser. The first part treats of Abraham's conversion, and the second forms an apocalyptic expansion of Gen. xv. This book was possibly known to the author of the *Clem. Recognitions*, i. 32, a passage, however, which may refer to Jubilees. It is most probably distinct from the ἀποκάλυψις Ἀβραάμ used by the Gnostic Sethites (Epiphanius, *Hær.* xxxix. 5), which was very heretical. On the other hand, it is probably identical with the apocryphal book Ἀβραάμ mentioned in the Stichometry of Nicephorus, and the Synopsis Athanasii, together with the Apocalypses of Enoch, &c.

Syriac Apocalypse of Baruch.—This apocalypse has survived only in the Syriac version, of which Ceriani discovered a 6th-century MS. in the Milan Library. Of this he published a Latin translation in 1866 (*Monumenta Sacra*, I. ii. 73-98), which Fritzsche reproduced in 1871 (*Libri Apocryphi V. T.* pp. 654-699), and the text in 1871 (*Mon. Sacra*, V. ii. 113-180), and subsequently in photo-lithographic facsimile in 1883. Chaps. lxxviii.-lxxxvi., indeed, of this book have long been known. These constitute Baruch's epistle to the nine and a-half tribes in captivity, and have been published in Syriac and Latin in the London and Paris Polyglots, and in Syriac alone from one MS. in Lagarde's *Libri V. T. Apocryphi Syr.* 1861; and by Charles from ten MSS. (*Apocalypse of Baruch*, 1896, pp. 124-167). The entire

book was translated into English by the last-named writer (*op. cit.* pp. 1-167), and into German by Ryssel (Kautzsch's *Apok. und Pseud.* 1900, ii. pp. 413-446). The Syriac is translated from the Greek; for Greek words are occasionally transliterated, and passages can be explained only on the hypothesis that the wrong alternative meanings of certain Greek words were followed by the translator. The Greek in turn is derived from the Hebrew, for unintelligible expressions in the Syriac can be explained and the text restored by retranslation into Hebrew. Many *paronomasiae* discover themselves in the course of such retranslation (see Charles, *Apoc. Bar.* pp. xliv.-liii.). The necessity of postulating a Hebrew original was first shown by the present writer, and has since been maintained by Wellhausen (*Skizzen u. Vorarbeiten*, vi. 234) and by Ryssel (*Apok. und Pseudepig. A. T.* 1900, ii. 411). The final editor of the work writes in the name of Baruch, the son of Neriah. The time extends from the eve of the capture of Jerusalem by the Chaldees till after its accomplishment. If the letter to the tribes in captivity (lxxviii.-lxxxvi.) be disregarded, the book falls into seven sections separated by fasts, save in one case (after xxxv.) where the text is probably defective. These sections, which are of unequal length, are—(1) i.-v. 6; (2) v. 7-viii.; (3) ix.-xii. 4; (4) xii. 5-xx.; (5) xxi.-xxxv.; (6) xxxvi.-xlvi.; (7) xlvii.-lxxvii. These treat of the Messiah and the Messianic kingdom, the woes of Israel in the past and the destruction of Jerusalem in the present, as well as of theological questions relating to original sin, free will, works, the number of the saved, the nature of the resurrection body, &c. The views expressed on several of the above subjects are often conflicting. In one class of passages there is everywhere manifest a vigorous optimism as to Israel's ultimate well-being on earth, and the blessedness of the chosen people in the Messianic kingdom is sketched in glowing and sensuous colours (xxix., xxxix.-xl., lxiii.-lxxiv.). Over against these passages stand others of a hopelessly pessimistic character, wherein, alike as to Israel's present and future destiny on earth, there is written nothing save "lamentation, and mourning, and woe." The world is a scene of corruption, its evils are irremediable, its end is nigh, and the advent of the new and spiritual world at hand. The first to draw attention to the composite elements in this book was Kabisch (*Jahrbücher f. protest. Theol.* 1891, pp. 66-107). This critic regarded xxiv. 3-xxix., xxxvi.-xl., and liii.-lxxiv. as independent sources written before the fall of Jerusalem, A.D. 70, and his groundwork, which consists of the rest of his book, with the exception of a few verses, as composed after that date. All these elements were put together by a Christian contemporary of Papias. Many of these conclusions were arrived at independently by a French scholar, De Faye (*Les Apocalypses Juives*, 1892, pp. 25-28, 76-103, 192-204). The present writer (*Apocalypse of Baruch*, 1896, pp. liii.-lxvii.), after submitting the book to a fresh study, has come to the following conclusions:—The book is of Pharisaic authorship and composed of six independent writings—A¹, A², A³, B¹, B², B³. The first three were composed when Jerusalem was still standing and the Messiah and the Messianic kingdom were expected: A¹, a mutilated apocalypse=xxvii.-xxx. 1; A², the Cedar and Vine Vision=xxxvi.-xl.; A³, the Cloud Vision=liii.-lxxiv. The last three were written after A.D. 70, and probably before 90. Thus B³=lxxxv. was written by a Jew in exile, who, despairing of a national restoration, looked only for a spiritual recompense in heaven. The rest of the book is derived from B¹ and B², written in Palestine after A.D. 70. These writings belong to very different types of thought. In B¹ the earthly Jerusalem is to be rebuilt, but not so in B²: in the former the exiles are to be restored, but not in the latter; in the former a Messianic kingdom without a Messiah

is expected, but no earthly blessedness of any kind in the latter, &c. B¹=i.-ix. 1, xxxii. 2-4, xliii.-xliv. 7, xlv.-xlii., lxxvii.-lxxxii., lxxxiv., lxxxvi.-lxxxvii. B²=ix.-xxv., xxx. 2-xxxv., xli.-xlii., xlv. 8-15, xlvii.-lii., lxxv.-lxxvi., lxxxiii.

The above critical analyses were attacked and rejected by Clemen (*Stud. und Krit.* 1898, 211 *sqq.*). He fails, however, in many cases to recognize the difficulties at issue, and those which cannot be ignored he sets down to the conflicting apocalyptic traditions on which the author was obliged to draw for his subject-matter. Though Ryssel (Kautzsch, *Apok. u. Pseud. des A. T.* ii. 409) has followed Clemen, neither has given any real explanation of the disorder of the book as it stands at present.

Relation to 4 Ezra.—The affinities of this book and 4 Ezra are so numerous (see Charles, *op. cit.* 170-171) that Ewald and Ryle assumed identity of authorship. But their points of divergence are so weighty (see *op. cit.* pp. lxxix.-lxxxi.) that this view cannot be sustained. Three courses still remain open. If we assume that both works are composite, we shall perforce admit that some of the constituents of 4 Ezra are older than the latest of Baruch and that other constituents of Baruch are decidedly older than the remaining ones of 4 Ezra. On the other hand, if we assume unity of authorship, it seems impossible to arrive at finality on the chronological relations of these two works. Langen, Hilgenfeld, Wieseler, Stähelin, Renan, Hausrath, Drummond, Dillmann, Rosenthal, Gunkel, have maintained on various grounds the priority of 4 Ezra; and Schürer, Bissell, Thomson, Deane, Kabisch, De Faye, Wellhausen, and Ryssel the priority of Baruch on grounds no less convincing.

Integrity of the Book.—In lxxvii. 19 it is said that Baruch wrote two epistles, one to the nine and a-half tribes and the other to the two and a-half at Babylon. The former is found in lxxviii.-lxxxvi.; the latter is lost, but is probably preserved either wholly or in part in the Book of Baruch, iii. 9-iv. 29 (see Charles, *op. cit.* pp. lxxv.-lxxvii.). On the other hand, it is not necessary to infer from lxxv. that an account of Baruch's assumption was to be looked for in the book.

Literature.—In addition to the works cited above, see Rosenthal, *Vier apokryphische Bücher*, 1885, pp. 72-103; Deane, *Pseudepigrapha*, 1891, pp. 130-162. For a full bibliography see Schürer, *Gesch. d. Jüd. Volkes*, 1898, iii. 223-232, and Charles (*op. cit.* pp. xxx.-xlii.).

Ethiopic Book of Enoch.—This is the most important of all the apocryphal or pseudepigraphal writings for the history of religious thought (see Charles, *Book of Enoch*, 33-53, 312-317, *Eschatology: Hebrew, Jewish, and Christian*, 1899, pp. 182-192, 203-219). It is quoted by name as a genuine production in the Epistle of Jude 14 *sq.*, and it lies at the base of Matt. xix. 28 and John v. 22, 27, and other passages. It had also a vast indirect influence on the Palestinian literature of the 1st century of our era. Like the Pentateuch, the Psalms, the Megilloth, the Pirke Aboth, this work was divided into five parts, with the critical discussion of which we shall deal below. Modern scholars are agreed that Enoch was originally written in Hebrew or Aramaic. Halévy, *Journal Asiatique*, 1867, pp. 352-395, is in favour of the former view; but the latter is now more generally advocated on the ground of Aramaic forms in the Gizeh Greek fragment, *φουκα*, xviii. 8, from *μαυδοβαρα* in xxviii. 1, and *βαβδηρα* in xxix. 1, from *קרבך* and *χρονβεν* in xiv. 11, 18. On the other hand, it must be remembered that some Aramaic forms are found in the LXX. and in the Ethiopic version of the Old Testament. Hence, in the face of the powerful arguments of Halévy for a Hebrew original, the question cannot be regarded as yet settled. The Semitic original was translated into Greek. It is not improbable that there were two distinct Greek versions. Of the one several fragments have been preserved in Syncellus (A.D. 800), vi.-ix. 4, viii. 4-x. 14, xv. 8-xvi. 1; of the other i.-xxxii. in the Gizeh Greek fragment discovered in Egypt and published by Bouriant, *Fragments grecs du livre d'Enoch*, in 1892, and subsequently by Lods, Dillmann, Charles, Swete, and finally by Flemming and Radermacher. In addition to these fragments there is that of lxxxix. 42-49 (see Gildemeister in the *ZDMG*, 1855, pp. S. I.—62

621-622, and Charles, *op. cit.* 238-240). Of the Latin version only i. 9 survives, being preserved in the Pseudo-Cyprian's *Ad Novatianum* and cvi. 1-18 discovered by James in an 8th-century MS. of the British Museum (see James, *Apoc. Anecdota*, 146-150, Charles, *op. cit.* 372-375). This version is made from the Greek. The Ethiopic version, which is a very faithful translation of the Greek, alone preserves the entire text. It was edited by Laurence in 1838 from one MS. and in 1851 by Dillmann from five. The present writer has undertaken a text based on a study of twenty-five MSS.

Translations and Commentaries.—Laurence, *The Book of Enoch*, Oxford, 1821; Dillmann, *Das Buch Henoch*, 1853; Schodde, *The Book of Enoch*, 1882; Charles, *The Book of Enoch*, 1893; Beer, "Das Buch Henoch" in Kautzsch's *Apok. u. Pseud. des A. T.* 1900, ii. 217-310; Flemming and Radermacher, *Das Buch Henoch*, 1901. *Critical Inquiries.*—The Bibliography will be found in Schürer, *Gesch. d. Jüdischen Volkes*, iii. 207-209, and a short critical account of the most important of these in Charles, *op. cit.* pp. 9-21.

We have remarked above that the *Book of Enoch* is divided into five parts—i.-xxxvi., xxxvii.-lxxi., lxxii.-lxxxii., lxxxiii.-xc., xci.-cviii. Some of these parts constituted originally separate treatises. In the course of their reduction and incorporation into a single work they suffered much mutilation and loss. From an early date the compositeness of this work was recognized. Scholars have varied greatly in their critical analyses of the work (see Charles, *op. cit.* 6-21, 309-311; Hastings' *Dict. of the Bible*, i. 706; *Ency. Biblica*, i. 221-222; Schodde, *Book of Enoch*, 1882, pp. 19-32). The analysis which gained most acceptance was that of Dillmann (Herzog's *Real Enkyl.* xii. 350-352), according to whom the present books consist of—(1) the groundwork, *i.e.*, i.-xxxvi., lxxii.-cv., written in the time of John Hyrcanus; (2) xxxvii.-lxxi., xvii.-xix., before 64 B.C.; (3) the Noachic fragments, vi. 3-8, viii. 1-3, ix. 7, x. 1, 11, xx., xxxix. 1, 2*, liv. 7-iv. 2, lx., lxx.-lxxix. 25, cvi.-cvii.; and (4) cviii. from a later hand. With much of this analysis there is no reason to disagree. The similitudes are undoubtedly of different authorship from the rest of the book, and certain portions of the book are derived from the *Book of Noah*. On the other hand, the so-called groundwork has no existence unless in the minds of earlier critics and some of their belated followers in the present. It springs from at least four hands, and may be roughly divided into four parts, corresponding to the present actual divisions of the book. Of these we shall deal with the easiest first. *Ch. lxxvii.-lxxxvii.* constitutes a work in itself, the writer of which had very different objects before him from the writers of the rest of the book. His sole aim is to give the law of the heavenly bodies. His work has suffered disarrangements and interpolations at the hands of the editor of the whole work. Thus lxxx. sq. are intrusions, and lxxxii. should stand before lxxix., for the opening words of the latter suppose it to be already read. *Chaps. lxxxviii.-xc.*—This section was written before 161 B.C., for "the great horn," who is Judas the Maccabee, was still warring when the author was writing. (Dillmann, Schürer, and others take the great horn to be John Hyrcanus, but this interpretation does violence to the text.) These chapters recount three visions: the first two deal with the first-world judgment; the third with the entire history of the world till the final judgment. An eternal Messianic kingdom at the close of the judgment is to be established under the Messiah, with its centre in the New Jerusalem set up by God Himself. *Chaps. xci.-civ.*—In the preceding section the Maccabees were the religious champions of the nation and the friends of the Chasids. Here they are leagued with the Sadducees, and are the declared foes of the Pharisaic party. This

section was written therefore after 134 B.C., when the breach between John Hyrcanus and the Pharisees took place and before the savage massacres of the latter by Jannæus in 95 B.C.; for it is not likely that in a book dealing with the sufferings of the Pharisees such a reference would be omitted. These chapters indicate a revolution in the religious hopes of the nation. An eternal Messianic kingdom is no longer anticipated, but only a temporary one, at the close of which the final judgment will ensue. The righteous dead rise not to this kingdom but to spiritual blessedness in heaven itself—to an immortality of the soul. This section also has suffered at the hands of the final editor. Thus xci. 12-17, which describe the last three weeks of the Ten-Weeks Apocalypse, should be read immediately after xciii. 1-10, which recount the first seven weeks of the same apocalypse. But, furthermore, the section obviously begins with xcii. "Written by Enoch the scribe," &c. Then comes xci. 1-10 as a natural sequel. The Ten-Weeks Apocalypse, xciii. 1-10, xci. 12-17, if it came from the same hand, followed, and then xciv. The attempt (by Clemenand Beer) to place the Ten-Weeks Apocalypse before 167, because it makes no reference to the Maccabees, is not successful; for where the history of mankind from Adam to the final judgment is despatched in sixteen verses, such an omission need cause little embarrassment, and still less if the author is the determined foe of the Maccabees, whom he would undoubtedly have stigmatized as apostates, if he had mentioned them at all, just as he similarly brands all the Sadducean priesthood that preceded them to the time of the captivity. This Ten-Weeks Apocalypse, therefore, we take to be the work of the writer of the rest of xci.-civ. *Chaps. i.-xxxvi.*—This is the most difficult section in the book. It is very composite. *Ch. vi.-xi.* is apparently an independent fragment of the Enoch Saga. It is itself compounded of the Semjaza and Azazel myths, and in its present composite form is already presupposed by lxxxviii.-lxxxix. 1; hence its present form is earlier than 166 B.C. It represents a primitive and very sensuous view of the eternal Messianic kingdom on earth, seeing that the righteous beget 1000 children before they die. In the next place xii.-xvi. stand quite apart from the rest of i.-xxxvi. owing to the transcendent picture they give of God as contrasted with what is given in the rest of the section. Likewise they represent what Enoch saw in a dream, whereas xvii.-xxxvi. recount Enoch's actual journeys through the heavens. These chapters were probably an independent fragment of the Enoch Saga. Again, xvii.-xix. stand in a peculiar relation to xx.-xxxvi., since both sections deal with the same subjects. Thus xvii. 4=xxiii.; xvii. 6=xxii.; xviii. 1=xxxiv.-xxxvi.; xviii. 6-9=xxiv.-xxv., xxxii. 1-2; xviii. 11, xix.=xxi. 7-10; xviii. 12-16=xxi. 1-6. They belong to the same cycle of tradition and cannot be independent of each other. *Chap. xx.* appears to show that xx.-xxxvi. is fragmentary, since only four of the seven angels mentioned in xx. have anything to do in xxi.-xxxvi. *Chaps. xxxvii.-lxx.*—These constitute the well-known similitudes. They were written before 64 B.C., for Rome was not yet known to the writer, and after 95 B.C., for the slaying of the righteous, of which the writer complains, was not perpetrated by the Maccabean princes before that date. This section consists of three similitudes—xxxviii.-xliv., xlv.-lvii., lviii.-lxix. These are introduced and concluded by xxxvii. and lxx. There are many interpolations—lx., lxx.-lxxix. 25 come confessedly from the *Book of Noah*; most probably also liv. 7-iv. 2. Whence others, such as xxxix. 1, 2*, xli. 3-8, xliii. sq., spring is doubtful. *Ch. l.*, lvi. 5-lvii. 3* are likewise insertions, and lxxi. an addition, at variance with the thought of the section. The Messianic doctrine and eschatology of this section is unique. The Messiah is here for the first time

described as the pre-existent Son of Man, who possesses universal dominion and is the Judge of all mankind. After the judgment there will be a new heaven and a new earth, which will be the abode of the blessed.

4 *Ezra*.—This apocryph had a very wide circulation among the Greek and Latin fathers. In the Latin version it consists of sixteen chapters, of which, however, only iii.-xiv. are found in the other versions. To iii.-xiv., accordingly, the present notice is confined. After the example of most of the Latin MSS. we designate the book 4 *Ezra* (see Bensly-James, *Fourth Book of Ezra*, pp. xxiv.-xxvii.). In the first Arabic and Ethiopic versions it is called 1 *Ezra*; in some Latin MSS. and in the English Authorized Version it is 2 *Ezra*, and in the Armenian 3 *Ezra*. Chapters i.-ii. are sometimes called 3 *Ezra*, and xv.-xvi. 5 *Ezra*. All the versions go back to a Greek text. This is shown by the late Greek apocalypse of *Ezra* (Tischendorf, *Apocalypses Apocryphæ*, 1866, pp. 24-33), the author of which was acquainted with the Greek of 4 *Ezra*; also by quotations from it in Barn. iv. 4; xii. 1=4 *Ezra* xii. 10 *sqq.* v. 5; Clem. Alex. *Strom.* iii. 16 (here first expressly cited)=4 *Ezra*, v. 35, &c. (see Bensly-James, *op. cit.* pp. xxvii.-xxxviii.). In his *Messias Judæorum*, 1869, pp. 36-110, Hilgenfeld has given a reconstruction of the Greek text. Till 1896 only Ewald believed that 4 *Ezra* was written originally in Greek. In that year Wellhausen (*Gött. Gel. Anz.* pp. 12-13) and Charles (*Apoc. Bar.* p. lxxii.) pointed out that a Hebrew original must be assumed on various grounds; and this view the former established in his *Skizzen u. Vorarbeiten*, vi. 234-240, 1899. Of the numerous grounds for this assumption it will be necessary only to adduce such constructions as “de quo me interrogas de eo,” iv. 28, and xiii. 26 “qui per semet ipsum liberabit” (= אֲשֶׁר-בִּי) = “through whom he will deliver,” or to point to such a mistranslation as vii. 33, “longanimitas congregabitur,” where for “congregabitur” (= אָסַף) we require “evanescet,” which is another and the actual meaning of the Hebrew verb in this passage. The same mistranslation is found in the Vulgate in Hosea iv. 3. This view has been adopted in Gunkel’s German translation of *Ezra* (Kautzsch, *Apok. u. Pseud. d. A. T.* ii. 332-333).

Latin Version.—All the older editions of this version, as those of Fabricius, Sabatier, Volkmar, Hilgenfeld, Fritzsche, as well as in the older editions of the Bible, are based ultimately on only one MS., the Codex Sangermanensis (written A.D. 822), as Gildemeister proved in 1865 from the fact that the large fragment between verses 36 and 37 in chapter vii., which is omitted in all the above editions, originated through the excision of a leaf in this MS. A splendid edition of this version based on MSS. containing the missing fragment, which have been subsequently discovered, has been published by Bensly-James (*op. cit.*). This edition has taken account of all the important MSS. known, save one at Leon in Spain.

Syriac Version.—This version, found in the Ambrosian Library in Milan, was translated into Latin by Ceriani, *Monumenta sacra et profana*, II. ii. pp. 99-124, 1866. Two years later this scholar edited the Syriac text, *op. cit.* V. i. pp. 4-111, and in 1883 reproduced the MS. by photo-lithography (*Translatio Syra Peshitto V. T.* II. iv. pp. 553-572). Hilgenfeld incorporated Ceriani’s Latin translation in his *Messias Judæorum*. This translation needs revision and correction.

Ethiopic Version.—First edited and translated by Laurence, *Primi Ezræ Libri Versio Æthiopia*, 1820. Laurence’s Latin translation was corrected by Prætorius and reprinted in Hilgenfeld’s *Messias Judæorum*. In 1894 Dillmann’s text based on ten MSS. was published—*V. T. Æth. Libri Apocryphi*, v. 153-193.

Arabic Versions.—The first Arabic version was translated from a MS. in the Bodleian Library into English by Ockley (in Whiston’s *Primitive Christianity*, vol. iv. 1711). This was done into Latin and corrected by Steiner for Hilgenfeld’s *Mess. Jud.* The second Arabic version, which is independent of the first, has been edited from a Vatican MS. and translated into Latin by Gildemeister, 1877.

Armenian Version.—First printed in the Armenian Bible, 1805. Translated into Latin by Petermann for Hilgenfeld’s *Mess. Jud.*

Relation of the above Versions.—These versions stand in the

order of worth as follows:—Latin, Syriac, Ethiopic. The remaining versions are paraphrastic and less accurate, and are guilty of additions and omissions. All the versions, save the second Arabic one, go back to the same Greek version. The second Arabic version presupposes a second Greek version.

Modern Versions.—All the English versions are now antiquated, except those in the Variorum Apocrypha and the Revised Version of the Apocrypha, and even these are far from satisfactory. Similarly, all the German versions are behindhand, except the excellent version of Gunkel in *Apok. u. Pseud.* ii. 252-401, which, however, needs occasional correction.

The book (iii.-xiv.) consists of seven visions or parts, like the apocalypse of Baruch. They are: (1) iii. 1-v. 19; (2) v. 20-vi. 34; (3) vi. 35-ix. 25; (4) ix. 26-x. 60; (5) xi. 1-xii. 51; (6) xiii.; (7) xiv. These deal with (1) religious problems and speculations (2) and eschatological questions. The first three are devoted to the discussion of religious problems affecting in the main the individual. The presuppositions underlying these are in many cases the same as those in the Pauline Epistles. The next three visions are principally concerned with eschatological problems which relate to the nation. The seventh vision is a fragment of the *Ezra* Saga recounting the rewriting of the Scriptures, which had been destroyed. This has no organic connexion with what precedes. According to Gunkel (*Apok. u. Pseud.* ii. 335-352) the whole book is the work of one writer. Thus down to vii. 16 he deals with the problem of the origin of suffering in the world, and from vii. 17 to ix. 25 with the question who is worthy to share in the blessedness of the next world. As regards the first problem the writer shows, in the first vision, that suffering and death come from sin—no less truly on the part of Israel than of all men, for God created man to be immortal; that the end is nigh, when wrongs will be righted; God’s rule will then be recognized. In the second he emphasizes the consolation to be found in the coming time, and in the third he speaks solely of the next world, and then addresses himself to the second problem. The fourth, fifth, and sixth visions are eschatological. In these the writer turns aside from the religious problems of the first three visions and concerns himself only with the future national supremacy of Israel. Zion’s glory will certainly be revealed (vision four), Israel will destroy Rome (five) and the hostile Gentiles (six). Then the book is brought to a close with the legend of *Ezra*’s restoration of the lost Old Testament Scriptures.

In the course of the above work there are many inconsistencies and contradictions. These Gunkel explains by admitting that the writer has drawn largely on tradition, both oral and written, for his materials. Thus he concedes that eschatological materials in v. 1-13, vi. 18-28, vii. 26 *sqq.*, also ix. 1 *sqq.*, are from this source, and apparently from an originally independent work, as Kabisch urges, but that it is no longer possible to separate the borrowed elements from the text. Again, in the four last visions he is obliged to make the same concession on a very large scale. Vision four is based on a current novel, which the author has taken up and put into an allegorical form. Visions five and six are drawn from oral or written tradition, and relate only to the political expectations of Israel, and seven is a reproduction of a legend, for the independent existence of which evidence is furnished by the quotations in Bensly-James, pp. xxxvii.-xxxviii. Thus the chief champion of the unity of the book makes so many concessions as to its dependence on previously existing sources that, to the student of eschatology, there is little to choose between his view and that of Kabisch. In fact, if the true meaning of the borrowed materials is to be discovered, the sources must be disentangled. Hence the need of some such analysis as that of Kabisch (*Das vierte Buch Ezra*, 1889): S=an Apocalypse of Salathiel, circ. A.D. 100, preserved in a fragmentary condition, iii. 1-31,

iv. 1-51, v. 13b-vi. 10, 30-vii. 25, vii. 45-viii. 62, ix. 13-x. 57, xii. 40-48, xiv. 28-35. E = an Ezra Apocalypse, circ. 31 B.C., iv. 52-v. 13a, vi. 13-28, vii. 26-44, viii. 63-ix. 12. A = an Eagle Vision, circ. A.D. 90, x. 60-xii. 35. M = a Son-of-Man Vision, xiii. E² = an Ezra fragment, circ. A.D. 100, xiv. 1-17a, 18-27, 36-47. All these, according to Kabisch, were edited by a Zealot, circ. 120, who supplied the connecting links and made many small additions. In the main this analysis is excellent. If we assume that the editor was also the author of S, and that such a vigorous stylist, as he shows himself to be, recast to some extent the materials he borrowed, there remains but slight difference between the views of Kabisch and Gunkel. Neither view, however, is quite satisfactory, and the problem still awaits solution. Other attempts, such as Ewald's (*Gesch. d. Volkes Israel*³, vii. 69-83) and De Faye's (*Apocalypses Juives*, 155-165), make no contribution.

Time and Place.—The work was written towards the close of the 1st century (iii. 1, 29) and somewhere in the east.

Literature.—In addition to the authorities mentioned above, see Dillmann, Herzog's *Real Enzyk.*² xii. 353 *eqq.*; Schürer, *Gesch. des Jüd. Volkes*³, iii. 246 *sqq.*; and the articles on 4 Esdras in Hastings' *Bible Dictionary* and the *Encyclopædia Biblica* by Thackeray and James respectively.

The Assumption of Moses.—This book was lost for many centuries till a large fragment of it was discovered and published by Ceriani in 1861 (*Monumenta Sacra*, I. i. 55-64) from a palimpsest of the 6th century. Very little was known about the contents of this book prior to this discovery. One passage found in this fragment is quoted in the *Acta Synodi Nicænæ*, ii. 18. Most of the other references relate to the strife of Michael and Satan about the body of Moses, and ascribe it the Ascensio Mosis, *i.e.*, 'Ἀνάληψις Μωυσέως. (Various other works have been attributed to Moses, such as the Petirath Moshe, the βιβλος λόγων Μυστικῶν Μωυσέως, The Exodus of Moses (in Slavonic), &c. See Charles, *Assumption of Moses*, pp. xiv.-xvii.; Schürer, *Gesch. des Jüd. Volkes*, iii. 220-221.)

Editions and Translations.—In addition to those mentioned in *Ency. Brit.* ii. 177, the only complete edition has been published by Charles, *The Assumption of Moses*, 1897. A German translation, with notes by Clemen, will be found in Kautzsch's *Apok. und Pseud.* ii. 311-331. That our Latin text is derived from the Greek there can be no question. Thus Greek words are transliterated, as "chedrio" from κεδρώ, "heremus" from ἐρήμος; Greek idioms are reproduced, as "usque nos duci captivos" = ἕως τοῦ ἡμᾶς αἰχμαλωτισθῆναι, and retranslation into Greek is frequently necessary in order to correct the misrenderings of the translator or the corruptions already inherent in the Greek. Finally, fragments of the Greek version are still preserved. That the Greek was in turn derived from a Semitic original was denied by Hilgenfeld, Volkmar, and others. It is still regarded as an open question by Clemen. On the other hand, Ewald, Schmidt-Merx, Colani, Carriere, Hausrath, Dalman, Rosenthal, and others decide in favour of a Semitic. The present writer has sought at some length to prove that the Greek goes back not to an Aramaic original, but to a Hebrew (see *op. cit.* pp. xxxviii.-xlv.).

The present book is possibly the long-lost Διαθήκη Μωυσέως mentioned in some ancient lists; for it never speaks of the assumption of Moses, but always of his natural death (i. 15, iii. 13, x. 14). About a half of the original Testament is preserved in the Latin version. The latter half probably dealt with questions about the Creation. (See Fabric. *Cod. Pseud. V. T.* ii. 844; *Acta Synodi Nicænæ*, ii. 20.) With this "Testament" the "Assumption," to which almost all the patristic references and that of Jude are made, was subsequently edited. The book has been assigned to most periods between the

death of Herod the Great and that of Bar-Cochba. But the text precludes any date after A.D. 70. The true date appears to lie between 4 B.C. and A.D. 30. Herod is already dead (vi. 6), hence it is after 4 B.C.; and Herod's sons are to rule for shorter periods than their father, hence it must have been composed before these princes had reigned thirty-four years—*i.e.*, before A.D. 30. It may also be shown that A.D. 7 is probably the earlier limit (see Charles, *op. cit.* pp. lv.-lviii.). As for the author, he was no Essene, for he recognizes animal sacrifices and cherishes the Messianic hope; he was not a Sadducee, for he looks forward to the establishment of the Messianic kingdom (x.); nor a Zealot, for the quietistic ideal is upheld (ix.) and the kingdom is established by God Himself (x.). He is therefore a Chasid of the ancient type, and glorifies the ideals which were cherished by the old Pharisaic party, but which were now being fast disowned in favour of a more active rôle in the political life of the nation. He pours his most scathing invectives on the Sadducees, who are described in vii. in terms that recall the anti-Sadducean *Psalms of Solomon*. His object, therefore, is to protest against the growing secularization of the Pharisaic party through its adoption of popular Messianic beliefs and political ideals.

See *Ency. Brit.* ii. 177; *Ency. Bibl.* i. 233-236; Burkitt in Hastings' *Bible Dict.* iii. 448-450; Charles, *Assumption of Moses*, 1897; Schürer, *Gesch. d. Jüd. Volkes*³, 1900, pp. 213-222.

Book of Noah.—Though this book has not come down to us independently, it has in large measure been incorporated in the Ethiopic *Book of Enoch*, and can in part be reconstructed from it. The *Book of Noah* is mentioned in Jubilees x. 13, xxi. 10. Ch. lx., lxv.-lxix. 25 of the Ethiopic Enoch are without question derived from it. Thus lx. 1 runs: "In the year 500, in the seventh month . . . in the life of Enoch." Here the editor simply changed the name Noah in the context before him into Enoch, for the statement is based on Gen. v. 32, and Enoch lived only 365 years. Chapters vi.-xi., cvi.-cvii. of the same book are probably from the same source; likewise liv. 7-lv. 2, and Jubilees vii. 26-39, x. 1-15. In the former passage of Jubilees the subject-matter leads to this identification, as well as the fact that Noah is represented as speaking in the first person, although throughout Jubilees it is the angel that speaks. Possibly Eth. En. xli. 3-8, xliii.-xliv., lix., are from the same work. The book may have opened with Eth. En. cvi.-cvii. On these chapters may have followed Eth. En. vi.-xi., lxv.-lxix. 25, lx., xli. 3-8, xliii.-xliv., liv. 7-lv. 2; Jubilees vii. 26-39, x. 1-15. Since some of these chapters are earlier than Eth. En. lxxxiii.-xc. and Jubilees, the original work is not later than 166 B.C. (See Hastings' *Bible Dict.* iii. 586-587.)

The Hebrew *Book of Noah*, a later work, is printed in Jellinek's *Bet ha-Midrash*, iii. 155-156, and translated into German in Rönisch, *Das Buch der Jubiläen*, 385-387. It is based on the part of the above *Book of Noah* which is preserved in Jubilees. The portion of this Hebrew work which is derived from the older work is reprinted in Charles's Ethiopic version of the Hebrew *Book of Jubilees*, p. 179.

Testaments of the XII Patriarchs.—The earliest reference to this book is found in Origen in his *Hom. in Josuam*, xv. 6 (Ed. Lommatzsch, xi. 143): "In aliquo quodam libello qui appellatur testamentum duodecim patriarcharum, quamvis non habeatur in canone, talem tamen quendam sensum invenimus, quod per singulos peccantes singuli Satanæ intelligi debeant" (*cf.* Reuben, iii.). The Testaments are mentioned simply as Πατριάρχαι in the Stichometry of Nicephorus, the Synopsis Athanasii, and the anonymous list of books edited by Montfaucou and others. From this period the Testaments

were lost sight of till the 13th century, when they were translated into Latin from a 10th-century MS. (now in Cambridge) by Grosseteste, bishop of Lincoln. The work consists of the dying commands of the twelve sons of Jacob to their children. Each testament treats of a special virtue or vice which finds illustration in the life of the particular patriarch. Three elements are distinguishable in each testament:—(1) The patriarch in each gives an account of his life, dwelling with particular emphasis on his particular virtues or vices. In many respects these accounts are of the nature of a Midrash on the Biblical notices concerning him, but in some instances they are in sharp conflict with them. (2) After the historical or legendary notices just referred to the patriarch gives appropriate exhortations, naturally suggested by the qualities conspicuous in his own career. (3) Finally he appends a series of predictions.

Grabe (*Spicileg. Patrum*², 1714, i. 129-144, 335-374) was the first to suggest that the work was written by a Jew and subsequently interpolated by a Christian. Most subsequent writers, however, rejected Grabe's view, and so the exegesis of the book became a mere series of fruitless logomachies till Schnapp revived Grabe's hypothesis in an excellent piece of work, *Die Test. der XII Patr. untersucht*, 1894, Halle. This critic has tried to prove, firstly, that in its original form the book consisted of biographical details respecting each of the patriarchs, and exhortations suggested by these details: next, that this work was revised by a Jew, who added the portions of an apocalyptic or predictive nature: and thirdly, that the book thus enlarged was revised by a Christian, who modified some passages and in others introduced interpolations. The third thesis has been confirmed by Conybeare's collation of the Armenian version (*Jewish Quarterly Review*, 1893, 387 sqq.; 1896, 260 sqq., 471 sqq.) which omits most of the Christian passages in the Greek version. But Bousset has overthrown Schnapp's second thesis and shown that the apocalyptic sections belonged to the original work: see "Die Testamente der Zwölf Patriarchen" in the second number of Preuschen's *Zeitschr. f. d. NTliche Wissenschaft*.

Till the last few years it has been generally believed that the Testaments were originally written in Greek. But this appears most improbable, and there are good grounds for supposing a Semitic original. In the first place, the greater part of the work cannot be later than 100 B.C. In the next the Greek is thoroughly Semitic in character. Gaster has published a Hebrew text of the *Testament of Naphtali*, which he holds to be the original of the Greek. That this is not so, the present writer has shown in *Ency. Biblica*, i. 239-240. Gaster's text, which is a late compilation possessing some materials in common with the Greek, is nevertheless of service in explaining through the Hebrew how one hopelessly corrupt passage in the Greek arose. Furthermore, in favour of a Hebrew original, it may be urged that—(1) Hebrew constructions are frequent; (2) paronomasiæ, which are lost in the Greek but can be restored by re-translation, are frequent; and (3) certain passages which are unintelligible in the Greek become clear on re-translation. On the other hand, see Pass and Arenden's "Fragment of an Aramaic Text of the Testament of Levi" in *Jewish Quarterly Review*, 1900, pp. 651-661.

Versions.—The Greek version was edited by Sinker from two MSS. in 1869 and the variants of two other MSS. in an appendix in 1879. This scholar has long promised a new edition from six MSS., and another is said to be in preparation by von Gebhardt. There were also early Syriac and Armenian versions. Of the former only a small fragment survives. The latter was published at Venice in 1896. Most of its variants have been made accessible through Conybeare in the *Jewish Quarterly Review* above referred

to, and through "Preuschen's Die armenische Uebersetzung der Testamente der zwölf Patriarchen" in the second number of Preuschen's *Z. f. d. NTliche Wissensch. u. d. Kunde d. Urchristenthums*, 1900.

Date.—Excluding the Christian additions, which were made at different dates down to the 5th century, the work was composed towards the close of the 2nd century B.C., with the exception of Levi x. xiv.-xvi., Judah xxii.-xxv., and certain fragments in Dan. v. and Zebulon ix., which belong to the 1st century B.C. See Bousset in Preuschen's review (mentioned above), 1900, pp. 142-175, 187-209, and the articles by Charles, *in loc.*, in *Ency. Biblica*, i. 237-241, and Hastings' *Bible Dictionary*, iv.

Psalms of Solomon.—These psalms, in all eighteen, enjoyed but small consideration in early times, for only six direct references to them are found in early literature. Their ascription to Solomon is due solely to his scribes, for no such claim is made in any of the psalms.

There are only three valuable editions of the text:—Ryle and James, *Ψαλμοὶ Σολομῶντος, The Psalms of the Pharisees*, 1891, from five MSS.; Swete, *The Old Testament in Greek*, iii. 1894, 765-787, from six MSS.; Gebhardt, *Ψαλμοὶ Σολομῶντος—Die Psalmen Salomons zum ersten Male mit Benutzung d. Athoshandschriften und d. Cod. Casanatensis*, 1895, from five MSS., three of which are used for the first time. The best recent translation into English is that of Ryle and James. It has been done into German by Wellhausen in the appendix to his *Die Phariseer u. Sadducäer*, 1874, and recently by Kittel in Kautzsch's *Apok. u. Pseud. des A. T.* ii. 130-148. The latter translation is based on Gebhardt's text.

The second psalm was written soon after 48 B.C., for it contains a triumphant reference to Pompey's death, ii. 29-31. Pss. i., viii., and xvii. fall between 63 and 48 B.C., for they presuppose Pompey's capture of Jerusalem, but show no knowledge of his death. Pss. v., vii., ix., xiii., xv., belong apparently to the same period, but iv. and xii. to an earlier one. On the whole Ryle and James are no doubt right in assigning 70-40 B.C. as the limits within which the psalms were written. The authors were Pharisees. They divide their countrymen into two classes—"the righteous," ii. 38-39, iii. 3-5, 7, 8, &c., and "the sinners," ii. 38, iii. 13, iv. 9, &c.; "the saints," iii. 10, &c., and "the transgressors," iv. 11, &c. The former are the Pharisees; the latter the Sadducees. They protest against the Asmonæan house for usurping the throne of David and laying violent hands on the high priesthood, xvii. 5, 6, 8, and proclaim the coming of the Messiah, the Son of David, who is to set all things right and establish the supremacy of Israel. Pss. xvii.-xviii. and i.-xvi. cannot be assigned to the same authorship. The hopes of the Messiah are confined to the former, and a somewhat different eschatology underlies the two works (see Charles, *Eschatology: Hebrew, Jewish, and Christian*, 220-225). There can be no doubt that Hebrew was the original language. This would follow from the fact that they were sung in the public worship of the synagogue, as we infer from the inscriptions. But independently of this fact it is impossible to translate the Greek intelligibly, save on this hypothesis: see the excellent commentary of Ryle and James, pp. lxxvii.-lxxxvii. Since the Psalms were written in Hebrew, and intended for public worship in the synagogues, it is most probable that they were composed in Palestine. Besides, not a shred of evidence can be adduced in favour of any other country.

In addition to the literature mentioned above and in Ryle and James's edition, Schürer's *Gesch. des Jüd. Volkes*³, iii. 150 sqq., see *Ency. Biblica*, i. 241-245.

Lost Apocalypses: Prayer of Joseph.—The *Prayer of Joseph* is quoted by Origen [*In Joann.* II. xxv. (Lommatsch, i. 147, 148); *in Gen.* III. ix. (Lommatsch, viii. 30-31)]. The fragments in Origen represent Jacob as speaking and claiming to be "the first servant in God's presence," "the first-begotten of every creature animated by God," and declaring that the angel who wrestled with Jacob (and was identified by Christians with Christ) was

only eighth in rank. The work was obviously anti-Christian. (See Schürer³, iii. 265-266.)

Book of Eldad and Modad.—This book was written in the name of the two prophets mentioned in Num. xi. 26-29. It consisted, according to the Targ. Jon. on Num. xi. 26-29, mainly of prophecies on Magog's last attack on Israel. The Shepherd of Hermas quotes it *Vis.* ii. 3. (See Marshall in Hastings' *Bible Dictionary*, i. 677.)

Apocalypse of Elijah.—This apocalypse is mentioned in two of the lists of books. Origen, Ambrosiaster, and Euthalius ascribe to it 1 Cor. ii. 9. If they are right, the apocalypse is pre-Pauline. The peculiar form in which 1 Cor. ii. 9 appears in Clemens Alex. *Protrept.* x. 94, and the *Const. Apost.* vii. 32 shows that both have the same source, probably this apocalypse. Epiphanius (*Hær.* xlii. ed. Oehler, vol. ii. 678) ascribes to this work Eph. v. 14. Isr. Lévi (*Revue des Études Juives*, 1880, i. 108 sqq.) argues for the existence of a Hebrew apocalypse of Elijah from two Talmudic passages. A late work of this name has been published by Jellinek, *Bet ha-Midrash*, 1855, iii. 65-68 and Buttenwieser in 1897. Zahn, *Gesch. des NTKanons*, ii. 801-810, assigns this apocalypse to the 2nd century A.D. (See Schürer³, iii. 267-271.)

Apocalypse of Zephaniah.—Apart from two of the lists this work is known to us in its original form only through a citation in Clem. Alex. *Strom.* v. 11, 77. A Christian revision of it is probably preserved in the two dialects of Coptic. Of these the Achmim text is the original of the Sahidic. These texts and their translations have been edited by Steindorff, *Die Apokalypse des Elias, eine unbekannte Apokalypse und Bruchstücke der Sophonias-Apokalypse*, 1899. As Schürer (*Theol. Literaturzeitung*, 1899, No. I. 4-8) has shown, these fragments belong most probably to the Zephaniah apocalypse. They give descriptions of heaven and hell, and predictions of the Antichrist. In their present form these Christianized fragments are not earlier than the 3rd century. (See Schürer, *Gesch. des Jüd. Volkes*³, iii. 271-273.)

(iv.) Wisdom Literature.

The Pirke Aboth.—These sayings of the Jewish fathers are preserved in the 9th Tractate of the Fourth Order of the Mishna. They are attributed to some sixty Jewish teachers, and the collection is divided into five chapters. These teachers belong for the most part to the years A.D. 70-170, though a few of them are of a much earlier date. (See P. Ewald's *Pirke Aboth*, 1825; Strack, *Die Sprüche der Väter*², 1888; Taylor, *Sayings of the Jewish Fathers*², 1899.)

Sirach or Ecclesiasticus.—This book bore the name "Proverbs" (כְּתוּבֵי הַמִּשְׁלֵי), according to Jerome. It was also known as "The Wisdom of Jesus, the son of Sirach" (Σοφία Ἰησοῦ υἱοῦ Σεράχ, or, more shortly, Σοφία Σεράχ). In the Latin Church the book was, so far as we know, first called *Ecclesiasticus* in Cyprian (*Testim.* ii. 1; iii. 1, &c.). The expression "Libri ecclesiastici" in Church writers designates the apocryphal books of the Old Testament in contradistinction from the canonical books. Among such books *Ecclesiasticus* was the Church book, κατ' ἐξοχὴν. The name of the author is given in the Greek of l. 27 as "Jesus, the son of Sirach," but in the Hebrew of l. 27 and li. 30 as "Simon, son of Joshua, son of Eleazar, son of Sira."

The prologue states that the Sirach's grandson went to Egypt in the 38th year of Euergetes. Since of the two Ptolemies who bore the surname of Euergetes, the first reigned only twenty-five years, it must be the second that is referred to here, i.e., Ptolemy VII. Physcon Euergetes II. This prince began to reign in 170 B.C.

Hence 132 is the date of the arrival of Sirach's grandson in Egypt, and the composition of Sirach's work would be from forty to seventy years earlier. Thus the date would lie between 200 and 170 B.C. This date would harmonize well with the apparently contemporary account of the High-priest Simon II. in l. 1-26, who was in office about 200 B.C. Edersheim (*Speaker's Apocrypha*, ii. 4-9) and others contest this view. See, however, Ryssel (Kautzsch's *Apok. u. Pseud.* i. 234-239; *Ency. Biblica*, ii. 1170-1171). That this book was written in Hebrew is stated by Jerome; but, with the exception of occasional sentences in the Talmud, it was lost to modern scholarship till 1896, when chaps. xxxix. 15-xlix. 11 were published by Cowley and Neubauer. This large fragment of the original text was found in a synagogue in Cairo. The discovery and publication of further fragments have followed in fast succession. In 1899 Schechter and Taylor edited chaps. iii. 6-vii. 29; xi. 34; xii. 2-xvi. 26; xxx. 11-xxxii. 11; xxxiii. 1-xxxiii. 3; xxxv. 9-20; xxxvi. 1-21; xxxvii. 27-xxxviii. 27; xlix. 12-li. 30. In the same year G. Margoliouth published in the *Jewish Quarterly Review* chaps. xxxi. 12-31; xxxvi. 22-xxxvii. 26; and on pp. 462-465 of the same review in 1900 appeared further fragments discovered by Schechter, i.e., iv. 23b, 30-31; v. 4-7, 9-13; xxv. 8b, 13, 17-24; xxvi. 1-2a; xxxvi. 19a; and on pp. 466-480 fragments discovered by Adler, vii. 29-xi. 33; xii. 1; and on pp. 688-702 fragments discovered by Gaster, xviii. 31-xix. 2; xx. 5-7; xxxvii. 19, 22, 24, 26; xx. 13; and finally in the *Revue des Études Juives*, 1900, pp. 1-30, the fragments discovered by Lévi—xxxvi. 24-26; xxxvii. 1-xxxviii. 1. Margoliouth's theory that these fragments are not part of the original Hebrew text, but of a mediæval Hebrew version, is rejected almost universally, both by Jewish and Christian scholars.

Versions—Greek and Syriac.—These versions are from the Hebrew. The Greek is preserved in * A B C and Cod. Ven. of the Uncials, and in a large number of cursives. All these MSS. go back to the same Greek text, for they all attest the remarkable transposition in xxx.-xxxvi. The right order is preserved in the Syriac, Latin, and Arabic versions. We should, therefore, place xxx. 25-xxxiii. 13a after xxxiii. 13b-xxxvi. 16a. The right order appears, it is true, in Cursive 248, but the form of the text shows that the dislocation existed in the text from which it was derived, and was set right subsequently. The Greek and Syriac are invaluable in the criticism of the Hebrew fragments.

Latin and Other Versions.—The Latin version, which preserves the right order in xxx.-xxxvi., and is herein followed by the English version, was made from the Greek before these chapters were dislocated. This version dates from A.D. 200-250. It occasionally preserves the right text where the Greek has since become corrupt. The Syro-Hexaplaric, Ethiopic, Armenian, and Coptic versions were derived from the Greek after the transposition of chaps. xxx.-xxxvi.

Literature.—Owing to the recent discoveries and innumerable studies on the Hebrew texts and the various versions, all the earlier works are to a great degree antiquated. The best are Fritzsche's *Die Weisheit Jesus-Sirachs*, 1859, and Edersheim's commentary in the *Speaker's Apocrypha*, ii. 1-239. In the latter work and Schürer's *Gesch. des Jüd. Volkes*³, iii. 161-166, a full bibliography will be found. See particularly Toy in *Ency. Bib.* ii. 1164-1179. Smend has promised a comprehensive edition, taking into account all the most recent discovery and criticism.

II.—HELLENISTIC LITERATURE.

(i.) Historical and Legendary.

Additions to Daniel.—These are three in number: *Susannah and the Elders*, *Bel and the Dragon*, and *The Song of the Three Children*. Of these the two former have no organic connexion with the text. The case is otherwise with regard to the last. In some respects it helps to fill up a gap in the canonical text between verses 23 and 24 of chapter iii. And yet we find Polychronius, early in the 5th century, stating that this song was not found in the Syriac version.

Song of the Three Children.—This section is composed of the Prayer of Azariah and the Song of Azariah, Ananias, and Misael, and was inserted after iii. 23 of the canonical text of Daniel. According to Fritzsche, König, Schürer, &c., it was composed in Greek and added to the Greek translation. On the other hand, Delitzsch, Bissell, Ball, &c., maintain a Hebrew original. The latter view has been recently supported by Rothstein, *Apok. und Pseud.* i. 173-176, who holds that these additions were made to the text before its translation in Greek. These additions still preserve, according to Rothstein, a fragment of the original text, i. e., verses 23-28, which came between verses 23 and 24 of chapter iii. of the canonical text. They certainly fill up excellently a manifest gap in this text. "The Song of the Three Children" was first added after the verses just referred to, and subsequently the Prayer of Azariah was inserted before these verses.

Susannah.—This addition was placed by Theodotion before chap. i., and "Bel and the Dragon" at its close, whereas by the LXX. and the Vulgate it was reckoned as chap. xiii. after the twelve canonical chapters, Bel and the Dragon as xiv. Theodotion's version is the source of the Peshitto for all three additions, and the LXX. is the source of the Syro-Hexaplaric, which has been published by Ceriani (*Mon. Sacr.* vii.). The source of the story may, according to Ewald (*Gesch.* iv. 636), have been suggested by the Babylonian legend of the seduction of two old men by the goddess of love. Daniel appears in this addition as a youthful judge. Notwithstanding the paronomasiae on Greek words in verses 54-55, 58-59, to which attention was called by Julius Africanus and Porphyry, it is by no means certain that the original was Greek. We may have here a free rendering of a Semitic original (see Bludau, *Die Alexandrinische Uebersetzung des Buches Daniel*, 1897).

Bel and the Dragon.—We have here two independent narratives, in both of which Daniel appears as the destroyer of heathenism. The latter had a much wider circulation than the former, and is most probably a Judaized form of the old Semitic myth of the destruction of the old dragon, which represents primeval chaos (see Ball, *Speaker's Apocr.* ii. 346-348; Gunkel, *Schöpfung und Chaos*, 320-323). Most scholars maintain a Greek original, but this is by no means certain. Marshall (*Hastings' Bible Dict.* i. 268) argues for an Aramaic, and regards Gaster's Aramaic text (*Proceedings of the Society of Biblical Archaeology*, 1894, pp. 280-290, 312-317; 1895, 75-94) as of primary value in this respect.

Additions to Esther.—These seven additions, written originally in Greek, were interpolated in the Greek translation of the *Book of Esther*. They consist of an edict of Haman, prayers of Mordecai and Esther, &c., and are so skilfully interpolated as to make no interruption in the history, though they occasionally contradict the canonical text. The Greek text appears in two widely-differing recensions. The one is supported by A B α , and the other—a revision of the first—by codices 19, 93^a, 108^b. The latter is believed to have been the work of Lucian. For an account of the Latin and Syriac versions, the Targums, and the later Rabbinic literature connected with this subject, and other questions relating to these additions, see Fritzsche, *Exeget. Handbuch zu den Apok.* 1851, i. 67-108; Schürer³, iii. 330-332; Fuller in *Speaker's Apocr.* i. 360-402; Ryssel, Kautzsch, *Apok. u. Pseud.* i. 193-212.

Epistle of Jeremy.—This letter (see *Ency. Brit.* iii. 405-406) purports to have been written by Jeremiah to the exiles who were already in Babylon or on the way thither. Recent research has not done much to elucidate the difficulties of this writing (see Fritzsche, *Handb. zu den Apok.* 1851; Gifford, *Speaker's Apocr.* ii. 286-303; Marshall, *Hastings' Bible Dict.* ii. 578-579).

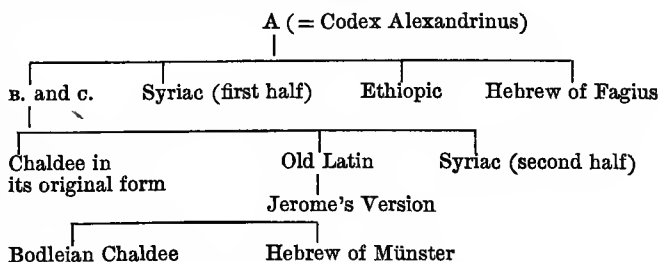

2 Maccabees.—This book (see *Ency. Brit.* xv. 131) was written in the Pharisaic interest, probably by an Alexandrian Jew, although his work shows no trace of distinctively Alexandrian Judaism. Its aim is religious rather than historical, and where it comes into collision with 1 Macc. its evidence is generally set aside as worthless. On the other hand, it has undoubtedly a value of its own; and at times, in accord with Josephus, who was unacquainted with it (*cf.* iv. ; vi. 2; xiii. 3-8; xiv. 1; see Grimm, *Exeget. Handbuch*, 1857, p. 13), it furnishes us, where 1 Macc. is silent, with historical materials of great worth. Geiger held that it was written as a deliberate

polemic against 1 Macc., and Kusters (*Theol. Tijdschrift*, 1878, pp. 491-558) further argued that the so-called epitomizer was the actual author, and merely assumed the mask of Jason's name for controversial purposes. Although Kamphausen (*Apok. und Pseud.* i. 84) follows Kusters' lead, this view is preposterous. That a writer who wished to advocate the doctrines of Pharisaism should seek authentication by appealing to the work of an African Jew, unless such a work were actually in existence, would be without parallel in pseudepigraphic literature. Moreover, the eschatological details which appear in its narrative are just such as fit in with the eschatological systems of the 2nd century B.C., and were certainly not the current views when the epitomizer wrote between 50 B.C. and A.D. 1.

3 Maccabees.—This so-called book of Maccabees (see *Ency. Brit.* xv. 131) is a piece of fiction, recording an attempted massacre of the Jews under Ptolemy IV. Philopator, and based in part on an old legend preserved in Josephus, *Contra Apion*, ii. 5. The date is quite uncertain—sometime between 100 B.C. and A.D. 70 (see Grimm's *Exeget. Handbuch zu den Apok.* 1853, vol. iii.; Bissell, *Apocrypha*, 1880, pp. 615-637; Kautzsch's *Apok. u. Pseud.* 1900, i. 119-135; Fairweather in *Hastings' Bible Dict.* iii. 192-194).

Prayer of Manasseh.—Scholars are not yet agreed as to the original language of this penitential psalm. Most take it to have been written in Greek, and with these Fritzsche, Schürer, and Ryssel (Kautzsch, *Apok. u. Pseud.* i. 165-168) agree. On the other hand, Fürst, Ewald, Ball, and Budde argue for a Hebrew original. From the statements in 2 Chron. xxxiii. 12, 13, 18, 19, it follows that the chronicler found this prayer in Hebrew in his sources, *The History of the Kings of Israel* and *The History of the Seers*. Ewald regards the Greek as an actual translation of the lost Hebrew, but Ball more wisely takes it as a free rendering of a lost Haggadic narrative founded on the older document from which the chronicler drew his information. This view he supports by showing that there was once a considerable literature in circulation regarding Manasseh's later history. Fritzsche, Ball, and Ryssel agree in assigning this psalm to the Maccabean period. Its eschatology and doctrine "of divine forgiveness" may point to an earlier date. The best short account of the book is given by Ball (*Speaker's Apocrypha*, ii. 361-371); see also Porter in *Hastings' Bible Dictionary*, iii. 232-233.

Tobit.—To the excellent account of this book in *Ency. Brit.* xxiii. 427-428, it will not be necessary to make any great addition. Notwithstanding the arguments of Grätz (*Monatsschr. f. Gesch. des Judenthums*, 1879, pp. 145 sqq., 385 sqq., 433 sqq., 509 sqq.), and of Rosenthal (*Vier apokryphische Bücher*, 1885, pp. 104-150), and of Fuller (*Wace's Apocrypha*, i. 1888, pp. 164-171) for a Hebrew original, the original language is generally, with Nöldeke (*Monatsberichte d. Berliner Akad.* 1879, 45 sqq.), taken to be Greek. The following table constructed by the last-named scholar will explain most briefly the relations of the many versions of this book:

The Hebrew texts published by Gaster, *Proceedings of*

the *Society of Bibl. Archaeology*, 1896, pp. 208-222, 259-271; 1897, pp. 27-38, have no more claim to represent the original than those above referred to.

Place and Date.—The book was most probably written in Egypt subsequently to the Maccabean rising and before the building of the Herodian temple 25 B.C.

On the literary connexion with the story of Achikar, see art. "Achiacharus" in *Ency. Bibl.*

(ii.) *Apocalyptic Literature.*

Slavonic Book of Enoch; or, the Book of the Secrets of Enoch.—This new fragment of the Enochic literature has only recently come to light through five MSS. discovered in Russia and Servia. Since about A.D. 500 it has been lost sight of. It is cited without acknowledgment in the *Book of Adam and Eve*, the *Apocalypses of Moses and Paul*, the *Sibylline Oracles*, the *Ascension of Isaiah*, the *Epistle of Barnabas*, and referred to by Origen and Irenæus (see Charles, *The Book of the Secrets of Enoch*, 1895, pp. xvii.-xxiv.). For Charles's *editio princeps* of this work, in 1895, Professor Morfill translated two of the best MSS., as well as Sokolov's text, which is founded on these and other MSS. In 1896 Bonwetsch issued his *Das slavische Henochbuch*, in which a German translation of the above two MSS. is given side by side, preceded by a short introduction. The main part of the book was written in Greek. This follows from the fact that in xxx. 13 it is said that Adam's name is derived from the four quarters of the earth: that is, from the initial letters of ἀνατολή, δύσις, ἄρκτος, μεσημβρία. This derivation is impossible in Semitic. Portions of the book, however, go back to a Semitic original, seeing that it is quoted in the *Test. XII. Patriarchs*, which was written in Semitic and belongs to the 2nd and 1st centuries B.C. The book in its present form was written in Egypt, for many of its speculations are characteristic of Philo and other Hellenistic writers: its account of the creation, xxv. sq., betrays Egyptian elements, as well as its description of such creations as the Phoenixes and Chalkydries. Since this book quotes Ecclesiasticus, the Ethiopic Book of Enoch, and Wisdom (?), the *terminus a quo* cannot be earlier than 30 B.C., and the *terminus ad quem* must be assumed as earlier than A.D. 70, for the temple is still standing. The author was an orthodox Hellenistic Jew, who lived in Egypt. Thus he believed in sacrifices, xlii. 6, lix. 1, lxvi. 2; in the law, lii. 9, 10; and in an immortality of the blessed, in which the righteous should be clothed in "the raiment of God's glory," xxii. 8. The writer is an eclectic. Platonic (xxx. 16), Egyptian (xxv. 2), and Zend (lviii. 4-6) elements are incorporated in his system.

Oracles of Hystaspes.—See under N. T. Apocalypses.

Testament of Job.—This book was first printed from one MS. by Mai, *Script. Vet. Nov. Coll.* 1833, vii. i. 180, and translated into French in Migne's *Dict. des Apocryphes*, ii. 403. An excellent edition from two MSS. is given by M. R. James, *Apocrypha Anecdota*, ii. pp. lxxii.-cii. 104-137, who holds that the book in its present form was written by a Christian Jew in Egypt on the basis of a Hebrew Midrash on Job in the 2nd or 3rd century A.D. It is a cleverly-written work, but not of much value.

Testaments of the III Patriarchs.—For an account of these three Testaments (referred to in the *Apost. Const.* vi. 16), the first of which only is preserved in the Greek and is assigned by James to the 2nd century A.D., see that scholar's "Testament of Abraham," *Texts and Studies*, ii. 2, 1892, which appears in two recensions from six and three MSS. respectively, and Vassiliev's *Anecdota Græco-Byzantina*, 1893, pp. 292-308, from one MS. already used by James. This work was written in Egypt, according to James, and survives also in Slavonic, Roumanian, Ethiopic,

and Arabic versions. It deals with Abraham's reluctance to die and the means by which his death was brought about. James holds that this book is referred to by Origen (*Hom. in Luc.* xxxv.), but this is denied by Schürer, who also questions its Jewish origin. With the exception of chaps. x.-xi., it is really a legend and not an apocalypse. An English translation of James's texts will be found in the *Ante-Nicene Christian Library*, Clark, 1897, pp. 185-201. The Testaments of Isaac and Jacob are still preserved in Arabic and Ethiopic (see James, *op. cit.* 140-161).

Sibylline Oracles.—We must here content ourselves in the main with referring the reader to *Ency. Brit.* ii. 177-179, xxii. 13-14, for the treatment of this subject. Not much has been done for the exegesis of this book of recent years. The most important contributions are those of Zahn, "Ueber Ursprung und religiösen Charakter der Sibyllinischen Bücher, iv.; v.; viii. 1-216; xii.; xiii." in the *Zeitschrift für kirchl. Wissensch. und kirchl. Leben*, 1886, pp. 32-45, 77-87; Hirsch, *Jewish Quarterly Review*, 1890, pp. 406-429; Deane, *Pseudepigrapha*, 1891, pp. 276-344; Harnack, *Gesch. der altchristl. Litteratur*, i. 762, 861-863; ii. 1, 581-589; Charles, *Ency. Biblica*, i. 245-250; Schürer³, iii. 421-450; Blass in Kautzsch's *Apok. u. Pseud.* ii. 177-184. The best edition of the text is that of Rzach, *Oracula Sibyllina*, 1891. A Latin translation is appended to Alexandre's edition of the text and a German to that of Friedlieb. A translation in English blank verse has been made by Terry, *The Sibylline Oracles*, 1899. A literal prose rendering, with some exegetical notes and a critical introduction, is a desideratum.

(iii.) *Wisdom Literature.*

4 *Maccabees.*—This book (see *Ency. Brit.* xv. 131) bears a distinctly philosophic character. It has the form of a sermon of the synagogue; for, as Freudenthal points out, it presumes the presence of an audience (i. 1, xviii. 1). On the other hand, it was undoubtedly composed with a view to publication in Jewish circles (xviii. 1), for its abstruse style is unfitted for an ordinary congregation. The author is a Hellenistic Jew, but his conception of Judaism is strongly influenced by Stoicism. He teaches that the true Stoic ideal is possible only in Judaism: the passions are to be mastered, not exterminated, by reason; that is, by pious reason. Besides the Hellenistic view that only the soul can attain to a blessed immortality (xiii. 16, xv. 2, xvii. 18) this writer teaches that the martyrdom of the righteous atones for the sin of the people (vi. 29, xvii. 21). Eusebius's ascription of the book to Josephus (*H. E.* III. x. 6) is certainly wrong. The more recent literature on this book comprises Bensly's edition of the Syriac version of this book, *The Fourth Book of Maccabees . . . in Syriac, first edited . . . by the late R. L. Bensly, with an introduction and translations by Barnes*, 1895; Swete's *Old Testament in Greek*, 1894, iii. 729 sqq. Swete gives the text of A and variants from \aleph , the Cod. Ven., and certain fragments of Tischendorf. A German translation based on the above materials will be found in Kautzsch, *Apok. u. Pseud.* ii. 152-177.

5 *Maccabees.*—See *Ency. Brit.* xv. 131.

Wisdom of Solomon.—This pseudepigraph claims to have been written by King Solomon (vii.-ix., cf. ix. 7-8). The writer shows a close acquaintance with the canonical books bearing the name of Solomon. Siegfried (Kautzsch, *Apok. u. Pseud.* i. 476) is of opinion that this work is a deliberate polemic against the Epicurean-minded author of Ecclesiastes, and seeks to present Solomon as an example of Jewish piety. The book was written in Greek by an Alexandrian Jew. Though the Greek has many

Hebraisms (see Grimm, *Buch der Weisheit*, 1860, p. 5; Farrar, *Speaker's Apocrypha*, i. 404) the author displays a remarkable mastery in his use of it. Margoliouth has sought to show that it was composed not in Greek but in later Hebrew (*Journal of the Royal Asiatic Society*, 1890, pp. 263-297). But the strongly idiomatic character of its language, the philosophic cast of the thought, its Hellenistic theology and eschatology (Charles, *Eschatology: Hebrew, Jewish, and Christian*, 1899, pp. 251-258) prove incontestably its original composition in Greek (see Freudenthal's review of Margoliouth in the *Jewish Quarterly Review*, 1891, pp. 722-753). The author was a Jew well versed in Greek literature. Occasionally, it is true, he uses words in a non-Greek sense; but on the other hand he is so thoroughly at home in Greek that, like Philo, he ventures to coin new compound words and phrases. Furthermore, he was a student of Greek philosophy, especially of Plato and the Stoics, and uses familiarly the technical language of the schools (Grimm, *op. cit.* pp. 19-20; Farrar, *op. cit.* i. 407). The references to Egyptian animal-worship in xv. 18, 19, xvi. 1, 9, and the Hellenistic type of eschatology point to Egypt as the home of the author. The book is later than *Ecclesiasticus*, and probably earlier than Philo's writings. Hence in all likelihood it originated at some time within the years 150 B.C. and A.D. 10. The writer's object is to warn men against the folly of ungodliness, and particularly of idolatry. He takes his stand on the current dogmas of Platonic philosophy as to the essentially evil nature of matter and the pre-existence of the soul. Hence he teaches not the resurrection of the body but the immortality of the soul. This consummation can be attained only through the life of wisdom.

Texts, Versions, and Editions.—In *The Old Testament in Greek*, ii., Swete follows B, and gives in the notes the variants of A, A and C. Fritzsche, in his *Libri Apocryphi V. T. Græce*, 1871, gives, in addition to the documents of the above MSS., those of Cod. Ven., the cursives and the versions; but his collation of B is untrustworthy. In *The Book of Wisdom*, 1881, Deane gives the Greek text (agreeing mostly with Fritzsche), the Latin version, and an English translation and commentary. Besides the Latin there are Syriac, Ethiopic, Armenian, and Arabic versions. Of these the Armenian is said to be the most faithful. For literature generally, see Schürer², iii. 382-383.

I.—*Gospels.*

Gospel according to the Egyptians.—This gospel is first mentioned by Clem. Alex. (*Strom.* iii. 63, 93), subsequently by Origen (*Hom. in Luc.* i.) and Epiphanius (*Hær.* lxii. 2), and a fragment is preserved in the so-called epistle of Clem. Rom. xii. It circulated among various heretical circles: amongst the Encratites (Clem. *Strom.*

iii. 9), the Naassenes (Ps. Orig. *Philos.* v. 7), and the Sabellians (Epiph. *Hær.* lxii. 2). Only three or four fragments survive; see Lipsius (Smith and Wace, *Dict. of Christ. Biog.* ii. 712, 713); Zahn, *Gesch. d. NTlichen Kanons*, ii. 628-642; Preuschen, *Reste d. ausserkanonischen Evangelien*, 1901, p. 2, which show that it was a product of pantheistic Gnosticism. Lipsius and Zahn assign it to the middle of the 2nd century.

Fayum Gospel Fragment.—This small fragment contains two sayings of Christ and one of Peter, such as we find in the canonical gospels, Mt. xxvi. 31-34, Mk. xiv. 27-30. The papyrus, which is of the 3rd century, was discovered by Bickell among the Raines collection, who characterized it (*Z. f. kath. Theol.* 1885, pp. 498-504) as a fragment of one of the primitive gospels mentioned in Luke i. 1. On the other hand, it has been contended that it is merely a fragment of an early patristic homily. (See Zahn, *op. cit.* ii. 780-790; Harnack, *Texte und Untersuchungen*, v. 4; Preuschen, *op. cit.* p. 19.)

Gospel according to the Hebrews.—This gospel was cited by Ignatius (*Ad Smyrncæos*, iii.) according to Jerome (*Viris illus.* 16, and *in Jes.* lib. xviii.), but this is declared to be untrustworthy by Zahn, *op. cit.* i. 921; ii. 701, 702. It was written in Aramaic in Hebrew letters, according to Jerome (*Adv. Pelag.* iii. 2), and translated by him into Greek and Latin. Both these translations are lost. A collection of the Greek and Latin fragments that have survived, mainly in Origen and Jerome, will be found in Hilgenfeld's *NT extra Canonem receptum*, Nicholson's *Gospel according to the Hebrews* (1879), Westcott's *Introd. to the Gospels*, and Zahn's *Gesch. des NTlichen Kanons*, ii. 642-723; Preuschen, *op. cit.* 5-11. This gospel was regarded by many in the first centuries as the Hebrew original of the canonical Matthew (Jerome, *in Matt.* xii. 13; *Adv. Pelag.* iii. 1). With the canonical gospel it agrees in some of its sayings; in others it is independent. It circulated among the Nazarenes in Syria, and was composed, according to Zahn (*op. cit.* ii. 722), between the years 135 and 150. Jerome identifies it with the *Gospel of the Twelve* (*Adv. Pelag.* iii. 2), and states that it was used by the Ebionites (*Comm. in Matt.* xii. 13). Zahn (*op. cit.* ii. 662, 724) contests both these statements. The former he traces to a mistaken interpretation of Origen (*Hom. I. in Luc.*). Lipsius, on the other hand, accepts the statements of Jerome (Smith and Wace, *Dict. of Christian Biography*, ii. 709-712), and is of opinion that this gospel in the form in which it was known to Epiphanius, Jerome, and Origen, was "a recast of an older original," which, written originally in Aramaic, was nearly related to the Logia used by St Matthew and the Ebionitic writing used by St Luke, "which itself was only a later redaction of the Logia."

Protevangel of James.—This title was first given in the 16th century to a writing which is referred to as *The Book of James* (ἡ Βίβλος Ἰακώβου) by Origen (tom. xi. *in Matt.*). The narrative extends from the Conception of the Virgin to the Death of Zacharias. Lipsius shows that in the present form of the book there is side by side a strange "admixture of intimate knowledge and gross ignorance of Jewish thought and custom," and that accordingly we must "distinguish between an original Jewish Christian writing and a Gnostic recast of it." The former was known to Justin (*Dial.* 78, 101) and Clem. Alex. (*Strom.* vii. 16), and belongs at latest to the earliest years of the 2nd century. The Gnostic recast Lipsius dates about the middle of the 3rd century. From these two works arose independently the *Protevangel* in its present form and the Latin pseudo-Matthæus. The *Evangelium de Nativitate Mariæ* is a redaction of the latter. (See Lipsius in Smith's *Dict. of Christ. Biog.* ii. 701-703.) Zahn (*Gesch. Kanons*, i. 485, 499, 502, 504, 539; ii. 774-780) assigns the *Protevangel* to the first decade of the 2nd century.

¹ Only such works as were written or are supposed to have been written before A.D. 170 will be considered here.

The Logia (q.v.).—This name is given to the sayings contained in a papyrus leaf by its discoverers Grenfell and Hunt. They think the papyrus was probably written about A.D. 200. According to Harnack, it is an extract from the *Gospel of the Egyptians*.

Gospel of Nicodemus.—This title is first met with in the 13th century. It is used to designate an apocryphal writing entitled in the older MSS. “ὑπομήματα τοῦ Κυρίου ἡμῶν Ἰησοῦ Χριστοῦ πραχθέντα ἐπὶ Ποντίου Πιλάτου:” also “Gesta Salvatoris Domini . . . inventa Theodosio magno imperatore in Ierusalem in prætorio Pontii Pilati in codicibus publicis.” See Tischendorf, *Evangelia Apocrypha*², pp. 333-335. This work gives an account of the Passion (i.-xi.), the Resurrection (xii.-xvi.), and the *Descensus ad Inferos* (xvii.-xxvii.). Chapters i.-xvi. are extant in the Greek, Coptic, and two Armenian versions. The two Latin versions and a Byzantine recension of the Greek contain i.-xxvii. (see Tischendorf, *Evangelia Apocrypha*², pp. 210-458). All known texts go back to A.D. 425, if one may trust the reference to Theodosius. But this was only a revision, for as early as 376 Epiphanius (*Hæc.* i. 1) presupposes the existence of a like text. In 325 Eusebius (*H. E.* ii. 2) was acquainted only with the heathen *Acts of Pilate*, and knew nothing of a Christian work. Tischendorf and Hofmann, however, find evidence of its existence in Justin’s reference to the Ἄκτα Πιλάτου (*Apol.* i. 35, 48), and in Tertullian’s mention of the *Acta Pilati* (*Apol.* 21), and on this evidence attribute our texts to the first half of the 2nd century. But these references have been denied by Scholten, Lipsius, and Lightfoot. Recently Schubert has sought to derive the elements which are found in the Petrine Gospel, but not in the canonical gospels, from the original *Acta Pilati*, while Zahn exactly reverses the relation of these two works. Rendel Harris (1899) advocated the view that the Gospel of Nicodemus is a prose version of the Gospel of Nicodemus, written in Homeric centones as early as the 2nd century. Lipsius and Dobschütz relegate the book to the 4th century. The question is not settled yet (see Lipsius in Smith’s *Dict. of Christ. Biography*, ii. 708-709, and Dobschütz in *Hastings’ Bible Dictionary*, iii. 544-547).

Gospel of Peter.—Before 1892 we had some knowledge of this gospel. Thus Serapion, bishop of Antioch (A.D. 190-203), found it in use in the church of Rhossus in Cilicia, and condemned it as Docetic (Eusebius, *H. E.* vi. 12). Again Origen (*in Matt.* tom. xvii. 10) says that it represented the brethren of Christ as His half-brothers. In 1885 a long fragment was discovered at Akhmîm, and published by Bouriant in 1892, and subsequently by Lods, Robinson, Harnack, Zahn, Schubert, Swete. Harnack holds that Justin used this gospel, and hence assigns its composition to the beginning of the 2nd century; Sanday to 125, Zahn to 130, and Swete and Chase to 150.

Gospel of Thomas.—This gospel professes to give an account of our Lord’s boyhood. It appears in two recensions. The more complete recension bears the title Ὁμιλία Ἰσραηλίου Φιλοσόφου ῥητὰ εἰς τὰ παιδικὰ τοῦ Κυρίου, and treats of the period from the 7th to the 12th year (Tischendorf, *Evangelia Apocrypha*², 1876, 140-157). The more fragmentary recension gives the history of the childhood from the 5th to the 8th year, and is entitled Σύνγραμμα τοῦ ἁγίου ἀποστόλου Θωμᾶ περὶ τῆς παιδικῆς ἀνατροφῆς τοῦ Κυρίου (Tischendorf, *op. cit.* pp. 158-163). Two Latin translations have been published in this work by the same scholar—one on pp. 164-180, the other under the wrong title, *Pseudo-Matthæi Evangelium*, on pp. 93-112. A Syriac version, with an English translation, was published by Wright in 1875. This gospel was originally still more Docetic than it now is, according to Lipsius. Its present form is due to an orthodox revision which

discarded, so far as possible, all Gnostic traces. Lipsius (Smith’s *Dict. of Christ. Biog.* ii. 703) assigns it to the latter half of the 2nd century, but Zahn (*Gesch. Kan.* ii. 771), on good grounds, to the earlier half. The latter scholar shows that probably it was used by Justin (*Dial.* 88). At all events it circulated among the Marcosians (Irenæus, *Hæc.* i. 20) and the Naasenes (Hippolytus, *Refut.* v. 7), and subsequently among the Manichæans, and is frequently quoted from Origen downwards (*Hom. I. in Luc.*). If the stichometry of Nicephorus is right, the existing form of the book is merely fragmentary compared with its original compass.

Gospel of the Twelve.—This gospel, which Origen knew (*Hom. I. in Luc.*), is not to be identified with the *Gospel according to the Hebrews* (see above), with Lipsius and others, who have sought to reconstruct the original gospel from the surviving fragments of these two distinct works. The only surviving fragments of the *Gospel of the Twelve* have been preserved by Epiphanius (*Hæc.* xxx. 13-16, 22: see Preuschen, *op. cit.* 9-11). It began with an account of the baptism. It was used by the Ebionites, and was written, according to Zahn (*op. cit.* ii. 742), about A.D. 170.

II.—Acts and Teachings of the Apostles.

Acts of Andrew.—These acts (referred to by Euseb. *H. E.* iii. 25; Epiph. *Hæc.* xvii. 1, &c.) are ascribed to the authorship of Leucius. For a complete discussion of the various documents see Lipsius, *Apokryphen Apostelgeschichten*, i. 543-622; also James in *Hastings’ Bible Dict.* i. 92-93. The best texts are in Bonnet’s *Acta Apostolorum Apocrypha*, 1898, II. i. 1-127.

Acts of John.—These acts (*cf.* Eusebius, *H. E.* iii. 25; Epiph. *Hæc.* xvii. 1), which recount many marvellous acts of John, his exile, and death, spring from the same period and authorship as the *Acts of Peter*. For a discussion of this work see Zahn, *Gesch. Kanons*, ii. 856-865; Lipsius, *Apok. Apostelgesch.* i. 348-542. The only complete text is to be found in Bonnet, *Acta Apost. Apocrypha*, 1898, pp. 151-216. See James, *Anecdota*, ii. pp. i.-xxv., 1-25 (1897).

Acts of Paul.—These acts, which claim to have been written by Linus, are assigned by Zahn to the years 150-180. See *Gesch. Kanons*, ii. 865-891, and Lipsius, *Acta Apost. Apoc.* 1891; *Apok. Apostelgesch.* ii. 70 *sqq.*

Acts of Paul and Thecla.—These were written, according to Tertullian (*De Baptismo*, 17), by a presbyter of Asia, who was deposed from his office on account of his forgery. This, the earliest of Christian romances (probably before A.D. 150), recounts the adventures and sufferings of a virgin, Thecla of Iconium. Lipsius discovers Gnostic traits in the story, but these are denied by Zahn (*Gesch. Kanons*, ii. 902). See Lipsius, *op. cit.* ii. 424-467; Zahn (*op. cit.* ii. 892-910). The best text is that of Lipsius, *Acta Apost. Apoc.* 1891, i. 235-272. There are Syriac, Arabic, Ethiopic, and Slavonic versions.

Gnostic Acts of Peter.—These acts are first mentioned by Eusebius (*H. E.* iii. 3) by name, and first referred to by the African poet Commodian about A.D. 250. Yet Harnack assigns their composition to this period mainly on the ground that Hippolytus was not acquainted with them; but even were this assumption true, it would not prove the non-existence of the acts in question. The literary relationship between these acts and the Leucian *Acts of John* have been shown by Lipsius, Zahn, and James. According to Photius, moreover, the *Acts of Peter*, also, were composed by this same Leucius Charinus, who, according to Zahn (*Gesch. Kanons*, ii. 864), wrote about 160 (*op. cit.* p. 848). These acts deal with Peter’s victorious conflict with Simon Magus, and his subsequent

martyrdom at Rome under Nero. They are edited by Lipsius and Bonnet, *Acta Apostolorum Apocrypha*, 1891. See Zahn, *op. cit.* 832-855; James, *Apoc. Anec.* ii. pp. xxiv.-xxviii.; and Chase, in Hastings' *Bible Dict.* iii. 773-774.

Preaching of Peter.—This book (Ἡέρων κήρυγμα) gave the substance of a series of discourses spoken by one person in the name of the apostles. Clement of Alexandria quotes it several times as a genuine record of Peter's teaching. Heracleon had previously used it (see Origen, *In Evang. Johann.* tom. xiii. 17). It is spoken unfavourably of by Origen (*De Prin.* Præf. 8). It was probably in the hands of Justin and Aristides. Hence Zahn gives its date as 90-100 at latest; Dobschütz, as 100-110; and Harnack, as 110-130. The extant fragments contain sayings of Jesus, and warnings against Judaism and Polytheism. They have been edited by Hilgenfeld: *Nov. Test. extra Can.* 1884, iv. 51-65, and by von Dobschütz, *Das Kerygma Petri*, 1893. Salmon (*Dict. Christ. Biog.* iv. 329-330) thinks that this work is part of a larger work, *A Preaching of Peter and a Preaching of Paul*, implied in a statement of Lactantius (*Inst. Div.* iv. 21); but this view is contested by Zahn, see *Gesch. Kanons*, ii. 820-834, particularly pp. 827-828; Chase, in Hastings' *Bible Dict.* iv. 776.

Acts of Thomas.—This is one of the earliest and most famous of the Gnostic acts. It has been but slightly tampered with by orthodox hands. The Greek and Latin texts were edited by Bonnet in 1883, the Greek also by James, *Apoc. Anec.* ii. 28-45, and the Syriac by Wright. Photius ascribes their composition to Leucius Charinus—therefore to the 2nd century, but Lipsius assigns it to the early decades of the 3rd. (See Lipsius, *Apokryphen Apostelgeschichten*, i. 225-347.)

Teaching of the Twelve Apostles (q.v.).—This important work was discovered by Philotheos Bryennios in Constantinople and published in 1883. Since that date it has been frequently edited. The bibliography can be found in Schaff's and in Harnack's editions. The book divides itself into three parts. The first (i.-vi.) contains a body of ethical instruction which is founded on a Jewish and probably pre-Christian document, which forms the basis also of the *Epistle of Barnabas*. The second part consists of vii.-xv., and treats of church ritual and discipline; and the third part is eschatological, and deals with the Second Advent. The book is variously dated by different scholars: Zahn assigns it to the years A.D. 80-120; Harnack to 120-165; Lightfoot and Funk to 80-100; Salmon to 120. See Salmon in *Dict. of Christ. Biog.* iv. 806-815.

III.—Epistles.

The Abgarus Epistles.—These epistles are found in Eusebius (*H. E.* i. 3), who translated them from the Syriac. They are two in number, and purport to be a petition of Abgar Uchomo, king of Edessa, to Christ to visit Edessa, and Christ's answer, promising after His ascension to send one of His disciples, who should "cure thee of thy disease, and give eternal life and peace to thee and all thy people." Lipsius thinks that these letters were manufactured about the year 200. (See *Dict. Christ. Biog.* iv. 878-881, with the literature there mentioned.) The above correspondence, which appears also in Syriac, is woven with the legend of Addai or Thaddæus. The best critical edition of the Greek text will be found in Lipsius, *Acta Apostolorum Apocrypha*, 1891, pp. 279-283.

Pauline Epistles to the Laodiceans and the Alexandrians.—The first of these is found only in Latin. This, according to Lightfoot (see Colossians^s, 272-298) and Zahn, is a translation from the Greek. Such an epistle is mentioned in the Muratorian canon. See Zahn, *op. cit.*

ii. 566-585. The Epistle to the Alexandrians is mentioned only in the Muratorian canon. (See Zahn, ii. 586-592.)

Third Epistle of Paul to the Corinthians, and Epistle from the Corinthians to Paul.—These letters, which are still preserved in Armenian and Latin, are declared by Zahn to belong to the *Acts of Paul*. See *Gesch. Kanons*, ii. 592-611. On the Latin text see Carrière and Berger, *Correspondence apocr. de S. P. et des Corinthiens*, 1891; Vetter, *Der apokryphe 3 Korintherbrief*, 1894.

IV.—Apocalypses.

The five apocalypses in Tischendorf's *Apocalypses Apocrypha*, 1866—*Apoc. Mosis* (which belongs to the Adam literature), *Apoc. Esræ*, *Apoc. Pauli*, *Apoc. Johannis*, *Dormitio Mariæ*—are of too late a date to be considered here, though they are in some respects valuable as containing ancient elements.

Greek Apocalypse of Baruch.—This work is referred to by Origen, *De Princip.* II. iii. 6: "Denique etiam Baruch prophetæ librum in assertionis hujus testimonium vocant, quod ibi de septem mundis vel cælis evidentius indicatur." This book survives in two forms in Slavonic and Greek. The former was edited by Bonwetsch in 1896, in the *Nachrichten von der königl. Ges. der Wiss. zu Gött.* pp. 91-101; the latter by James in 1897 in *Anecdota*, ii. 84-94, with an introduction (pp. li.-lxxi.). Neither work represents exactly the book of which Origen writes, for the Slavonic mentions only two heavens and the Greek only five. As the original work is based on the Syriac *Apocalypse of Baruch* and the *Rest of the Words of Baruch*, its composition falls between A.D. 136 and 200, if we accept the date assigned by Rendel Harris to the latter. A German translation of the Greek appears in Kautzsch's *Apok. u. Pseud.* ii. 448-457.

Testament of Hezekiah.—This writing is fragmentary, and has been preserved merely as a constituent of the *Ascension of Isaiah*. To it belongs iii. 13^b-iv. 18 of that book. It is found under the above name, *Διαθήκη Ἐζεκιῶν*, only in *Cedrenus* i. 120-121, who quotes partially iv. 12, 14, and refers to iv. 15-18. This evidence is supported by i. 2^b-5^a of the book, which describes the contents of *Hezekiah's Vision*, and which was inserted by the editor to prepare for the vision recounted in iii. 13^b-iv. 18. This vision is definitely said to be Hezekiah's in i. 2, 4, and in the *Greek Legend*, i. 2, which is built on the *Ascension of Isaiah*. The book may have in part a Semitic background, as Semiticisms are found in iii. 27. It was written between A.D. 88 and 100. The ground for the earlier date is furnished by the form of the Antichrist myth which it attests. We have here Beliar incarnated as Antichrist in the form of the dead Nero. The *terminus ad quem* is supplied by iv. 13, according to which few of the personal disciples of Christ were still living when the author wrote. Hence we may reasonably fix this limit at A.D. 100 at latest. See Charles, *Ascension of Isaiah*, 1900. (For versions, editions, &c., see section on "Martyrdom of Isaiah," and Charles, *Ascension of Isaiah*, pp. xvi., xix.-xxviii.). This work gives us a sketch of the Church at the close of the 1st century. It bewails the fewness of the prophets, the prevalence of heresies, and the sad declension in Christian character. It touches incidentally on the Guilds, whose object was to keep believers in readiness for the advent of Christ, but expecting actually to experience first the dreaded coming of the Antichrist.

Oracles of Hystaspes.—This eschatological work (Χρήσεις Ὑρδασπου: so named by the anonymous 5th-century writer in Buresch, *Klaros*, 1889, p. 95) is mentioned in conjunction with the Sibyllines by Justin (*Apol.* i. 20), Clement of Alexandria (*Strom.* vi. 5), and Lac-

tantius (*Inst.* VII. xv. 19; xviii. 2-3). According to Lactantius, it prophesied the overthrow of Rome and the advent of Zeus to help the godly and destroy the wicked, but omitted all reference to the sending of the Son of God. According to Justin, it prophesied the destruction of the world by fire. According to the *Apocryph of Paul*, cited by Clement, Hystaspes foretold the conflict of the Messiah with many kings and His advent. Finally, an unknown 5th-century writer (see Buresch, *Klaros*, 1889, pp. 87-126) says that the *Oracles of Hystaspes* dealt with the incarnation of the Saviour. The work referred to in the last two writers has Christian elements, which were absent from it in Lactantius's copy. The lost oracles were therefore in all probability originally Jewish, and subsequently re-edited by a Christian.

Vision of Isaiah.—This writing has been preserved in its entirety in the *Ascension of Isaiah*, of which it constitutes chaps. vi.-xi. Before its incorporation in the latter work it circulated independently in Greek. Thus we have independent versions of these chapters in Latin and Slavonic. In the course of its incorporation in the *Ascension of Isaiah* it underwent certain changes to which we shall advert later. This work was written in Greek. In the 4th century two distinct recensions of this work already existed. The later of these, which contained 1 Cor. ii. 9 in xi. 34, was known to Jerome. This recension (now lost) was translated into Latin and Slavonic. The earlier recension is that which appears in

the *Ascension of Isaiah*, of which large fragments are preserved in the *Greek Legend*. This recension, which preserves several passages which are either abbreviated or omitted by the later recension, was translated into Ethiopic and Latin. Most of the latter version is lost. The original work was used by Ignatius and the author of the *Actus Petri Vercellenses*, and in part preserved in Epiphanius. Accordingly we assign its composition to the close of the 1st century A.D. (For the various texts, the translation and interpretation, see Charles, *Ascension of Isaiah*, 1900.) The *Vision of Isaiah* is valuable for the knowledge it affords us of 1st-century beliefs in certain circles as to the doctrines of the Trinity, the Incarnation, the Resurrection, and the Seven Heavens. (For the bibliography, see section on "Martyrdom of Isaiah," p. 487.)

Apocalypse of Peter.—Till 1892 only some five or more fragments of this book were known to exist. These are preserved in Clem. Alex. and in Macarius Magnes (see Hilgenfeld, *N. T. extra Can.* iv. 74 sqq.; Zahn, *Gesch. Kanons*, ii. 818-819). It is mentioned in the Muratorian Canon, and according to Eusebius (*H. E.* vi. 14. 1) was commented on by Clement of Alexandria. In the fragment found at Akhmim there is a prediction of the last things, and a vision of the abode and blessedness of the righteous, and of the abode and torments of the wicked. For further information see the editions of James, Lods (1892), Harnack, and Dieterich (1893).

Apostolical Constitutions.—The Apostolical Constitutions (*Διαταγαὶ Ὁρ Διατάξεις τῶν ἁγίων ἀποστόλων διὰ Κλήμεντος τοῦ Ῥωμαίων ἐπισκόπου τε καὶ πολιτοῦ. Καθολικὴ διδασκαλία*) are a collection of ecclesiastical regulations in eight books, the last of which concludes with the eighty-five *Canons of the Holy Apostles*. By their title the Constitutions profess to have been drawn up by the apostles, and to have been transmitted to the Church by Clement of Rome; sometimes the alleged authors are represented as speaking jointly, sometimes singly. From the first they have been very variously estimated; the *Canons*, as a rule, more highly than the rest of the work. For example, the Trullan Council of Constantinople (*quinti-sæcūm*) A.D. 692 accepts the *Canons* as genuine by its second canon, but rejects the Constitutions on the ground that spurious matter had been introduced into them by heretics; and whilst the former were henceforward used freely in the East, only a few portions of the latter found their way into the Greek and oriental law-books. Again, Dionysius Exiguus (c. A.D. 500) translated fifty of the *Canons* into Latin, although under the title *Canones qui dicuntur Apostolorum*, and thus they passed into other Western collections; whilst the Constitutions as a whole remained unknown in the West until they were published in 1563 by the Jesuit Turrianus. At first received with enthusiasm, their authenticity soon came to be impugned; and their true significance was largely lost sight of as it began to be realized that they were not what they claimed to be. Vain attempts were still made to rehabilitate them, and they were, in general, more highly estimated in England than elsewhere. The most extravagant estimate of all was that of Whiston, who calls them "the most sacred standard of Christianity, equal in authority to

the Gospels themselves, and superior in authority to the epistles of single apostles, some parts of them being our Saviour's own original laws delivered to the apostles, and the other parts the public acts of the apostles" (Historical preface to *Primitive Christianity Revived*, pp. 85-86). Others, however, realized their composite character from the first, and by degrees some of the component documents became known. Bishop Pearson was able to say that "the eight books of the Apostolic Constitutions have been after Epiphanius's time compiled and patched together out of the *didascalie* or doctrines which went under the names of the holy apostles and their disciples or successors" (*Vind. Ign.* i. cap. 5); whilst a greater scholar still, Archbishop Usher, had already gone much further, and concluded, forestalling the results of modern critical methods, that their compiler was none other than the compiler of the spurious Ignatian epistles (*Epp. Polyc. et Ign.* p. lxxiii. f., Oxon. 1644). The Apostolical Constitutions, then, are spurious, and they are one of a long series of documents of like character. But we have not really gauged their significance by saying that they are spurious. They are the last stage and climax of a gradual process of compilation and crystallization, so to speak, of unwritten church custom; and a short account of this process will show their real importance and value.

These documents are the outcome of a tendency which is found in every society, religious or secular, at some point in its history. The society begins by living in accordance with its fundamental principles. By degrees these translate themselves into appropriate action. Difficulties are faced and solved as they arise; and when similar circumstances recur they will tend to be met in the same way. Thus there grows up by degrees a body of what may be called customary law. Plainly, there is no particular point of time at which this customary law can be said to have begun. To all appearance it was there from the first in solution and gradually crystallizes out; and yet it is being continually modified as time goes on. Moreover, the time comes when

Origin
and real
nature.

the attempt is made, either by private individuals or by the society itself, to put this "customary law" into writing. Now when this is done, two tendencies will at once show themselves. (a) This "customary law" will at once become more definite: the very fact of putting it into writing will involve an effort after logical completeness. There will be a tendency on the part of the writer to fill up gaps; to state local customs as if they obtained universally; to introduce his personal equation, and to add to that which is the custom that which, in his opinion, ought to be. (b) There will be a strong tendency to fortify that which has been written with great names, especially in days when there is no very clear notion of literary property. This is done, not always with any deliberate consciousness of fraud (although it must be clearly recognized that truth is not one of the "natural virtues," and that the sense of the obligations of truthfulness was far from strong), but rather to emphasize the importance of what was written, and the fact that it was no new invention of the writer's. In a non-literary age fame gathers about great names; and that which, *ex hypothesi*, has gone on since the beginning of things is naturally attributed to the founders of the society. Then come interpolations to make this ascription more probable, and the prefixing of a title, then or subsequently, which states it as a fact. This is precisely the way in which the Apostolical Constitutions and other kindred documents have come into being. They are attempts, made in various places and at different times, to put into writing the order and discipline and character of the Church; in part for private instruction and edification, but in part also with a view to actual use; frequently even with an actual reference to particular circumstances. In this lies their importance, to a degree which has scarcely been adequately realized yet. They contain evidence of the utmost value as to the order of the Church in early days; evidence, however, which needs to be sifted with the greatest care, since the personal preferences of the writer and the customs of the local church to which he belongs are continually mixed up with things which have a wider prevalence. It is only by careful investigation, by the method of comparisons, that these elements can be disentangled; but as the number of documents of this class known to us is continually increasing, their value increases even more than proportionately. And whilst their local and fugitive character must be fully recognized and allowed for, it is unjustifiable to set them aside or leave them out of account as heretical, and therefore negligible.

It will be sufficient here to mention shortly the chief collections of this kind which came into existence during the first four centuries; generally as the work of private individuals, and having, at any rate, no more than a local authority of some kind.

Other collections. (a) The earliest known to us is the *Didache* or *Teaching of the Twelve Apostles*, itself compiled from earlier materials, and dating from, at any rate, the earlier half of the 2nd century [TEACHING OF THE APOSTLES]. (b) The Apostolical Church Order (*apostolische Kirchenordnung* of German writers); "Ecclesiastical Canons of the Holy Apostles" of one MS.; *Sententiae Apostolorum* of Pitra: of the 3rd century, and emanating probably from Upper Egypt. Its earlier part, cc. 1-14, depends upon the *Didache*, and the rest of it is a book of discipline in which Harnack has attempted to distinguish two older fragments of church law (*Texte u. Unters.* ii. 5). (c) The so-called *Canones Hippolyti*, probably Egyptian or Roman and of the beginning of the 3rd century. It will be observed that these make no claim to apostolic authorship; but otherwise their origin is like that of the rest, unless indeed, as has been suggested, they represent the work

of an actual Roman synod. (d) The so-called *Egyptian Church Order*, now extant only in a fragmentary Latin version recently published by Hauler, and as part of two larger collections; the former (sometimes called the Egyptian Church Ordinances) being cc. 31-62 of the Sahidic *Ecclesiastical Canons*, and the latter being stat. 21-71 of the Ethiopic *Statutes of the Apostles*. It is apparently of the end of the 3rd century or beginning of the 4th. (e) The recently-discovered *Testament of the Lord*, which is somewhat later in date, and likewise depends upon the *Canones Hippolyti* [TESTAMENT OF THE LORD]. (f) The so-called *Canons of Basil*. [On the relations between the four last-named, see CANONS OF HIPPOLYTUS.] (g) The *Didascalia Apostolorum*, originally written in Greek, but known through a Syriac version and a fragmentary Latin one published by Hauler. It is of the middle of the 3rd century—in fact, a passage in the Latin translation seems to give us the date A.D. 254. It emanates from Palestine or Syria, and is independent of the documents already mentioned; and upon it, as we shall see, the *Constitutions* themselves very largely depend. (h) A number of shorter fragments, published by Lagarde, Pitra, and others. (i) *The Apostolical Constitutions*.—At a later date various collections were made of the documents above mentioned, or some of them, to serve as law-books in different churches—*e.g.*, the Syrian Octateuch, the Egyptian Heptateuch, and the Ethiopic *Simōdōs*. These, however, stand on an entirely different footing, since they are simply collections of existing documents, and no attempt is made to claim apostolic authorship for them.

The *Constitutions* themselves fall into three main divisions. (i.) The first of these consists of books i.-vi., and throughout runs parallel to the *Didascalia*. Bickell, indeed, held that this latter was an abbreviated form of books i.-vi.; but it is now agreed on all hands that the *Constitutions* are based on the *Didascalia* and not *vice versa*. (ii.) Then follows book vii., the first thirty-one chapters of which are an adaptation of the *Didache*, whilst the rest contain various liturgical forms of which the origin is still uncertain, though it has been acutely suggested by Achelis, and with great probability, that they originated in the schismatical congregation of Lucian at Antioch. (iii.) Book viii. is more composite, and falls into three parts. The first two chapters, *περὶ χαρισμάτων*, may be based upon a lost work of St Hippolytus, otherwise known only by a reference to it in the preface of the Latin version of the *Egyptian Church Order*; and an examination shows that this is highly probable. The next section, cc. 3-27, *περὶ χειροτονιῶν*, and cc. 28-46, *περὶ κανόνων*, is twofold, and is evidently that upon which the writer sets most store. The apostles no longer speak jointly, but one by one in an apostolic council, and the section closes with a joint decree of them all. They speak of the ordination of bishops (the so-called Clementine Liturgy is that which is directed to be used at the consecration of a bishop, cc. 5-15), of presbyters, deacons, deaconesses, sub-deacons, and lectors, and then pass on to confessors, virgins, widows, and exorcists; after which follows a series of canons on various subjects, and liturgical formulæ. With regard to this section, all that can be said is that it includes materials which are also to be found elsewhere—in the *Egyptian Church Order* and other documents already spoken of—and that the precise relation between them is at present not determined. The third section consists of the Apostolical Canons already referred to, the last and most significant of which places the *Constitutions* and the two epistles of Clement in the canon of Scripture, and omits the Apocalypse. They are derived in part from the preceding *Constitutions*, in part from the canons of the councils of Antioch, 341, Nicaea, 325, and possibly Laodicea.

A comparison of the Constitutions with the material upon which they are based will illustrate the compiler's method. (a) To begin with the *Didascalia*. It is unmethodical and badly digested, homiletical in style, and abounding in Biblical quotations. There is no precise arrangement; but the subjects, following a general introduction, are the bishop and his duties, penance, the administration of the offerings, the settlement of disputes, the divine service, the order of widows, deacons and deaconesses, the poor, behaviour in persecution, and so forth. The compiler of the Constitutions finds here material after his own heart. He is even more discursive and more homiletical in style; he adds fresh citations of the Scriptures, and additional explanations and moral reflexions; and all this with so little judgment that he often leaves confusion worse confounded (e.g., in ii. 57, where, upon a symbolical description of the Church as a sheepfold, he has superimposed the further symbolism of a ship). (b) Passing on to books vii. and viii., we observe that the compiler's method of necessity changes with his new material. In the former book he still makes large additions and alterations, but there is less scope for his prolixity than before; and in the latter, where he is no longer dealing with generalities, but making actual definitions, the Constitutions of necessity become more precise and statutory in form. Throughout he adopts and adapts the language of his sources as far as possible, "only pruning in the most pressing cases," but towards the end he cannot avoid making larger alterations from time to time. And his alterations throughout are not made aimlessly. Where he finds things which would obviously clash with the customs of his own day, he unhesitatingly modifies them. An account of the Passion, with a curiously perverted chronology, the object of which was to justify the length of the Passion-tide fast, is entirely revised for this reason (v. 14); the direction to observe Easter according to the Jewish computation is changed into the exact contrary for the same reason (v. 17); and where his archetype lapses into speaking of a lull in persecution he naïvely informs us that the Romans have now given up persecuting and have adopted Christianity (vi. 26), forgetting altogether that he is speaking in the character of the apostles. Above all, he both magnifies the office of the Christian ministry as a whole and alters what is said of it in detail (for example, the deaconess loses rank not a little), to make it agree with the circumstances of his day in general, and with his own ideas of fitness in particular. It is here that his evidence is at once most valuable and needing to be used with the greatest care. To give one striking example of the value of these documents. The *Canones Hippolyti* (vi. 43) provide that one who has been a confessor for the faith may be received as a presbyter by virtue of his confessorship and not by the laying on of the bishop's hands; but if he be chosen a bishop, he is to be ordained. This provision passes on into the Egyptian *Ecclesiastical Canons* and other kindred documents, and even into the *Testamentum Domini*. But the corresponding passage in the Apostolical Constitutions (viii. 23) entirely reverses it: "A confessor is not ordained, for he is so by choice and patience, and is worthy of great honour. . . . But if there be occasion, he is to be ordained either a bishop, priest, or deacon. But if any one of the confessors who is not ordained snatches to himself any such dignity upon account of his confession, let the same person be deprived and rejected; for he is not in such an office, since he has denied the constitution of Christ, and is worse than an infidel."

Who, then, is the author of the Constitutions, and what can be inferred with regard to him? (i.) By separating off the sources which he used from his own additions to them, it at once becomes clear that the latter are the

work of one man: the style is unmistakable, and the method of working is the same throughout. The compiler of books i.-vi. is also the compiler of books vii., viii. (ii.) As to his theological position, different views have been held. Funk suggests Apollinarianism, which is the refuge of the destitute; and Achelis inclines in the same direction. But the affinities of the author are quite otherwise, the most pronounced of them being a strong subordinationist tendency, denial of a human soul to Christ, and the like, which suggest not indeed Arianism but an inclination towards Arianism. Above all, his polemic is directed against the dying heresies of the 3rd century; and he writes with an absence of constraint which is not the language of one who lives amidst violent controversies or who is conscious of being in a minority. All this points to the position of a "conservative" or semi-Arian of the East, one who belongs, perhaps, to the circle of Lucian of Antioch and writes before the time of Julian. It is hard to think of any other time or circumstances in which a man could write like this. (iii.) The indications of *time* have been held to point to a different conclusion. On the one hand, the fact that the attempt to rebuild the temple by Julian in 363 is not mentioned in vi. 24 points to an earlier date; and the fact the *κομιάραι* are not mentioned amongst the church officers points in the same direction, for elsewhere they are first mentioned in a rescript of Constantius in A.D. 357. On the other hand, in the cycle of feasts occur the names of several which are probably of later date—e.g., Christmas and St Stephen, which were introduced at Antioch c. A.D. 378 and 379 respectively. Again, Epiphanius (c. A.D. 374) appears to be unacquainted with it; he still quotes from the *Didascalia*, and elaborately explains it away where it is contrary to the usages of his own day. But as regards the former point, it is possible that the Apostolical Constitutions actually gave rise to these festivals; or, on the other hand, that the two passages were subsequently introduced either by the writer himself or by some other hand, when the last book of the Constitutions was being used as a law-book. And as regards the latter, the fact that Epiphanius does not use the Constitutions is no proof that they had not yet been compiled. (iv.) As to the region of composition there is no real doubt. It was clearly the East, Syria or Palestine. Many indications are against the latter, and Syria is strongly suggested by the use of the Syro-Macedonian calendar. Moreover, the writer represents the Roman Clement as the channel of communication between the apostles and the Church. This fact both supplies him with the name by which he is commonly known, Pseudo-Clement, and also furnishes corroboration of his Syrian birth; since the other spurious writings bearing the name of Clement, the *Homilies* and *Recognitions*, are likewise of Syrian origin. Moreover, the spurious Ignatian epistles, which are also Syrian, depend throughout upon the Constitutions. (v.) But this is not all. It was long ago noticed that Pseudo-Clement bears a very close resemblance to Pseudo-Ignatius. Usher, as we have seen, identified them, and modern criticism accepts this identification as a fact (Lagarde, Harnack, Funk, Brightman). Lightfoot, indeed, still hesitated (*Ap. Fathers* ii. i. 266 n.) on the ground that Pseudo-Ignatius occasionally misunderstands the Constitutions, that the two writings give the Roman succession differently, and that Pseudo-Clement shows no knowledge of the Christological controversies of Nicaea. But as regards the first of these, it is rather a case of condensed citation than of misinterpretation; the second is explained by the writer's carelessness as shown in other passages, and all are solved if a considerable interval of time elapsed between the compilation of the Constitutions and the spurious Ignatian epistles.

It is clear then that the compiler was a Syrian, and that

he also wrote the spurious Ignatian epistles; he was likewise probably a semi-Arian of the school of Lucian of Antioch. His date is given by Harnack as A.D. 340-360, with a leaning to 340-343; by Lightfoot as the latter half of the 4th century; by Brightman, 370-380; and by Funk as the beginning of the 5th century. The present writer holds to the first-named of these—i.e., 340-360.

Appendicitis.—In medical nomenclature the termination "itis" is used to signify inflammation, and is arbitrarily tacked on to the end of any word, whether of Greek or Latin origin. On this principle "appendicitis" has been coined to designate inflammation connected with that part of the intestine which is known as the "appendix." There is no reason to suppose that the affection is more common than it used to be; but it is now better understood and more frequently recognized, and the development of modern abdominal surgery has brought it into prominence. It was formerly included under the term "perityphlitis"—that is, inflammation connected with the "cæcum," a portion of the large intestine,—and some authorities still prefer that term as more scientifically accurate; but it is now generally recognized that in the vast majority of cases the inflammation begins in the appendix, not in the intestine proper. From the appendix it extends to the surrounding peritoneum and sets up a localized peritonitis, which in the worst cases may become general.

The appendix is a narrow tube, normally about the size of a goose quill, and from 1 inch to 5 or 6 inches in length. The average length is 3 inches. It terminates in a blunt point, and from its worm-like shape is called the *appendix vermiformis*. It is an appendage of the large intestine, into which it opens. It is not known to perform any functions, and is regarded as the degenerate relic, surviving in man and other mammals, of an earlier form of intestine. Owing to its shape, character, and situation the appendix is frequently the seat of morbid changes. They have been observed in one-third of a number of bodies examined *post mortem*. Inflammation

LARGE INTESTINE SHOWING VERMIFORM APPENDIX (v.a.) AND CÆCUM (c.).

is set up in various ways. Foreign bodies passing down the intestinal canal may find their way into the appendix and lodge there. This was formerly believed to be the chief cause of mischief; hence the warning, familiar to every child, against the danger of swallowing cherry stones

and other small, hard objects. Extended knowledge, however, has shown that such foreign bodies are only present in a small minority of cases. More frequently the tube is found blocked by hardened fæces or undigested particles of food, such as nuts, cheese, fibrous vegetable matter, and other imperfectly masticated substances. Sometimes calcareous concretions are formed round a nucleus furnished by some small body. Inflammation may occur, however, without any of these things. The tube may be twisted or otherwise strangulated, leading to gangrene; or the orifice may be closed in a similar manner, so that the tube becomes greatly distended with mucus, which can find no outlet; or ulceration of tuberculous origin may occur. In all cases inflammation started in the appendix is liable to spread to the surrounding membranes, and herein lies the gravity of the affection.

For clinical purposes several varieties of appendicitis may conveniently be distinguished according to the degree and course of the inflammation: (1) simple inflammation, commonly called "catarrhal"; (2) ulcerative; (3) perforative; (4) relapsing; (5) chronic.

The symptoms vary accordingly within wide limits, ranging from slight pain and sickness, which pass off in a day or two, to an exceedingly violent illness, which may cause death in a few hours. (1) Simple inflammation. In a well-defined case the onset is sudden. Pain is felt in the belly, low down on the right side (the right iliac fossa), or across the front; it is often described as "radiating." There is some fever, the temperature rising to 101° or 102° F., with constipation, nausea, and very likely vomiting. The abdomen is tender to pressure, and the tenderness may be referred to a particular spot. Some swelling may also be made out. The attack lasts for two, three, or four days, and then subsides. There are, however, other cases less well defined, in which the mischief pursues a latent course, producing little more than a vague abdominal uneasiness, until it suddenly advances into a more violent stage. (2) The illness assumes a more acute form, and all the symptoms are more severe. There may be an initial rigor; the temperature rises to 104° or higher, with great prostration, severe pain, and complete loss of appetite. An unpleasant taste in the mouth is often observed; vomiting may persist and become faecal. Abdominal tenderness is more marked and general, and swelling more obvious. The patient lies with legs drawn up, so as to ease pressure on the abdomen and lessen pain. The attack may subside or go on to the suppuration and the formation of an abscess. (3) If the abscess break into the general abdominal cavity, there is sudden and violent pain with collapse. The condition is one of extreme gravity. Death usually follows within forty-eight hours, and recovery is very rare. (4) Some persons are subject to recurrent attacks of appendicitis, and to this variety of the disease the term "relapsing" is applied. Such attacks do not differ in character from those previously described. They are no doubt due to some standing condition of the appendix coupled with imperfect performance of the digestive functions, but they only occur at intervals, and between the attacks the patient is well. (5) The chronic form of appendicitis differs from the relapsing in that the patient is never well, but always suffers from more or less uneasiness, which is liable to develop into an acute attack.

With regard to treatment it is obvious that, however mild an attack may be, an affection liable to assume such grave forms is not to be trifled with and demands early medical assistance. In the milder cases the measures indicated are rest in bed, hot fomentations or poultices to the abdomen, and opiates to relieve pain and keep the intestine quiet. Leeches over the abdomen give much relief. Food should be hot, fluid, and given in small

quantities. Ice and milk are not suitable. Solid food should not be given until fever has abated and distinct improvement set in. Great care should be exercised in the administration of aperients, and as this is a matter which patients or their friends are apt to take into their own hands it is necessary to give an emphatic warning against the practice so long as the symptoms described are present. The safest course is to eschew aperients altogether. In cases of moderate severity it may be desirable to open the bowels, but this is best accomplished by enemata.

In the majority of cases the foregoing measures will suffice, but when the attack pursues an unfavourable course the question of operative interference arises. There is a considerable difference of opinion among surgeons on the point. Some advocate early operation in all cases; others, of a more conservative tendency, prefer to give the inflammation an opportunity of subsiding without interference, and hold that in uncomplicated cases it only becomes necessary when the symptoms persist after the fifth day. Perhaps the soundest rule is to operate in all doubtful cases. Removal of the appendix in persons liable to recurrent attacks has been practised with great success, and may be regarded as one of the triumphs of modern surgery. The danger of relapse may, however, be guarded against by less drastic means. Persons who have had an attack should attend to their mastication and be careful about diet. In particular, they should avoid indigestible substances, and counteract any tendency to constipation. Exercise and abdominal massage are recommended, but the advisability of the latter is open to question.

The prognosis in appendicitis is generally favourable. The "case mortality" is believed to be about 5 per cent., but in the graver forms it is very much higher. Men are said to be more liable to attack than women. It has been suggested that some constitutional states, such as a rheumatic or gouty tendency, predispose to appendicitis, but the theory is not supported by any substantial evidence.

Affections with which appendicitis is liable to be confounded are acute intestinal obstruction, typhoid fever, renal and gall-stone colic. The first of these resembles it most closely, and diagnosis is sometimes very difficult. In typhoid fever the characteristic temperature, the general condition of the patient, and the presence of delirium are differentiating signs of importance; in renal and gall-stone colic the situation and more paroxysmal character of the pain are usually distinctive. (See also SURGERY.)

(A. SL.)

Appenzell, one of the Swiss cantons, since 1597 divided into the two half cantons of Ausser Rhoden and Inner Rhoden, the joint total area of which is 161·8 sq. miles. Of this Ausser Rhoden claims 100½ sq. miles, 97·8 sq. miles being classed as "productive," forests covering 18·1 sq. miles, and vineyards 0·1 sq. mile, while of the 2·7 "unproductive" sq. miles, eternal snows cover 0·3 sq. mile. Inner Rhoden has an area of 61·3 sq. miles, of which 56·7 sq. miles are classed as "productive," forests covering 2·7 sq. miles, while of the "unproductive" 4·6 sq. miles 38 is occupied by eternal snows. The population of Ausser Rhoden was in 1880, 51,953; in 1888, 54,109; and in 1900, 55,284, or 551 per sq. mile; of Inner Rhoden the population was in 1880, 12,874; in 1888, 12,874; and in 1900, 13,486, or 220 per sq. mile. The rate of density in the former is only exceeded in Switzerland by Geneva, and Basel Stadt (Bâle Ville). In 1900 there were in Ausser Rhoden but 580 Italian-speaking (in Inner Rhoden, 78) and 86 (in Inner Rhoden only 4) French-

speaking inhabitants, the rest being German-speaking. The religious statistics are as follows: (1900), Ausser Rhoden—Protestants, 49,741; Romanists, 5501; Jews, 31; Inner Rhoden—Protestants, 830; Romanists, 12,653.

The loftiest point in the canton is the Säntis, 8216 feet, now crowned by an observatory and an inn. The political capital of Ausser Rhoden is Herisau, while that of Inner Rhoden is Appenzell. Both halves of the canton still preserve their primitive democratic assemblies. In 1897, the state revenue of Ausser Rhoden was 640,162 francs (an increase of 100 per cent. since 1885), and the state expenditure 613,337 francs (an increase of 61 per cent. since 1885), while in 1898 the surplus was 18,490 francs; the state debt in 1897 was nil. In 1897, Inner Rhoden had a state revenue of 181,932 francs (an increase of nearly 72 per cent. since 1885), and a state expenditure of 165,409 francs (an increase of 64 per cent. since 1885), but in 1898 there was a deficit of 24,544 francs; in 1897 there was no public debt. In 1899, the mountain pastures or "alps" of Inner Rhoden were 168 in number, and capable of supporting 4008 cows, while the capital value was put at 2,682,955 francs; accurate statistics have not yet been published as regards Ausser Rhoden.

Appenzell, the chief town of the above canton, situated in Inner Rhoden. The two convents are both Capuchin, that of the men dating from 1588, and that of the women being a few years later in date. The "Teufel" flag was captured from the Tyrolese in 1406 at Imst, near Landeck. In 1888, the population of Appenzell (which is rather a large village than a town) was 4472, and in 1899 was put at 4369.

Appleby, a municipal borough (1885), market-town and county town of Westmoreland, England, on the Eden, 13 miles S.E. of Penrith, in the Appleby parliamentary division of the county. Station on the Midland railway. The bridge over the Eden has been rebuilt. Two Wesleyan chapels and new grammar school buildings are modern erections. Area, 1855 acres; population (1881), 1855; (1891), 1776; (1901), 1764.

Appleton, a city of Wisconsin, U.S.A., the capital of Outagamie county, situated in 44° 16' N. lat. and 88° 24' W. long., at an altitude of 718 feet, in the eastern part of the state, at the Grand Chute on Lower Fox river, which supplies excellent water-power for lumber and paper manufactures. The plan of the city is regular, and it is divided into six wards. It is entered by the Chicago and North-western and the Chicago, Milwaukee, and St Paul railways. It is the seat of Lawrence University. The city received its name from Samuel Appleton, who was one of its founders, and a leading spirit in the organization of Lawrence University. Population (1880), 8005; (1890), 11,869; (1900), 15,085.

Appomattox, a village of Appomattox county, Virginia, U.S.A., formerly the capital. It is situated in southern Virginia, on the Norfolk and Western railway. It is noted as the scene of the surrender of the army of northern Virginia under General Lee to the Federal forces under Grant on 9th April 1865.

Apportionment.—The term "apportionment" is used in law in a variety of senses:—(i.) Sometimes it is employed, roughly and with no technical meaning, to

indicate the distribution of a benefit (*e.g.*, salvage), or the incidence of a duty (*e.g.*, obligations as to the maintenance of highways); (ii.) In its strict legal interpretation it falls into two classes, "apportionment in respect of estate" and "apportionment in respect of time." Where a lessee is evicted from, or surrenders, or forfeits possession of part of the property leased to him, he becomes liable at common law to pay only a rent apportioned to the value of the interest which he still retains. So where the person entitled to the reversion of an estate assigns part of it, the right to an apportioned part of the rent incident to the whole reversion passes to his assignee. In each of these cases there is said to be "apportionment in respect of estate." Apportionment of this description may be brought about not only, as in the cases above noted, by the act of the parties, but also by operation of law, or by the "act of God" (as, for instance, where part of an estate is submerged by the encroachments of the sea); and to the same category belongs the apportionment which takes place under various statutes (*e.g.*, the Lands Clauses Act, 1845), when land is required for public purposes. Under the Apportionment Act, 1870, rents, annuities, dividends, and other payments at fixed periods, are to be considered as accruing from day to day, and to be apportionable accordingly. This is "apportionment in respect of time." The cases to which it applies are mainly cases of either (a) apportionment of rent due under leases where at a time between the dates fixed for payment the lessor or lessee dies, or some other alteration in the position of parties occurs; or (b) apportionment of income between the representatives of a limited owner and the remainderman when the limited interest determines at a time between the date when such income became due. (A. W. E.)

Apulia, Italian *Puglia*, a territorial division of Italy, stretching from Monte Gargano to the extremity of the "heel," and embracing the provinces of Bari, Foggia, and Lecce, with an area of 7376 sq. miles and a population of 1,589,064 (1881), and 1,929,723 (1899). It is a treeless plain, growing corn and feeding sheep, the principal wealth of the inhabitants. The products next in importance are oats, barley, olives, wine, lemons, oranges, tobacco, and figs. Salt, limestone, and other building stone are extracted. Wool is a source of wealth. Distilleries (66 in 1899, producing 146,775 gallons of pure spirit), olive-oil mills, the manufacture of casks and porcelain, iron-works and foundries are the most important of the industries. The principal ports are Brindisi, Gallipoli, Taranto, Bari, Barletta, Molfetta, Manfredonia, Trani, Bisceglie, Mola di Bari, and Monopoli. Apart from these, the more important towns are Lecce, Foggia, Bitonto, San Severo, Cerignola, Andria, and Terlizzi.

Apure. See ORINOCO.

Apurimac, an interior department of southern Peru, with an area of 8187 square miles and a population officially estimated at 177,387 in 1896. It embraces five provinces, Andahuaylas, Abancay, Cotabambas, Aymaraes, and Antabamba. The principal towns are Andahuaylas and Abancay.

Aquaria for a marine flora and fauna, which in 1875 (the date of the article on this subject in the ninth edition of this Encyclopædia) were little more than domestic toys, or show-places of a popular character, have of late years not only assumed a profound scientific importance for the convenient study of anatomical and physiological problems in marine botany and zoology, but have also attained an economic value, as offering the best opportunities for that study of the habits and environment

of marketable food-fish without which no steps for the improvement of sea-fisheries can be safely taken. The numerous "zoological stations" which have sprung up, chiefly in Europe and the United States, but also in the British colonies and Japan, often endeavour to unite these two aims, and have in many cases become centres of experimental work in problems relating to fisheries, as well as in less directly practical subjects. Of these stations, the oldest and the most important is that at Naples, which, though designed for purely scientific objects, also encourages popular study by means of a public aquarium. The following account of this station from the pen of Dr Giesbrecht, a member of the staff, will serve to show the methods and aims, and the complex and expensive equipment of a modern aquarium:—

The zoological station at Naples is an institution for the advancement of biological science—that is, of comparative anatomy, zoology, botany, physiology. It serves this end by providing the biologist with the various objects of his study and the necessary appliances; it is not a teaching institution. The station was founded by Dr Anton Dohrn, and opened in the spring of 1874; it is the oldest and largest of all biological stations, of which there are now about thirty in existence. Its two buildings are situated near the seashore in the western town park (Villa Nazionale) of Naples. The older and larger one, 33 metres long, 24 m. deep, 16 m. high, contains on the ground floor the aquarium, which is open to the public. On the first floor there is, facing south, the principal library, ornamented with fresco paintings, and, facing north, a large hall containing twelve working tables, several smaller rooms, and the secretarial offices. On the second floor is the physiological laboratory, and on the third floor the small library, a hall with several working tables, and the dark rooms used in developing photographs. The ground floor of the smaller building, which was finished in 1887, contains the rooms in which the animals are delivered, sorted, and preserved, and the fishing tackle kept, together with the workshop of the engineer; on the first and second floors are work-rooms, amongst others the botanical laboratory; on the third floor are store-rooms. In the basement of both buildings, which is continued underneath the court, there are sea-water cisterns and filters, engines, and store-rooms. The materials for study which the station offers to the biologist are specimens of marine animals and plants which abound in the western part of the Mediterranean, and especially in the Gulf of Naples. To obtain these, two screw-steamers and several rowing boats are required, which are moored in the harbour of Mergellina, situated close by. The larger steamer, *Johannes Müller* (15 m. long, 2½ m. wide, 1 m. draught), which can steam eight to ten English miles per hour, is provided with a steam dredge working to a depth of eighty fathoms. From the small steamer, *Frank Balfour*, and the rowing boats, the fishing is done by means of tow-nets. Besides these there are fishermen and others who daily supply living material for study. The plankton (small floating animals) is distributed in the morning, other animals as required. The animals brought in by the fishermen are at once distributed amongst the biologists, whereas the material brought up by the dredges is placed in flat revolving wooden vessels, so as to give the smaller animals time to come out of their hiding-places. The students who work in the station have the first claim on specimens of plants and animals; but specimens are also supplied to museums, laboratories, and schools, and to individuals engaged in original research elsewhere. Up to the present time about 4000 such parcels have been despatched, and not infrequently live specimens of animals are sent to distant places. This side of the work has been of very great value to science. The principal appliances for study with which the station provides the biologist are work-rooms furnished with the apparatus and chemicals necessary for anatomical research and physiological experiments and tanks. Every student receives a tank for his own special use. The large tanks of the principal aquarium are also at his disposal for purposes of observation and experiment if necessary.

The water in the tanks is kept fresh by continual circulation, and is thus charged with the oxygen necessary to the life of the organisms. It is not pumped into the tanks directly from the sea, but from three large cisterns (containing 300 cubic metres), to which it again returns from the tanks. The water wasted or evaporated during this process is replaced by new water pumped into the cisterns directly from the sea. The water flows from the large cisterns into a smaller cistern, from which it is distributed by means of an electric pump through vulcanite or lead pipes to the various tanks. The water with which the tanks on the upper floors are filled is first pumped into large wooden tanks placed beneath the roof, thence it flows, under

almost constant pressure, into the tanks. The water circulated in this manner contains by far the largest number of such animals as are capable of living in captivity in good condition. Some of them even increase at an undesirable rate, and it sometimes happens that young *Mytilus* or *Ciona* stop up the pipes; in laying these, therefore, due regard must be had to the arrangements for cleaning. For the cultivation of very delicate animals it is necessary to keep the water absolutely free from harmful bacteria; for this purpose large sand-filters have lately been placed in the system, through which the water passes after leaving the cisterns. Each of the smaller cisterns, which are fixed in the work-rooms, consists of two water-tanks, placed one above the other; their frames are of wrought iron and the walls generally of glass. Vessels containing minute animals can be placed between these two tanks, receiving their water through a siphon from the upper tank; the water afterwards flows away into the lower tank.

The twenty-six tanks of the public aquarium (the largest of which contains 112 cubic metres of water) have stone walls, the front portion alone being made of glass. As the tanks hold a very large number of animals in proportion to the quantity of water, they require to be well aerated. The pipes through which the water is conducted are therefore placed above the surface of the water, and the fresh supply is driven through them under strong pressure. A large quantity of air in the form of fine bubbles is thus taken to the bottom of the tank and distributed through the entire mass of water. Should the organisms which it is desired to keep alive be very minute, there is a danger of their being washed away by the circulating water. To obviate this, either the water which flows away is passed through a strainer, or the water is not changed at all, air being driven through it by means of an apparatus put into motion by the drinking-water supply.

The library contains about 9000 volumes, which students use with the help of a slip catalogue, arranged according to authors. The station has published at intervals since 1879 two periodicals treating of the organisms of the Mediterranean. One is *Fauna und Flora des Golfes von Neapel*, the other *Mittheilungen aus der Zoologischen Station zu Neapel*. The former consists of monographs in which special groups of animals and plants are most exhaustively treated and the Mediterranean species portrayed according to life in natural colours; up to the present time twenty-one zoological and five botanical monographs have appeared, making altogether 1200 4to sheets with about 400 plates. Of the *Mittheilungen*, which contain smaller articles on organisms of the Mediterranean, fourteen volumes in 8vo have been published. The station also publishes a *Zoologischer Jahresbericht*, which at first treated of the entire field of zoology, but since 1886 has been confined principally to Comparative Anatomy and Ontogeny; it appears eight to nine months after the end of the year reported. The *Guide to the Aquarium*, with its descriptions and numerous pictures, is meant to give the lay visitor an idea of the marine animal world.

There are about forty officials, amongst them six zoologists, one physiologist, one secretary, two draughtsmen, one engineer. The station is a private institution, open to biologists of all nations under the following conditions: there are agreements with the Governments of Austria, Baden, Bavaria, Belgium, Hamburg, Holland, Hesse, Italy, Prussia, Russia, Saxony, Switzerland, Hungary, Wurtemberg, the province of Naples, and the Universities of Cambridge, Oxford, Strassburg, Columbia College (New York), and the British Association for the Advancement of Science, the Smithsonian Institute, and a society of women in the United States of North America (formerly also with Bulgaria, Rumania, Spain, the Academy of Sciences in Berlin, Williams College, University of Pennsylvania), by virtue of which the Governments and corporate bodies named have the right, on payment of £100 per annum, to send a worker to the station; this places at his disposal a "table" or workplace, furnished with all the necessary appliances and materials as set down in the agreement. At present there are agreements for thirty-three tables, and since the foundation of the station nearly 1200 biologists have worked there. The current expenses are paid out of the table-rents, the entrance fees to the public aquarium, and an annual subvention paid by the German Empire.

In England a station on similar lines, but on a smaller scale, is maintained at Plymouth by the Marine Biological Association of the United Kingdom, with the help of subsidies from the Government and the Fishmongers' Company.

Little difficulty is experienced in maintaining, breeding, and rearing fresh-water animals in captivity, but for many various reasons it is only by unremitting attention and foresight that most marine animals can be kept even

alive in aquaria, and very few indeed can be maintained in a condition healthy enough to breed. Much experience, however, has been gained of late years at considerable expense, both at home and abroad. In starting a marine aquarium of whatever size, it should be obvious that the first consideration must be a supply of the purest possible water, as free as may be, not only from land-drainage and sewage, but also from such suspended matters as chalk, fine sand, or mud. This is most ideally and economically secured by placing the station a few feet above high-water mark, in as sheltered a position as possible, on a rocky coast, pumping from the sea to a large reservoir above the station, and allowing the water to circulate gently thence through the tanks by gravity (Ban-yuls). At an inland aquarium (Berlin, Hamburg), given pure water in the first instance, excellent if less complete results may nevertheless be obtained. The next consideration is the method by which oxygen is to be supplied to the organisms in the aquarium. Of the two methods hitherto in use, that of pumping a jet of air into tanks otherwise stagnant or nearly so (Brighton), while supplying sufficient oxygen, has so many other disadvantages, that it has not been employed regularly in any of the more modern aquaria. It is, however, still useful in aerating quite small bodies of water in which hardy and minute organisms can be isolated and kept under control. In the other method, now in general use, a fine jet of water under pressure falls on to the surface of the tank; this carries down with it a more than sufficient air-supply, analysis showing in some cases a higher percentage of oxygen in aquarium water than in the open sea.

This water supply is best effected by gravity from reservoirs placed above the tanks, but may be also achieved by direct pumping from low reservoirs, or from the sea to the tanks. Provided that an unlimited supply of pure water can be obtained cheaply, the overflow from the tanks is best run to waste; but in aquaria less fortunately placed, it returns to a storage low-level reservoir, from which it is again pumped, thus circulating round and round (Naples, Plymouth). The storage reservoirs should be in all cases very large in comparison with the bulk of water in circulation; if practicable, they should be excavated in rock, and lined with the best cement. There is no reason why they should not be shallow, exposed to light and air, and cultivated as rock-pools by the introduction of sea-weeds and small animals, but they must then be screened from rain, cold, and dust. The pumps used in circulation will be less likely to kill minute animals if of the plunger or ram type, rather than rotary, and should be of gun-metal or one of the new bronze-alloys which take a patina in salt water. For the circulating pipes many materials have been tried. Vulcanite is not only expensive and brittle, but has other disadvantages; common iron pipes, coated internally with cement or asphalt, or glazed internally, with all unions and joints cemented, have been used with more or less success. Probably best of all is common lead piping, the joints being served with red-lead; water should be circulated through such pipes till they become coated with insoluble carbonate, for some time before animals are put into the tanks. For small installations glass may be used, the joints being made with marine glue or other suitable cement.

In building the tanks themselves, regard must be had to their special purposes. If intended for show-tanks for popular admiration, or for the study of large animals, they must be large with a plate-glass front; for ordinary scientific work small tanks with all sides opaque are preferable from every point of view. According to their character, size, and position, fixed tanks may be of brick-work, masonry, or rock, coated in each case with cement;

asphalting the sides offers no particular advantages, and often gives rise to great trouble and expense. All materials, and especially the cements, must be of the finest quality procurable. For smaller and movable tanks, slate slabs bolted or screwed together have some disadvantages, notably those of expense, weight, and brittleness, but are often used. Better, cheaper, and lighter, if less permanent, are tanks of wood bolted together, pitched internally. Glass bell-jars, useful in particular cases, should generally have their sides darkened, except when required for observation. Provision should always be made for cleaning every part of the tanks, pipes, and reservoirs; all rock-work in tanks should therefore be removable. As regards the lighting of fixed tanks, it should always be directly from above. In all tanks with glass sides, whether large or small, as much light as possible should be kept from entering through the glass; otherwise, with a side-light, many animals become restless, and wear themselves out against the glass, affected by even so little light as comes through an opposite tank.

In cases where distance from the sea or other causes make it impracticable to allow the overflow from the tanks to run to waste, special precautions must be taken to keep the water pure. Chemically speaking, the chief character of the water in an aquarium circulation, when compared with that of the open sea, lies in the excessive quantity of nitrogen present in various forms, and the reduced alkalinity; these two being probably connected. The excess of nitrogen is referable to dead animals, to waste food, and to the excreta of the living organisms. The first two of these sources of contamination may be reduced by care and cleanliness, and by the maintenance of a flow of water sufficient to prevent the excessive accumulation of sediment in the tanks. The following experiment shows the rapid rise of nitrogen if unchecked. A tank with a considerable fauna was isolated from the general circulation and aerated by four air-jets, except during hours 124-166 of the experiment; column I. shows per 100,000 the nitrogen estimated as ammonia, column II. the total inorganic nitrogen:—

	I.	II.
Sea water at source of original supply	0·001	0·008

" 141 " 	0·015	2·200
" 165 " 	0·025	...
" 169 " 	0·025	...
" 189 " 	0·012	...

During this time the alkalinity was reduced to the equivalent of 30 mg. CaCO₃ per litre, ocean water having an alkalinity equivalent to 50-55 mg. per litre. It has been suggested that the organic nitrogen becomes oxidized into nitrous, then into nitric acid, which lowers the carbonate values. A great deal of reduction of this nitrogenous contamination can be effected by filtration, a method first introduced successfully at Hamburg, where a most thriving aquarium has been maintained by the local Zoological Society for many years on the circulation principle, new water being added only to compensate for waste and evaporation. The filters consist of open double boxes, the inner having a bottom of perforated slate on which rests rough gravel; on the latter is fine gravel, then coarse, and finally fine sand. Filtration may be either upwards or downwards through the inner box to the outer. Such filters, intercalated between tanks and reservoir, have been shown by analysis to stop a very large proportion of nitrogenous matter. It is doubtful whether aquarium

water will not always show an excess of nitrogenous compounds, but they must be kept down in every way possible. In small tanks, well lighted, sea-weeds can be got to flourish in a way that has not been found practicable in large tanks with a circulation; these, with Lamelli-branches and small Crustacea as scavengers, will be found useful in this connexion. Slight or occasional circulation should be employed here also, to remove the film of dust and other matters, which otherwise covers the surface of the water and prevents due oxygenation.

In such small tanks for domestic use the fauna must be practically limited to bottom-living animals, but for purposes of research it is often desired to keep alive larval and other surface-swimming animals (plankton). In this case a further difficulty is presented, that of helping to suspend the animals in the water, and thus to avoid the exhaustion and death which soon follow their unaided efforts to keep off the bottom; this duty is effected in nature by specific gravity, tide, and surface current. In order to deal with this difficulty a simple but efficient apparatus has been devised by Mr E. T. Browne; a "plunger," generally a glass plate or filter funnel, moves slowly up and down in a bell-jar or other small tank, with a period of rest between each stroke; the motive power is obtained through a simple bucket-and-siphon arrangement worked by the overflow from other tanks. This apparatus (first used at the Plymouth Laboratory of the Marine Biological Association in 1897, and since introduced into similar institutions), by causing slight eddies in the water, keeps the floating fauna in suspension, and has proved very successful in rearing larvæ and in similar work. (G. H. Fo.)

Aqueduct.—The term aqueduct, although properly including artificial works of every kind by means of which water is conveyed from one place to another, is generally used in a more limited sense. It is, in fact, rarely employed except in cases where the work is of considerable magnitude and importance, and where the water flows naturally by gravitation.

The most important purpose for which aqueducts are constructed is that of conveying pure water, from sources more or less distant, to large masses of population. Where towns are favourably situated the aqueduct may be very short and its cost bear a relatively small proportion to the total outlay upon a scheme of water supply, but where distant sources have to be relied upon the cost of the aqueduct becomes one of the most important features in the scheme, and the quantity of water obtainable must be considerable to justify the outlay. Hence it is that only very large towns can undertake the responsibility for this expenditure, though, either voluntarily on the part of the promoters, or by the action of Parliament, smaller sanitary districts near the aqueduct are allowed to become customers for the water. In Great Britain it has, in fact, in all large schemes become a condition that, when a town is permitted to go outside its own watershed, it shall, subject to a priority of a certain number of gallons per day per head of its own inhabitants, allow local authorities, any part of whose district is within a certain number of miles of the aqueduct, to take a supply on reasonable terms. The first case in which this principle was adopted on a large scale was the Thirlmere scheme, sanctioned by Parliament in 1879, for augmenting the supply of Manchester. The previous supply was derived from a source only about 15 miles distant, and the cost of the aqueduct, chiefly cast-iron pipes, was insignificant compared with the cost of the impounding reservoirs. But Thirlmere is 96 miles distant from the service reservoir near Manchester, and the cost of the aqueduct was more than

90 per cent. of the total cost. As a supply of about 50,000,000 gallons a day is available the outlay was justifiable, and the water is in fact very cheaply obtained. Liverpool derives a supply of about 40,000,000 gallons a day from the river Vyrnwy in North Wales, 68 miles distant, and Birmingham is constructing works for impounding water in Radnorshire, and conveying it a distance of 74 miles, the supply being about 75,000,000 gallons a day. In the year 1899 an Act of Parliament was passed authorizing the towns of Derby, Leicester, Sheffield, and Nottingham, jointly to obtain a supply of water from the head waters of the river Derwent in Derbyshire. Leicester is 60 miles distant from this source, and its share of the supply is about 10,000,000 gallons a day. For more than half the distance, however, the aqueduct is common to Derby and Nottingham, which together are entitled to about 16,000,000 gallons a day, and the expense to Leicester is correspondingly reduced. These are the most important cases of long aqueducts in England, and all are subsequent to 1879. It is obvious, therefore, how greatly the design and construction of the aqueduct have grown in importance, and what care must be exercised in order that the supply upon which such large populations depend may not be interrupted, and that the country through which such large volumes of water are conveyed may not be flooded in consequence of the failure of any of the works.

Practically only two types of aqueduct are used in England. The one is built of concrete, brickwork, &c., the other of cast-iron (or, in special circumstances, steel) pipes. In the former type the water surface coincides with the hydraulic gradient, and the conditions are those of an artificial river; the aqueduct must therefore be carefully graded throughout, so that the fall available between source and termination may be economically distributed. This condition requires that the ground in which the work is built shall be at the proper elevation; if at any point this is not the case, the aqueduct must be carried on a substructure built up to the required level. Such large structures are, however, extremely expensive, and require elaborate devices for maintaining watertightness against the expansion and contraction of the masonry due to changes of temperature. They are now only used where their length is very short, as in cases where mountain streams have to be crossed, and even these short lengths are avoided by some engineers, who arrange that the aqueduct shall pass, wherever practicable, under the streams. Where wide valleys interrupt the course of the built aqueduct, or where the absence of high ground prevents the adoption of that type at any part of the route, the cast-iron pipes hereafter referred to are used.

The built aqueduct may be either in tunnel, or cut-and-cover, the latter term denoting the process of cutting the trench, building the floor, side-walls, and roof, and covering with earth, the surface of the ground being restored as before. For works conveying water for domestic supply, the aqueduct is in these days, in England, always covered. Where, as is usually the case, the water is derived from a tract of mountainous country, the tunnel work is sometimes very heavy. In the case of the Thirlmere aqueduct, out of the first 13 miles the length of the tunnelled portions is 8 miles, the longest tunnel being 3 miles in length. Conditions of time, and the character of the rock, usually require the use of machinery for driving, at any rate in the case of the longer tunnels. For the comparatively small tunnels required for aqueducts, two percussion drilling machines are usually mounted on a carriage, the motive power being derived from compressed air sent up the tunnel in pipes. The holes when driven are charged with

explosives and fired. In the Thirlmere tunnels, driven through very hard Lower Silurian strata, the progress was about 13 yards a week at each face, work being carried on continuously day and night for six days a week. Where the character of the country through which the aqueduct passes is much the same as that from which the supply is derived, the tunnels need not be lined with concrete, &c., more than is absolutely necessary for retaining the water and supporting weak places in the rock; the floor, however, is nearly always so treated. The lining, whether in tunnel or cut-and-cover, may be either of concrete, or brickwork, or of concrete faced with brickwork. To ensure the impermeability of work constructed with these materials is in practice somewhat difficult, and no matter how much care is taken by those supervising the workmen, and even by the workmen themselves, it is impossible to guarantee entire freedom from trouble in this respect. With a wall only about 15 inches thick, any neglect is certain to make the work permeable; frequently the labourers do not distribute the broken stone and fine material of the concrete uniformly, and no matter how excellent the design, the quality of materials, &c., a leak is sure to occur at such places (unless, indeed, the pressure of the outside water is superior and an inflow occurs). A further cause of trouble lies in the water which flows from the strata on to the concrete, and washes away some of the cement upon which the work depends for its watertightness, before it has time to set. For this reason it is advisable to put in the floor before, and not after, the side-walls and arch have been built, otherwise the only outlet for the water in the strata is through the ground on which the floor has to be laid. Each length of about 20 feet should be completely constructed before the next is begun, the water then having an easy exit at the leading end. Manholes, by which the aqueduct can be entered, are usually placed in the roof at convenient intervals; thus, in the case of the Thirlmere aqueduct, they occur at every quarter of a mile.

In some parts of America aqueducts are frequently constructed of wood, being then termed flumes. These are probably more extensively used in California than in any other part of the world, for conveying large quantities of water which is required for hydraulic mining, for irrigation, for the supply of towns, and for transporting timber. The flumes are frequently carried along precipitous mountain slopes, and across valleys, supported on trestles. In Fresno county, California, there is a flume 52 miles in length for transporting timber from the Sierra Nevada Mountains to the plain below; it has a rectangular V-shaped section, 3 feet 7 inches wide at the top, and 21 inches deep vertically. The boards which form the sides are 1½ inches thick, and some of the trestlework is 130 feet high. The steepest grade occurs where there is a fall of 730 feet in a length of 3000 feet. About 9,000,000 feet of timber were used in the construction. At San Diego there is a flume 35 miles long for irrigation and domestic supply, the capacity being 50 feet per second; it has 315 trestle bridges (the longest of which is that across Los Coches Creek, 1794 feet in length and 65 feet in height) and 8 tunnels; and the cost was \$900,000. The great bench flume of the Highline canal, Colorado, is 2640 feet in length, 28 feet wide, and 7 feet deep; the gradient is 5.28 feet per mile, and the discharge 1184 feet per second.

As previously stated, the type of aqueduct built of concrete, &c., can only be adopted where the ground is sufficiently elevated to carry it, and where the quantity of water to be conveyed makes it more economical than piping. Where the falling contour is interrupted by valleys too wide for a masonry structure above the surface of the

Construction.

ground, the detached portions of the built aqueduct must be connected by rows of pipes laid beneath, and following the main undulations of, the surface. In such cases the built aqueduct terminates in a chamber of sufficient size to enclose the mouths of the several pipes, which, thus charged, carry the water under the valley up to a corresponding chamber on the further hillside, from which the built aqueduct again carries on the supply. These connecting pipes are sometimes called siphons, although they have nothing whatever to do with the principle of a siphon, the water simply flowing into the pipe at one end and out at the other under the influence of gravity, and the pressure of the atmosphere being no element in the case. The pipes are almost always made of cast-iron, except in such cases as the lower part of some siphons, where the pressure is very great, or where they are for use abroad, when considerations of weight are of importance, and when they are made of rolled steel with riveted or welded seams. It is frequently necessary to lay them in deep cuttings, in which case cast-iron is much better adapted for sustaining a heavy weight of earth than the thinner steel, though the latter is more adapted to resist internal pressure. Mr D. Clarke in the *Trans. Am. Soc. C. E.* vol. xxxviii. p. 93, gives some particulars of a riveted steel pipe 24 miles long, 33 to 42 inches' diameter, varying in thickness from 0.22 inch to 0.375 inch. After a length of 9 miles had been laid, and the trench refilled, it was found that the crown of the pipe had been flattened by an amount varying from $\frac{1}{2}$ inch to 4 inches. Steel pipes suffer more from corrosion than those made of cast-iron, and as the metal attacked is much thinner the strength is more seriously reduced. These considerations have prevented any general change from cast-iron to steel.

Mr Clemens Herschell has made some interesting remarks (*Proc. Inst. C. E.* vol. cxv. p. 162) as to the circumstances in which steel pipes have been found preferable to cast-iron. He says that it had been demonstrated by practice that cast-iron cannot compete with wrought-iron or steel pipes in the States west of the Rocky Mountains, on the Pacific slope. This is due to the absence of coal and iron ore in these States, and to the weight of the imported cast-iron pipes compared with steel pipes of equal capacity and strength. The works of the East Jersey Water Company for the supply of Newark, N.J., include a riveted steel conduit 48 inches in diameter and 21 miles long. This conduit is designed to resist only the pressure due to the hydraulic gradient, in contradistinction to that which would be due to the hydrostatic head, this arrangement saving 40 per cent. in the weight and cost of the pipes. For the supply of Rochester, N.Y., there is a riveted steel conduit 36 inches in diameter and 20 miles long; and for Allegheny City, Pennsylvania, there is a steel conduit 5 feet in diameter and nearly 10 miles long. The works for bringing the water from La Vigne and Verneuil to Paris, include a steel main 5 feet in diameter between St Cloud and Paris.

Cast-iron pipes rarely exceed 48 inches in diameter, and even this diameter is only practicable where the pressure of the water is low. In the Thirlmere aqueduct the greatest pressure is nearly 180 lb on the square inch, the pipes where this occurs being 40 inches in diameter and 1 $\frac{1}{2}$ inches thick. These large pipes, which are usually made in lengths of 12 feet, are generally cast with a socket at one end for receiving the spigot end of the next pipe, the annular space being run with lead, which is prevented from flowing into the interior of the pipe by a spring ring subsequently removed; the surface of the lead is then caulked all round the outside of the pipe. A wrought-iron ring is sometimes shrunk on the outer rim of the socket, previously turned to receive it, in order to strengthen it against the wedging action of the caulking tool. Sometimes the pipes are cast as plain tubes and joined with double collars, which are run with lead as in the last case. The reason for adopting the latter type is that the stresses set up in the thicker metal of the socket by unequal cooling are thereby avoided, a very usual place for pipes to crack under pressure being at the back of the socket. The method of turning and boring a portion, slightly tapered, of spigot and socket so as to ensure a watertight junction by close annular metallic contact, is not suitable for large pipes, though very convenient for smaller diameters in even ground. Spherical joints are sometimes used where a line of main has to be laid under a large river or estuary, and where, therefore, the pipes

must be jointed before being lowered into the previously dredged trench. This was the case at the Willamette river, Portland, Oregon, where a length of 2000 feet was required. The pipes are of cast-iron 28 inches in diameter, 1 $\frac{1}{4}$ inches thick, and 17 feet long. The spigots were turned to a spherical surface of 20 inches' radius outside, the inside of the sockets being of a radius $\frac{1}{8}$ inch greater. After the insertion of the spigot into the socket, a ring, 3 inches deep, turned inside to correspond with the socket, was bolted to the latter, the annular space then being run with lead. These pipes were laid on an inclined cradle, one end of which rested on the bed of the river and the other on a barge where the jointing was done; as the pipes were jointed the barge was carefully advanced, thus trailing the pipes into the trench (*Trans. Am. Soc. C. E.* vol. xxxiii. p. 257). As may be conjectured from the pressure which they have to stand, very great care has to be taken in the manufacture and handling of cast-iron pipes of large diameter, a care which must be unflinching from the time of casting until they are jointed in their final position in the ground. They are cast vertically, socket downwards, so that the densest metal may be at the weakest part, and it is advisable to allow an extra head of metal of about 12 inches, which is subsequently cut off in a lathe. An inspector representing the purchaser watches every detail of the manufacture, and if, after being measured in every part and weighed, they are found satisfactory they are proved with internal fluid pressure, oil being preferable to water for this purpose. While under pressure, they are rapped from end to end with a hand hammer of about 5 lb in weight, in order to discover defects. The wrought-iron rings are then, if required, shrunk on to the sockets, and the pipes, after being made hot in a stove, are dipped vertically in a composition of pitch and oil, in order to preserve them from corrosion. All these operations are performed under cover. A record should be kept of the history of the pipe from the time it is cast to the time it is laid and jointed in the ground, giving the date, number, diameter, length, thickness, and proof pressure, with the name of the pipe-jointer whose work closes the record. Such a history sometimes enables the cause (which is often very obscure) of a burst in a pipe to be ascertained, the position of every pipe being recorded.

Cast-iron pipes, even when dipped in the composition referred to, suffer considerably from corrosion caused by the water, especially soft water, flowing through them: One pipe may be found in as good a condition as when made, while the next may be covered with nodules of rust. The effect of the rust is twofold: it reduces the area of the pipe, and also, in consequence of the resistance offered by the rough surface, retards the velocity of the water. These two results, especially the latter, may seriously diminish the capability of discharge, and they should always be allowed for in deciding the diameter. Automatic scrapers are sometimes used with good results, but it is better to be independent of them as long as possible. In one case the discharge of pipes, 40 inches in diameter, was found to diminish at the rate of about 1 per cent. per year; in another case, where the water was soft and where the pipes were 40 inches in diameter, the discharge was diminished by 7 per cent. in ten years. An account of the state of two cast-iron mains supplying Boston with water is given in the *Trans. Am. Soc. C. E.* vol. xxxv. p. 241. These pipes, which were laid in 1877, are 48 inches in diameter and 1800 feet long. When they were examined in 1894-95, it was estimated that the tubercles of rust covered nearly one-third of the interior surfaces, the bottom of the pipe being more incrustated than the sides and top. They had central points of attachment to the iron, at which no doubt the coating was defective, and from them the tubercles spread over the surface of the surrounding coating. In this case they were removed by hand, and the coating of the pipes was not injured in the process. Cast-iron pipes must not be laid in contact with cinders from a blast furnace with which roads are sometimes made, because these corrode the metal. Mr Russell Aitken (*Proc. Inst. C. E.* vol. cxv. p. 93) found in India that cast-iron pipes buried in the soil rapidly corroded, owing to the presence of nitric acid secreted by bacteria which attacked the iron. The large cast-iron pipes conveying the water from the Tansa reservoir to Bombay are laid above the surface of the ground. Cast-iron pipes of these large diameters have not been in existence sufficiently long to enable their life to be predicted. A main, 40 inches in diameter, conveying soft water, has been in existence fifty years at Manchester, and is apparently as good as ever. In 1867 Mr J. B. Francis found that no apparent deterioration had taken place in a cast-iron main, 8 inches' diameter, which was laid in the year 1828, a period of thirty-nine years (*Trans. Am. Soc. C. E.* vol. i. p. 26). These two instances are probably not exceptional.

Pipes in England are usually laid with not less than 2 feet 6 inches of cover, in order that the water may not be frozen in a severe winter. Where they are laid in deep cutting they should be partly surrounded with concrete, so that they may not be fractured by the weight of

earth above them. Angles are turned by means of special bend pipes, the curves being made of as large a radius as convenient. In the case of the Thirlmere aqueduct, double socketed castings about 12 inches long (exclusive of the sockets) were used, the sockets being inclined to each other at the required angle. They were made to various angles, and for any particular curve several would be used connected by straight pipes 3 feet long. As special castings are nearly double the price of the regular pipes, the cost was much diminished by making them as short as possible, while a curve, made up of the slight angles used, offered practically no more impediment to the flow of water in consequence of its polygonal form, than would be the case had special bend pipes been used. In all cases of curves on a line of pipes under internal fluid pressure, there exists a resultant force tending to displace the pipes. When the curve is in a horizontal plane and the pipes are buried in the ground, the side of the pipe trench offers sufficient resistance to this force. Where, however, the pipes are above ground, or when the curve is in a vertical plane, it is necessary to anchor them in position. In the case of the Tansa aqueduct to Bombay, there is a curve of 500 feet radius near Bassein Creek. At this point the hydrostatic head is about 250 feet, and the engineer, Mr Clerke, mentions that a tendency to an outward movement of the line of pipes was observed. At the siphon under Kurla Creek the curves on the approaches as originally laid down were sharp, the hydrostatic head being there about 210 feet; here the outward movement was so marked that it was considered advisable to realign the approaches with easier curves (*Proc. Inst. C. E.* vol. cxv. p. 34). In the case of the Thirlmere aqueduct the greatest hydrostatic pressure, 410 feet, occurs at the bridge over the river Lune, where the pipes are 40 inches in diameter, and in descending from the bridge make reverse angles of $31\frac{1}{2}^{\circ}$. The displacing force at each of these angles amounts to 54 tons, and as the design includes five lines of pipes, it is obvious that the anchoring arrangements must be very efficient. The steel straps used for anchoring these and all other bends were curved to fit as closely as possible the castings to be anchored. Naturally the metal was not in perfect contact, but when the pipes were charged the disappearance of all the slight inequalities showed that the straps were fulfilling their intended purpose. At every summit on a line of pipes one or more valves must be placed in order to allow the escape of air, and they must also be provided on long level stretches, and at changes of gradient where the depth of the point of change below the hydraulic gradient is less than that at both sides, causing what may be called a virtual summit. It is better to have too many than too few, as accumulations of air may cause an enormous diminution in the quantity of water delivered. In all depressions discharge valves should be placed for emptying the pipes when desired, and for letting off the sediment which accumulates at such points. Automatic valves are frequently placed at suitable distances for cutting off the supply in case of a burst. At the inlet mouth of the pipe they may depend for their action on the sudden lowering of the water (due to a burst in the pipe) in the chamber from which they draw their supply, causing a float to sink and set the closing arrangement in motion. Those on the line of main are started by the increased velocity in the water, caused by a burst on the pipe at a lower level. The water, when thus accelerated, is able to move a disc hung in the pipe at the end of a lever and weighted so as to resist the normal velocity; this lever releases a catch, and a door is then gradually revolved by weights until it entirely closes the pipe. Reflux valves on the ascending leg of a siphon prevent water from flowing back in case

of a burst below them; they have doors hung on hinges, opening only in the normal direction of flow. Due allowance must be made, in the amount of head allotted to a pipe, for any head which may be absorbed by such mechanical arrangements as those described where they offer opposition to the flow of the water. These large mains require most careful and gradual filling with water, and constant attention must be given to the air-valves to see that the gutta-percha balls do not wedge themselves in the openings. A large mass of water, having a considerable velocity, may cause a great many bursts by water-ramming, due to the admission of the water at too great a speed. In places where iron is absent and timber plentiful, as in some parts of America, pipes, even of large diameter and in the most important cases, are sometimes made of wooden staves hooped with iron. A description of two of these will be found below.

The *Thirlmere Aqueduct*, to which reference has been made above, is capable of conveying 50,000,000 gallons a day from Thirlmere, in the English lake district, to Manchester. The total length of 96 miles is made up of 14 miles of tunnels, 37 miles of cut-and-cover, and 45 miles of cast-iron pipes, five rows of the latter being required. The tunnels where lined, and the cut-and-cover, are formed of concrete, and are 7 feet in height and width, the usual thickness of the concrete being 15 inches. The inclination is 20 inches per mile. The floor is flat from side to side, and the side-walls are 5 feet high to the springing of the arch, which has a rise of 2 feet. The water from the lake is received in a circular well 65 feet deep and 40 feet in diameter, at the bottom of which there is a ring of wire-gauze strainers. Wherever the concrete aqueduct is intersected by valleys, cast-iron pipes are laid; at present only one of the five rows 40 inches in diameter has been laid, as the city does not yet require its present supply to be augmented by more than 10,000,000 gallons a day. All the elaborate arrangements described above for stopping the water in case of a burst have been employed, and have perfectly fulfilled their duties in the few cases in which they have been called into action. The water is received in a service reservoir at Prestwich, near Manchester, from which it is supplied to the city. The supply from this source was begun in 1894. The total cost of the complete scheme will not be far short of £5,000,000, of which rather under £3,000,000 had been spent up to the date of the opening.

The *Vyrnwy Aqueduct* was sanctioned by parliament in 1880 for the supply of Liverpool from North Wales, the quantity of water obtainable being at least 40,000,000 gallons a day. A tower built in the artificial lake from which the supply is derived, contains the inlet and arrangements for straining the water. The aqueduct is 68 miles in length, and for nearly the whole distance will consist of three lines of cast-iron pipes, one of which, varying in diameter from 42 inches to 39 inches, is now in use. As the total fall between Vyrnwy and the termination at Prescott reservoirs is about 550 feet, arrangements had to be made to ensure that no part of the aqueduct be subjected to a greater pressure than is required for the actual discharge. Balancing reservoirs have therefore been constructed at five points on the line, advantage being taken of high ground where available, so that the total pressure is broken up into sections. At one of these points, where the ground level is 110 feet below the hydraulic gradient, a circular tower is built, making a most imposing architectural feature in the landscape. At the crossing of the river Weaver, 100 feet wide and 15 feet deep, the three pipes, here made of steel, were connected together laterally, floated into position, and sunk into a dredged trench prepared to receive them. Under the river Mersey the pipes are carried in a tunnel, from which, during construction, the water was excluded by compressed air.

Denver Aqueduct.—The new supply to Denver City, initiated by the Citizens Water Company in 1889, is derived from the Platte river, rising in the Rocky Mountains. The first aqueduct constructed is rather over 20 miles in length, of which a length of $16\frac{1}{2}$ miles is made of wooden stave pipe, 30 inches in diameter. The maximum pressure is that due to 185 feet of water; the average cost of the wooden pipe was \$1.36½ per foot, and the capability of discharge 8,400,000 gallons a day. Within a year of the completion of the first conduit, it became evident that another of still greater capacity was required. This was completed in April 1893; it is 34 inches in diameter and will deliver 16,000,000 gallons a day. By increasing the head upon the first pipe, the combined discharge is 30,000,000 gallons a day. An incident in obtaining a temporary supply, without waiting for the completion of the second pipe, was the construction of two wooden pipes, 13

inches in diameter, crossing a stream with a span of 104 feet, and having no support other than that derived from their arched form. One end of the arch is 24½ feet above the other end, and, when filled with water, the deflection with eight men on it was only ¼ of an inch. A somewhat similar arch, 60 feet span, occurs on the 34-inch pipe where it crosses a canal. Mr Schuyler points out (*Trans. Am. Soc. C. E.* vol. xxxi, p. 148) that the fact that the entire water supply of a city of 150,000 inhabitants is conveyed in wooden mains, is so radical a departure from all precedents, that it is deserving of more than a passing notice. He says that it is manifestly and unreservedly successful, and has achieved an enormous saving in cost. The sum saved by the use of wooden, in preference to cast-iron pipes, is estimated at \$1,100,000. It is perhaps necessary to state that the pipe is buried in the ground in the same way as metal pipes. The edges of the staves are dressed to the radius with a minute tongue ¼ inch high on one edge of each stave, but with no corresponding groove in the next stave; its object is to ensure a close joint when the bands are tightened up. Leaks seldom or never occur along the longitudinal seams, but the end shrinkage caused troublesome joint leaks. The shrinkage in California redwood, which had seasoned 60 to 90 days before milling, was frequently as much as 3 inches in the 20 staves that formed the 34-inch pipe, and the space so formed had to be filled by a special closing stave. Metallic tongues, ¼ inch deep, are inserted at the ends of abutting staves, in a straight saw cut. The bands, which are of mild steel, have a head at one end and a nut and washer at the other; the ends are brought together on a wrought-iron shoe, against which the nut and washer set. The staves forming the lower half of the pipe are placed on an outside, and the top staves on an inside, mould. While the bands are being adjusted the pipe is rounded out to bring the staves out full, and the staves are carefully driven home on to the abutting staves. The spacing of the bands depends on circumstances, but is about 150 bands per 100 feet. With low heads the limit of spacing was fixed at 17 inches. The outer surface of the pipe, when charged, shows moisture oozing slightly over the entire surface. This condition Mr Schuyler considers an ideal one for perfect preservation, and the staves were kept as thin as possible to ensure its occurrence. Samples taken from pipes in use from three to nine years are quite sound, and it is concluded that the wood will last as long as cast-iron if the pipe is kept constantly charged. The bands are the only perishable portion, and their life is taken at from fifteen to twenty years. Other portions of the second conduit for a length of nearly 3 miles were formed of concrete piping, 38 inches' diameter, formed on a mould in the trench, the thickness being 2½ to 3 inches. So successful an instance of the use of wooden piping on a large scale, is sure to lead to a large development of this type of aqueduct in districts where timber is plentiful and iron absent.

Pioneer Aqueduct, Utah.—The construction of the Pioneer Aqueduct, Utah, was begun in 1896 by the Pioneer Electric Power Company, near the city of Ogden, 35 miles north of Salt Lake City. The storage reservoir, from which it draws its water, will cover an area of 2000 acres, and contain about 15,000 million gallons of water. The aqueduct is a pipe 6 feet in diameter, and of a total length of 6 miles; for a distance of rather more than 5 miles it is formed of wooden staves, the remainder, where the head exceeds 117 feet, being of steel. It is laid in a trench and covered to a depth of 3 feet. The greatest pressure on the steel pipe is 200 lb per square inch, and the thickness varies from ¾ to 1½ inch. The pipe was constructed according to the usual practice of marine boiler-work for high pressures, and each section, about 9 feet long, was dipped in asphalt for an hour. These sections were supported on timber blocking, placed from 5 to 9 feet apart, and consisting of three to six pieces of 6×6 inch timbers laid one on the top of the other; they were then riveted together in the ordinary way. The wooden stave-pipe is of the type successfully used in the Western States for many years, but its diameter is believed to be unequalled for any but short lengths. There were thirty-two staves in the circle, 2 inches in thickness, and about 20 feet long, hooped with round steel rods ½ inch in diameter, each hoop being in two pieces. The pipe is supported at intervals of 8 feet by sills 6×8 inches and 8 feet long. The flow through it is 250 cubic feet per second.

The **Santa Ana Canal** was constructed for irrigation purposes in California, and is designed to carry 240 cubic feet of water per second (*Trans. Am. Soc. C. E.* vol. xxxiii, p. 99). The cross section of the flumes shows an elliptical bottom and straight sides consisting of wooden staves held together by iron and steel ribs. The width and depth are each 5 feet 6 inches, the intended depth of water being 5 feet. The staves are held by T-iron supports resting on wooden sills spaced 8 feet apart, and are compressed together by a framework. They were caulked with oakum, on the top of which, to a third of the total depth, hot asphalt was run. The use of nails was altogether avoided except in parts of the framework, it being noticed that decay usually

starts at nail holes. It was found possible to make the flume absolutely watertight, and in case of repair being necessary at any part the framework is easily taken to pieces so that new staves can be inserted. The water in the flume has a velocity of 9·6 feet per second. The Warm Springs, Deep, and Morton, cañons on the line are crossed by wooden stave pipes 52 inches in diameter, bound with round steel rods, and laid above the surface of the ground. The work is planned for two rows of pipes, each capable of carrying 123 cubic feet per second; of these one so far has been laid. The lengths of the pipes at each of the three cañons are 551, 964, and 756 feet respectively, and the maximum head at any place is 160 feet. The pipes are not painted, and it has been suggested that they would suffer in their exposed position in case of a bush fire, a contingency to which, of course, flumes are also liable.

Aqueducts of New York.—There are three aqueducts in New York—the Old Croton Aqueduct (1837-43), the Bronx River Conduit (1880-85), and the New Croton Aqueduct (1884-93), discharging respectively 95, 28, and 302 million U.S. gallons a day; their combined delivery is therefore 425 million gallons a day. The Old Croton Aqueduct is about 41 miles in length, and was constructed as a masonry conduit, except at the Harlem and Manhattan valleys, where two lines of 36-inch pipe were used. The inclination of the former is at the rate of about 13 inches per mile. The area of the cross-section is 53·34 square feet, the height is 8½ feet, and the greatest width 7 feet 5 inches; the roof is semi-circular, the floor segmental, and the sides have a batter on the face of ¼ inch per foot. The sides and invert are of concrete, faced with 4 inches of brickwork, the roof being entirely of brickwork. There is a bridge over the Harlem river 1450 feet in length, consisting of fifteen semicircular arches; its soffit is 100 feet above high water, and its cost was \$963,427. The construction of the New Croton Aqueduct was begun in 1885, and the works were sufficiently advanced by 15th July 1890 to allow the supply to be begun. The lengths of the various parts of the aqueduct are as follows:—

	Miles.
Tunnel	29·75
Cut-and-cover	1·12
Cast-iron pipes, 48 inches diameter, 8 rows	2·38
	—
Croton Inlet to Central Park	33·25

The length of the tunnel under pressure (circular form) is 7·17 miles, and that not under pressure (horse-shoe form) 23·70 miles. The maximum pressure in the former is 55 lb per square inch. The width and height of the horse-shoe form are each 13 feet 7 inches, and the diameter of the circular form (with the exception of two short lengths) is 12 feet 3 inches. The reason for constructing the aqueduct in tunnel for so long a distance was the enhanced value of the low-lying ground near the old aqueduct. The tunnel deviates from a straight line only for the purpose of intersecting a few transverse valleys at which it could be emptied. For 25 miles the gradient is 0·7 foot per mile; the tunnel is then depressed below the hydraulic gradient, the maximum depth being at the Harlem river, where it is 300 feet below high water. The depth of the tunnel varies from 50 to 500 feet from the surface of the ground. Forty-two shafts were sunk to facilitate driving, and in four cases where the surface of the ground is below the hydraulic gradient these are closed by watertight covers. The whole of the tunnel is lined with brickwork from 1 to 2 feet in thickness, the voids behind the lining being filled with rubble-in-mortar. The entry to the old and new aqueducts is controlled by a gate-house of elaborate and massive design, and the pipes which take up the supply at the end of the tunnel are also commanded by a gate-house. The aqueduct, where it passes under the Harlem river, is worthy of special notice. As it approaches the river it has a considerable fall, and eventually ends in a vertical shaft 12 feet 3 inches in diameter (where the water has a fall of 174 feet), from the bottom of which, at a depth of 300 feet below high-water level, the tunnel under the river starts. The latter is circular in form, the diameter being 10 feet 6 inches, and the length is 1300 feet; it terminates at the bottom of another vertical shaft also 12 feet 3 inches in diameter. The depth of this shaft, measured from the floor of the lower tunnel to that of the upper tunnel leading away from it, is 321 feet; it is continued up to the surface of the ground, though closed by double watertight covers a little above the level of the upper tunnel. Adjoining this shaft is another shaft of equal diameter, by means of which the water can be pumped out, and there is also a communication with the river above high-water level, so that the higher parts can be emptied by gravitation. The cost of the Old Croton Aqueduct was \$11,500,000; that of the new aqueduct is not far short of \$20,000,000.

The **Nadrai Aqueduct Bridge**, opened at the end of 1889, is the largest structure of its kind in existence. It was built to carry the water of the Lower Ganges canal over the Kali Nadrai. Naddi, in connexion with the irrigation canals of the north-west provinces of India. In the year 1888-89 this canal

had 564 miles of main line, with 2050 miles of minor distributaries, and irrigated 519,022 acres of crops. The new bridge replaces one of much smaller size (five spans of 35 feet), which was completely destroyed by a high flood in July 1885. It gives the river a waterway of 21,000 square feet, and the canal a waterway of 1040 square feet, the latter representing a discharge of 4100 cubic feet per second. Its length is 1310 feet, and it is carried on fifteen arches having a span of 60 feet. The width between the faces of the arches is 149 feet. The foundations below the river-bed have a depth of 52 feet, and the total height of the structure is 88 feet. It cost 44½ lakhs of rupees, and occupied four years in building. The foundations consist of 268 circular brick cylinders, and the fifteen spans are arranged in three groups, divided by abutment piers; the latter are founded on a double row of 12-foot cylinders, and the intermediate piers on a single row of 20-foot cylinders, all the cylinders being hearted with hydraulic lime concrete filled in with skips. This aqueduct-bridge has a very fine appearance, owing to its massive proportions and design.

For an account of the New York aqueduct see the *Report of the Aqueduct Commissioners*, 1887-95, and *The Water Supply of the City of New York*, 1896, by WEGMANN. For accounts of other aqueducts, see the *Transactions of the Societies of Engineers in the different countries*, and the *Engineering Journals*. (E. P. H.*)

Aquila, a town and bishop's see of Italy (Abruzzi and Molise), capital of the province of Aquila, situated in the Central Apennines, at the S.W. foot of the knot of Gran Sasso d'Italia, 145 miles N.E. from Rome by rail. There are two picture galleries, one in the town hall, the other in the Dragonetti (formerly De Torres) Palace, and an industrial arts and sciences school. University classes are held here. Owing to its altitude (2366 ft.), it is a favourite summer resort of the Italians. Population of commune (1881), 18,426; (1901), 21,215; of province (1881), 353,027; (1901), 397,645.

Arabi Pasha (more correctly AHMAD 'ARĀBĪ, to which in later years he added the epithet *al-Misri*, "the Egyptian"), Egyptian soldier and revolutionary leader, was born in Lower Egypt in 1839, of a fellah family. Having entered the army as a conscript he was made an officer by Said Pasha in 1862, and was employed in the transport department in the Abyssinian campaign under

Ismail Pasha. A charge of peculation was made against him in connexion with this expedition and he was placed on half-pay. During this time he joined a secret society formed by Ali Roubi with the object of getting rid of Turkish officers from the Egyptian army. In 1878 he was employed by Ismail in fomenting a disturbance against the ministry of Nubar, Wilson, and De Blignières, and received in payment a wife from Ismail's harem and the command of a regiment. This increased his influence with the secret society, which, under the feeble government of Tewfik Pasha and the Dual Control, began to agitate against Europeans. A military demonstration on 8th September 1881, led by Arabi, forced the Khedive to increase the numbers and pay of the army, to substitute Cherif Pasha for Riaz Pasha as prime minister, and to convene an assembly of notables. Arabi became under-secretary for war at the beginning of 1882, but continued his intrigues. The Assembly of Notables claimed the right of voting the budget, and thus came into conflict with the foreign controllers who had been appointed to guard the interests of the bondholders in the management of the Egyptian finances. Cherif fell in February, and Arabi (created a pasha) became minister of war. Fortified by the honours bestowed on him by the sultan, Arabi, after a brief fall from office, acquired a dictatorial power that alarmed the British Government. His arming of the forts at Alexandria was held to constitute a menace to the fleet. On the refusal of France to co-operate, the British fleet bombarded the forts (11th July), and a British force, under Sir Garnet Wolseley, defeated Arabi on 13th September at Tel-el-Kebir. Arabi surrendered, and was tried (3rd December) for the crime of rebellion. In accordance with an understanding made with the British representative, Lord Dufferin, Arabi pleaded guilty, and the formal sentence of death was immediately commuted to one of banishment for life to Ceylon. After his exile had lasted for nearly twenty years, however, the Khedive, Abbas II., exercised his prerogative of mercy, and in May 1901 Arabi was permitted to return to Egypt.

A R A B I A.

DURING the last quarter of the 19th century several notable journeys were made through Northern, Central, and Southern Arabia which, although they have led to no essential modification of previous views regarding the general physiography of that country, have added considerably to our knowledge of its topographical detail. Very little systematic survey has been possible in a country so remote from the centres of scientific movement, and so hostile to foreign interference. The eastern coast has been connected with the Indian system of triangulation across the Strait of Hormuz; and from Aden a local topographical survey has been carried into the southern offshoots of the Yemen Mountains by officers of the Indian Survey, based on a triangulation which is independent of India. Amongst recent investigations the researches of Dr Walker in the Sinai Peninsula have thrown new light on the coral formations of the western coast, and have elucidated some interesting problems in connection with Arabian desert formations. According to this authority, the change in surface configuration of the desert sands of Northern Arabia is due to no change in climatic factors. It is governed by the same laws to-day as it was thousands of years ago. Sand formations are produced by the differences of temperature (50° to 80° F.), to which the surface rock is daily exposed. The rock is first broken up by these differences into small fragments which are polished

and rounded by the action of wind-blown sand. Granite, especially, disintegrates rapidly on account of the difference in the specific heat of its constituent parts. Then the wind action again separates the component parts and forms broad spaces in the desert, of which the sand particles may consist uniformly either of mica or of quartz. But as regards recent illustration of the conformation and geology of the Arabian continent generally, it is to the researches of Doughty and Blunt, between the years 1876 and 1878, and to those of Theodore Bent subsequently, that we are most indebted for fresh material from English sources.

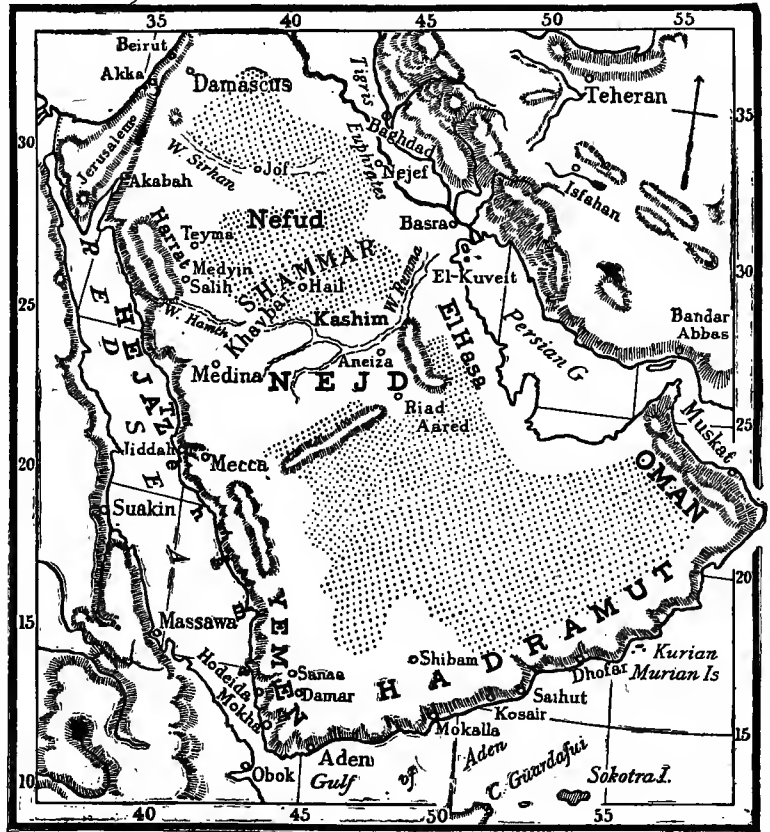

Doughty accompanied the annual pilgrimage, or "haj," from Damascus to Mecca, stopping at Medyin Salih (some 150 miles north-west of Medina) to copy Nabathæan inscriptions and explore the monuments of El Hajr. During the spring of 1877 he visited Nejd, returning again to El Hajr and exploring the cool and lofty Harrat during the summer. He afterwards journeyed northwards to Teyma, in the Nefud, and eastwards to Hail, the residence and capital of the Emir Ibn Rashid. From Hail he returned south-west to Khaybar, crossing an upland region of lava-fields and extinct volcanoes, which he believes to be the true water-parting between east and west in Northern Arabia. In the spring of 1878 he again returned to Nejd, visiting Aneyza and Boreyda, which he describes as its two most

important towns. Then recrossing the continent and traversing the elevated steppe which is the wandering ground of the great Beduin tribe, Ateyba, he finally reached Jidda, exhausted by the hardships and vicissitudes of his journey. It is worthy of note that he travelled openly as a Christian and an Englishman, and that he survived to write a standard work on Arabia; whilst Huber, who traversed much the same country in 1833-84, paid the penalty of the venture with his life. In 1878-79 Mr Wilfrid Blunt, accompanied by his intrepid wife, Lady Anne Blunt, travelled from Syria south-east to Jebel Shammar, skirting the great Wadi Sirhan depression to Jof, and thence crossing the Nefud. He thus followed a route approximately parallel to that of Doughty, at a distance of about 80 miles from it. On his return journey from Nejd he joined the bands of Persian pilgrims returning from Mecca, travelling nearly due north to Kerbela and Baghdad, passing through the country of the Daffir Beduins, so that between these two travellers we have a fairly connected account of the physiography of all Northern Arabia, differing in some important details from the earlier descriptions of Palgrave (ARABIA, *Ency. Brit.* ii. 235-265). Mr Bent, who was also accompanied by his wife, visited the Bahrein islands, on the east coast of Arabia, in 1888, and added much to our knowledge of this cradle of the Phœnician race. In 1893-94 he made an adventurous journey into the main valley of Hadramut, and later again visited the Southern Arabian coast, starting from Muskat, but was not successful in penetrating into the interior of the continent. Colonel S. B. Miles explored Oman and visited Dhofar, on the southern coasts of Arabia, in 1884. Yemen was traversed as late as 1892 by W. B. Harris, who travelled in disguise from Aden to Sanaa, the capital, where he was imprisoned by the Turkish authorities, and whence he was deported under an escort to Hodeida. In such circumstances he was not able to add much to the scientific information gained by previous travellers; but he gave an excellent descriptive account of the wonderful fertility and beauty of Arabia Felix. Stimulated by a journey of the French botanist Deflers in 1888, Dr Schweinfurth made a botanical exploration of Yemen in the winter of 1888-89, and Herr Eduard Glaser, about the same time, visited Mareb, the capital of the old Sabæan empire, and brought home with him numerous manuscripts. To the researches of these travellers in Northern, Central, Southern, and Western Arabia, we may add such matters of historical interest affecting Arabia as have been brought to light by the labours of the officers of the Indian Survey working in Baluchistan and Makrân. They undoubtedly open up a new chapter in Arabian commercial (if not military) history.

From Doughty we learn that the geology of Arabia is of truly Arabian simplicity. A central core of Plutonic rocks is overlaid by sandstones, and these again by limestones, sometimes accompanied with flints. This is a similar formation to that which appears again between the Dead Sea and Jerusalem, and probably underlies all Palestine. The "nefuds," or deep sandy deserts, are composed of material derived from the sandstones. The occurrence of volcanic rocks upon plateaux throughout Central Arabia was previously unrecorded,

Physiography.

but there appears to be a doubt whether the volcanic cones on the surface of the lava-flows of the "harrats" can geologically be connected with these flows. In the north-west the platform of sandstone which flanks the pilgrim route to Mecca from Damascus for about 150 miles, with its western edge approximately parallel to the Red Sea coast at a distance of about 100 miles, and which terminates southwards near El Hajr, is not the true watershed between the sand-plains of Teyma and the sea; for the drainage strikes across it from eastwards, and is possibly antecedent to the formation of the plateau. The surface of this great "harrat," or upland, which crowns the mountainous highlands of the coast, and is flanked on the east by a long extended depression, has been embedded by stream after stream of basaltic lava, and is studded with numerous extinct volcanoes. The highest of these volcanoes is estimated to be as much as 1000 feet above the plateau level. Between Shammar and Khaybar, striking south-west across the continent, the central districts consist of an upland space of lava-fields and extinct volcanoes (called "hilli-hillian" by the Arabs) rising to about 6000 feet above sea-level, forming another "harrat" known as the Harrat Khaybar. This was ascertained to be the

MAP OF ARABIA.

true water-parting of this part of the country; the waters flowing eastwards to the Wadi e' Rumma (which would be an affluent of the Euphrates if it were a perennial stream instead of a dry trough flushed once in a generation) and westwards to the Wadi el Humth (previously unknown) which has its mouth on the Red Sea coast.

Blunt describes the harrats or upland plains, closely adjoining the frontiers of Syria and Arabia to the south of Damascus, as a vast expanse of boulder-strewn desert, "a bleak and gloomy region across which it is difficult to travel with camels on account of the narrowness and intricacy of the paths which wind in and out amongst the boulders." From this region of black stones, extending south-eastwards for upwards of 300 miles to Jof, is the great depression of the Wadi Sirhan (probably an ancient arm of the sea) which is estimated to be less than 2000 feet above sea-level, and is flanked to the eastward by the vast gravelly plain of El Hamad on a higher level of 500 feet. Jof is a walled town of about 500 houses, which stands on the northern edge of the Nefud or red sand-plain of the interior. This plain extends for 200 miles to the foot of the Jebel Shammar, beneath which lies Hail, which Blunt places at the foot of the northern slopes to the

east of Jebel Aja, and Doughty shows to the south of that range. The rocky hills of the Nefud, like those of Jof, are of sandstone, varying in colour from yellow to red and purple, but weathered black on the upper surface. Jebel Shammar itself is composed of red granite. The general characteristics of these mountains and of their vegetation seem to be similar to those of Mount Sinai. The plain level at Hail is estimated by Blunt to be 4000 feet above sea-level, and the summits of the Shammar Mountains to be 2000 feet higher. The character of the Nefud plains apparently differs essentially from that described by Palgrave. The Nefud is now said to consist of a wide spread of coarse red sand, well clothed with shrubs, and after a rainy winter covered with grass and flowers. A few irregular low ridges exist in the Nefud, but they are not a prominent feature. On the other hand, the whole plain is pitted with deep hollows, shaped like a horse-shoe, with their points all set with great regularity towards the same point of the compass. These depressions are called by the Arabs "fulj," and vary in depth from 20 to 200 feet, and proportionately in width; the widest being about a quarter of a mile across. Another natural phenomenon which was previously described in considerable detail, but which Blunt found to be unsupported by local evidence, is the occurrence of the simoom, or poisonous wind, in these plains. Sandstorms are of frequent occurrence; but they are not poisonous. The deadly poison blast, which not merely suffocates by mechanical means, but which absolutely disseminates a poisonous vapour or gas, must be dissociated from the plains of the Nefud. The expression "nejd" is ascertained to be purely geographical, and in no sense political. In Arabia it is applied to all the high-level districts lying within the Nefuds. It includes the three provinces of Jebel Shammar, Kasim, and Aared. As employed by the Turks, the name is applied to their latest conquests on the seaboard of El Hasa, and so has led to a misapprehension as to the extent of Turkish sovereignty in Arabia. The plain of the Hamad, which Blunt crossed from Jebel Shammar to the borders of Arabia at Nejef, south of Babylon, has a uniform upward grade from the Sea of Nejef to Shammar. This slope is estimated to be about 10 feet per mile, and is not unbroken. It is due to "a series of shelves terminating in abrupt edges one above the other, the edges facing the line of descent." The Nefud of Eastern Arabia, as described by Sir Lewis Pelly, differs from the Nefud north of Shammar in some essential particulars. It consists of a series of huge sand ranges trending curvilinearly in a north-west and south-east direction, stretching roughly parallel to the Arab littoral of the Persian Gulf southwards from Jebel Shammar. Between the ridges are wide spaces of hard level plain, as much as from 7 to 8 miles in width. The central plateau commences to rise into Nejd proper from the district of Sedair. The route from the Persian Gulf westward, crossing this eastern Nefud, terminates at Riad (the Wahabi capital), 250 miles to the south-east of Hail.

Bent's expeditions to the south coast of Arabia and Hadramut geographically place these regions in an entirely new light.

Hadramut and Southern Arabia.

Hadramut is no longer to be regarded simply as a southern district of Arabia intervening between the sea coast and the central desert, but as a broad central artery running for a hundred miles or more parallel to the coast, through which the valleys of the high Arabian plateau discharge their scanty supplies of water to the sea near Saihut, towards which point the whole system gradually slopes. Into this hotbed of fanaticism but one European (Herr Leo Hirsch) had succeeded in penetrating before Bent, and he travelled in disguise. Theodore Bent and his wife travelled without disguise, and with a considerable train of followers. It seems to be clearly proved by the Himyaritic inscriptions found in the valley, that for five centuries B.C. the term Hadramut applied to this valley only, the meaning of it being the "Valley of Death." Here from time immemorial existed the historic trade in frankincense and myrrh, which centred in Shibam (a place of some importance even now), from whence the produce of the valley was conveyed westwards by the great frankincense road across Arabia of which an account is given to us by Claudius Ptolemæus.

The narrow coast-line of this part of Arabia is termed Sahil, and between Mokalla and Saihut it is described as a "most uncompromisingly arid country." Hot springs exist at intervals, pointing to the volcanic origin of the region, and where they are found they are utilized for the purposes of cultivation; but their occurrence is rare, and the coast generally is marked by an extended waste of barren sterility. Mokalla, Shehr, and Kosair are the chief coast towns. They carry on an active trade by means of their dhows and buggalows with Aden, Muskat, Bombay, and the Somali coast. A curious geological feature of the coast are the basalt fields near Kosair, which spread across the flat country in a stratum of black rock-like lava. The Arabs attribute this basaltic effusion to the destruction of pagan cities. Probably it is the source from whence Egypt and Assyria derived material for statuary art. The highlands beyond the strip of low coast are called Akaba. The approaches to them

are formed by a series of short water-course valleys, which contain the first stages of the caravan routes into the interior. The Akaba consists of a wide expanse of flat, featureless plateau, without a habitation or even sign of life—waterless and waste—but broken by occasional masses of flat tableland formation, which lie superincumbent on the lower plain about 80 feet high. On the top level of the Akaba (a little over 4000 feet above sea), is a wide scattering of small black basaltic stones, which rest on the sandstones and limestones of which the range is formed. In the gullies cut out of these tableland formations (which are the higher level or upper flats of the Akaba), as also in the valleys approaching the plateau, the myrrh and frankincense trees, with various forms of mimosa, are to be found. It is curious that the Beduins, who own the plateau, do not themselves gather the produce of the trees, but let districts out to the Somalis, who come in due season to collect the frankincense. The air of the plateau is fresh, keen, and invigorating. The similarity of its conformation to some parts of Abyssinia is striking; and it appears that many points of similarity are also to be noted between the coasts of Southern Arabia and those of Southern Baluchistan. From the Akaba many valleys dip with rapid and sudden descent, flanked by steep red sandstone cliffs, into the main central depression of Hadramut. So steep, and so different from valleys whose formation is due to erosion, are these gates of Hadramut, that it seems possible that they are but branches of a fiord, or arm of the sea, which once filled in the whole Hadramut depression. The upper valley of the Hadramut, round about its capital of Shibam and the courtly residence of its chief at Al Katan, is a land of cultivation and prosperity, of palm groves and towns and palaces, flourishing chiefly on the basis of wealth acquired in India. The sultan, who is the head of the Al Kaiti family of the Tafi tribe, is jemadar or general of the Arab regiments in the service of the Nawab of Haidarabad. This connexion with India is the secret of the wealth of the Al Kaiti family. The dwellers in the towns, and the cultivators of Hadramut belong to races of Arabs who are of later importation into the country than the Beduin. The chief tribes are the Tafi, Ketri, Minhali, Amri, and Tamini, who are constantly at war with the Beduin. The Beduin, who are scattered in wild tribes all over the country, are the caravan leaders and the carriers, rearing their own camels, and owning large territories in the highlands. They are numerous and powerful, never living in tents like the northern Beduin. The richer amongst them occupy houses, and the poorer, caves. The Sharifs and Saiads are an important hierarchy, tracing their descent from the prophet, and exacting the homage of all who are under their widespread influence. They boast a pedigree purer than that of any other Saiad family in Arabia. They are dwellers in towns and cities. The half-bred and imported African slaves form the fourth class of this mixed community. They are all of them Mahommedans, many of them wealthy, and some superior in education to their masters. The tillers of the soil, personal servants, and soldiers of the chiefs mostly belong to this class.

The name Ad is given in the Koran to the Sabæan inhabitants of Southern Arabia, and is still recognized by the modern inhabitants. Within the limits of the coast district there is no evidence of Addite ruins, a circumstance which confirms the opinion that the ancient trade in frankincense was carried on chiefly by the caravan road passing eastwards from Aden to Hadramut and Oman, very little use being made of the harbours and ports of the sterile coast. The movable, wind-blown sand which collects in masses in the centre of the valleys, has probably long ago buried such ancient ruins as date from Himyaritic times, and all that is now observable is to be found on more elevated sites above the plain. A distinct connexion is to be traced between some of the rude stone relics of the past on which inscriptions exist, and those evidences of sun-worship which were found by Bent at Zimbabwe in Mashonaland, where the arrangement of rocks and stones possesses a similar system of orientation. Of the intimate connexion, if not actual relationship, which existed many centuries before our era between the Sabæans of Southern Arabia and those Arab people who worked the gold-mines of Mashona, and built forts to protect them, there can be little doubt. In the Wadi Sher, which leads northwards from the head of the Hadramut into the central districts, there exist the remains of at least one great Himyaritic town, with traces of megalithic buildings

Antiquities.

and a rock exhibiting Himyaritic inscriptions. This appears to have been an important position on the great caravan route between east and west. Large unhewn stones of the dolmen type, decorated on the inside with geometric patterns similar to those found in Mashonaland, together with buildings of extreme antiquity far anterior to those of other Himyaritic remains around them, also exist in the Wadi Sher. The general result of these discoveries is greatly to enlarge our views of the extent of ancient Sabæan colonization in the Eastern world, a result which is still further supported by the remarkable similarity which exists between the great irrigation works to be found in Yemen and those which yet require further investigation in Southern Baluchistan.

The remarkable connexion between the fauna and the flora of Arabia and those of the Somali country and Abyssinia, no less than the curious analogies between geological and topographical construction in the physiology of the two countries, points to a prehistoric land connexion between them on the south, as well as the north, of the Red Sea, which may possibly have been coeval with the land connexion between India and Southern Africa. The link forged in geologic ages never seems to have been entirely broken, and nothing has served to give emphasis to previous evidence on this subject more than the Zimbabwe discoveries of Theodore Bent. It is certain that the ruins and the relics in them (amongst which were found fragments of Persian and Celadon china, such as may still be found in quantities on the coast of Makrán and of the Persian Gulf) are not in any way connected with any African race. We also know that for many centuries before our era the Red Sea was alive with the ships and commerce of Arabia. Arab ships brought spices from India and the "Cania" tree from China; and "Arabian" gold is celebrated in the writings of the very earliest historians. Very little gold ever came from Arabia, but in Africa it was produced in large quantities (both from alluvial and quartz sources) from the earliest ages. There can be little doubt that the builders of Zimbabwe came from the Arabian Peninsula.

Although no recent travels or explorations in Yemen have added greatly to the mass of scientific information collected by Glaser, Schweinfurth, and Playfair, we have acquired a better knowledge of the chief geographical features of that country from the adventurous journey of W. B. Harris in 1892, supplemented by the researches of the Indian surveyors in the Aden district about the same period, and the earlier travels of General F. T. Haig in 1887, than we formerly possessed.
